selective extraction, while deep eutectic solvents offer tunable polarity and biodegradability, making them particularly attractive for food-grade applications. Applied to olive pomace, grape marc, coffee husks, and cereal brans, these approaches yield extracts rich in antioxidants, fibers, and flavonoids, while similar techniques have significantly increased polyphenolic recovery from pomegranate peels and improved extraction of phenolic acids from sunflower husks, which otherwise remain underutilized (Hasnaoui et al., 2014; Karunajeewa et al., 1989). Yet, beyond extraction, the stability and bioavailability of recovered compounds remain bottlenecks, prompting growing interest in encapsulation systems such as nanoemulsions, liposomes, and polysaccharide-based carriers. These delivery systems protect phenolics and flavonoids from degradation, improve solubility, and enhance controlled release, thereby extending their functional performance in food and nutraceutical contexts. Encapsulated grape pomace polyphenols have demonstrated prolonged antioxidant activity in beverages, while edible films enriched with pomegranate peel extracts extended the shelf life of perishable fruits, reinforcing their role in natural food preservation (López-Astorga et al., 2025; Vikrant et al., 2024). Functional integration of by-products into food matrices further supports their valorization: sunflower husk fibers incorporated into bakery products improved hydration, dough texture, and overall fiber content, producing breads with enhanced nutritional quality (Karunajeewa et al., 1989), whereas pomegranate peel powders enriched in dietary fiber fractions and phenolic compounds not only contributed to antioxidant activity but also slowed glucose diffusion, highlighting potential applications in glycemic control (Hasnaoui et al., 2014). Similar valorization pathways are evident across other agricultural residues, where olive pomace and grape marc extracts are used as additives in dairy and beverages, coffee husks yield caffeine- and antioxidant-rich fractions for nutraceuticals and cosmetics, and cereal brans provide arabinoxylans and β -glucans with prebiotic effects. However, despite technical advances, significant barriers remain to industrial translation, notably variability in raw materials due to cultivar, season, and environment, which complicates standardization and consistent product performance. For example, pomegranate peel fiber content can range from 33% to over 60% of dry matter depending on genotype and growing conditions, while sunflower husks exhibit fluctuating phenolic acid profiles shaped by cultivation and processing variables (Hasnaoui et al., 2014; Karunajeewa et al., 1989). Such heterogeneity requires robust quality-control frameworks, predictive models, and possibly blending strategies to ensure reproducibility. Scalability of green extraction technologies also presents hurdles, as methods such as ultrasound and microwave need adaptation to continuous, high-throughput industrial systems. On the regulatory and consumer side, the perception of “waste-derived” ingredients demands transparent labeling, rigorous safety assessments, and clinical validation to build confidence, while regulatory pathways must evolve to better accommodate by-product-derived bioactives (Mansour et al., 2023). Nevertheless, the research trajectory strongly aligns with the United Nations Sustainable Development Goals, particularly SDG 12 on responsible consumption and production and SDG 2 on zero hunger, by transforming residues into nutrient-rich resources while reducing waste streams. Moreover, replacing synthetic additives with natural preservatives from pomegranate peels or sunflower husks directly contributes to SDG 3 on good health and well-being by offering safer dietary options and lowering exposure to chemical preservatives. Large-scale collaborative programs provide encouraging examples: PRIMA-funded Mediterranean initiatives integrate local by-products into sustainable value chains by combining green extraction, encapsulation, and feed applications, fostering technology transfer, promoting rural economies, and strengthening resilience in agri-food systems.

Nutritional Composition of Sunflower Seed husks and Pomegranate Peels

The valorization of agro-industrial by-products such as sunflower husks (also referred to as hulls) and pomegranate peels has gained strong momentum in recent years due to their rich

nutritional profiles and their alignment with sustainable food system strategies and circular economy practices (Gulya, 2004; Hasnaoui et al., 2014). Detailed proximate analysis highlights distinct compositional differences between these two matrices, largely shaped by their botanical origins and the processing conditions from which they emerge. Sunflower seed husks typically exhibit very low moisture content, usually in the range of 4–5%. Such dryness makes them highly stable during long-term storage, transport, and handling, while also enhancing their suitability for subsequent extraction of bioactive compounds. This contrasts sharply with pomegranate peels, which are characterized by a very high water content, often exceeding 80%. The latter property makes them more prone to microbial spoilage if not rapidly dried, lyophilized, or otherwise stabilized. As a result, processing strategies for pomegranate peels often need to prioritize moisture reduction to ensure the preservation of functional components and to maintain bioactive potency (Figure 1).

Ash content in both by-products is relatively similar, generally around 3–4%. This value reflects their moderate but still nutritionally relevant mineral contribution, with elements such as potassium, magnesium, and calcium being particularly abundant. These minerals not only support general dietary requirements but also serve as cofactors in enzymatic pathways critical to both human and animal physiology.

The lipid profiles of the two materials diverge markedly. Sunflower seed husks contain approximately 2–3% lipids, with unsaturated fatty acids such as linoleic acid representing the dominant fraction (Gulya, 2004). This aligns with their role as a residual product of oilseed processing, providing potential for incorporation into formulations where essential fatty acids can deliver added health value. In contrast, pomegranate peels generally contain less than 1% lipids, underscoring their classification as a carbohydrate-dominant matrix with inherently lower caloric density. From a formulation perspective, this makes pomegranate peels more suitable for functional applications requiring bioactive polyphenols or polysaccharides rather than lipid enrichment (Hasnaoui et al., 2014).

Protein levels, surprisingly, display close similarity across both by-products, with concentrations generally reported between 13 and 15 mg/mL (Ben Jemaa et al., 2022). While not sufficient to position these matrices as primary protein sources, such levels nonetheless highlight their supplementary potential. They can thus be integrated into feed formulations to improve protein balance or into specialized food products where additional plant-based proteins are desirable. The amino acid composition, though less extensively studied, suggests that these proteins could contribute bio-functional properties, including antioxidant activity or foaming capacity, when isolated and characterized further.

Total soluble sugars represent another shared attribute. Both sunflower husks and pomegranate peels contain approximately 1.8–2.0 mg/g of soluble carbohydrates. These sugars, though present in modest quantities, are of interest for biotechnological valorization. They can act as precursors in fermentation-based processes, contribute to the development of natural sweeteners, or serve as substrates for microbial bioconversion into higher-value compounds. This equivalence in sugar content between the two by-products also indicates potential for combined or complementary use in integrated biorefinery concepts.

Overall, these compositional features position sunflower husks as lipid- and stability-oriented resources, with particular utility in feed, nutraceutical, or functional food applications where fatty acid enrichment and long-term preservation are prioritized. Pomegranate peels, conversely, emerge as water-rich, carbohydrate- and polyphenol-focused resources requiring immediate stabilization but offering high yields of soluble bioactives for applications in beverages, coatings, or extracts. Both matrices, in their respective domains, contribute meaningfully to the portfolio of agro-industrial by-products that can be harnessed for sustainable nutrition and health-oriented innovations.

Figure 1. Nutritional Composition of Sunflower Seed husks and Pomegranate Peels.

Antioxidant Potential and Extraction Efficiency

Antioxidant activity has emerged as a central pillar in the valorization of agri-food by-products, reflecting both consumer and industrial demand for natural preservatives and health-enhancing compounds (Falleh et al., 2020). The search for plant-based alternatives to synthetic additives is particularly relevant in food, nutraceutical, and pharmaceutical sectors, where oxidative degradation limits product quality, safety, and shelf life. Consequently, by-products once regarded as waste are increasingly investigated as reservoirs of functional molecules, particularly polyphenols, flavonoids, and lipid-soluble antioxidants, capable of mitigating oxidative stress and associated chronic pathologies. Among the by-products recently studied, sunflower seed husks and pomegranate peels present contrasting yet complementary attributes. Evaluations using the DPPH radical scavenging assay demonstrate that sunflower seed husks possess a strong antioxidant capacity, reaching inhibition rates of nearly 40%. This level of activity is approximately fivefold higher than that of pomegranate peels, which display values closer to 9%. Such disparity is commonly attributed to the chemical nature of the antioxidant molecules present. Sunflower seed husks are especially rich in lipid-associated antioxidants, notably tocopherols and certain phenolic acids, that excel in neutralizing reactive oxygen species and delaying oxidative chain reactions in lipid systems (Mansour et al., 2025). These compounds confer a specific advantage in food matrices where lipid oxidation represents a primary degradation pathway. However, antioxidant capacity alone does not determine the overall feasibility of by-product recovery. Extraction yield plays a decisive role in defining economic viability. In this respect, pomegranate peels significantly outperform sunflower seed husks. Reported yields for pomegranate peels approach 34%, compared to approximately 9% for sunflower husks (Hasnaoui et al., 2014). This difference arises from structural and compositional factors. Pomegranate peels possess a porous cellular structure and high levels of water-soluble phenolic compounds, which allow solvents to penetrate more effectively and release target metabolites during extraction (Mansour et al., 2023). Sunflower husks, by contrast, contain more compact, lignocellulosic material that limits solvent accessibility, reducing extractable fractions despite their strong antioxidant potential per unit of dry matter. The tension between antioxidant strength and extraction yield is not unique to these two

matrices. Similar observations have been documented for date perianths and squash peels, where optimization strategies are required to maximize recovery efficiency without compromising bioactivity (Mejri et al., 2025; Mansour et al., 2025). Advanced statistical tools, particularly response surface methodology (RSM), have been applied to refine extraction parameters, balancing solvent polarity, time, and temperature to enhance both yield and functional activity. These approaches underscore the need for integrative optimization frameworks when scaling up by-product valorization processes. Beyond laboratory assays, the practical significance of these antioxidant-rich extracts lies in their wide-ranging applications. In food systems, sunflower seed husk extracts could serve as natural stabilizers for lipid-rich products such as edible oils, margarines, or bakery items, where they would delay rancidity and extend shelf life. Conversely, pomegranate peel extracts—with their high extraction yield and abundance of hydrophilic phenolics—may be more suitable for fortification of aqueous systems, including fruit juices, teas, or functional beverages. The cosmetic sector also presents an attractive avenue, as phenolic-rich extracts from pomegranate peels can be incorporated into creams or serums to mitigate oxidative skin damage and promote anti-aging effects. Health-promoting effects represent another crucial dimension. Dietary incorporation of these extracts may contribute to the prevention of chronic disorders linked to oxidative stress, including cardiovascular diseases, metabolic syndrome, and certain cancers (Falleh et al., 2020). This dual functionality—technological as food preservatives and biological as health-promoting agents—places sunflower husks and pomegranate peels at the crossroads of circular economy principles and functional food innovation.

Phenolic Profiles and Bioactive Diversity

High-performance liquid chromatography (HPLC) provides critical insights into the phenolic profiles of agri-food by-products, revealing the biochemical diversity that underpins their bioactivity. Sunflower seed husks and pomegranate peels, in particular, stand out as contrasting yet complementary reservoirs of phenolics, positioning them as “bioactive goldmines” for targeted applications in food, pharmaceutical, and cosmetic industries. Analytical results highlight the dominance of flavonoids and ellagitannins in pomegranate peels, consistent with their well-documented antioxidant and antimicrobial capacities. Key compounds quantified include catechin (336.58 µg/g), rutin (275.52 µg/g), and ellagic acid (153.08 µg/g), alongside moderate levels of chlorogenic acid (55.55 µg/g) and syringic acid (28.83 µg/g). These molecules are mechanistically linked to the modulation of oxidative pathways and the inhibition of microbial enzymes, supporting both anti-inflammatory activity and pathogen resistance (Mansour et al., 2023). Catechin, for example, is renowned for its free-radical scavenging ability, while ellagic acid contributes to DNA protection and anti-proliferative effects. Rutin adds vascular-protective benefits, making pomegranate peel extracts attractive for nutraceutical formulations. Sunflower seed husks, in contrast, exhibit a markedly different phenolic spectrum. Their profiles are dominated by phenolic acids, particularly resorcinol (856.70 µg/g) and sinapic acid (110.52 µg/g), with only minor contributions from catechin (47.07 µg/g). These compounds reflect the physiological role of husks in providing UV protection and maintaining structural integrity of oilseeds. Resorcinol, in particular, is a multifunctional molecule with antioxidant, antimicrobial, and dermatological relevance, often used in pharmaceutical and cosmetic formulations. Sinapic acid enhances oxidative stability in lipid systems, suggesting that sunflower husk extracts may be well-suited for preserving oils and fat-rich foods. Interestingly, chromatographic data also revealed unidentified peaks. In sunflower husks, a non-identified compound was detected at 4.567 min (NI, 266.19 µg/g), while pomegranate peels exhibited a distinct peak at 9.34 min (NI, 331.21 µg/g). These findings point to the presence of yet-uncharacterized bioactives that could broaden the functional repertoire of these by-products. Advanced structural elucidation through techniques such as LC-MS/MS

and NMR will be necessary to determine their identity and potential bioactivity. Such discoveries would not only expand the scientific understanding of phenolic diversity but could also reveal novel molecules of industrial significance. The phenolic heterogeneity observed here aligns with studies on other by-products such as date seed husks and squash peels, where compositional differences are shaped by varietal, environmental, and processing factors (Mejri et al., 2025; Mansour et al., 2023). This diversity underscores the possibility of tailoring extraction strategies to optimize the recovery of specific compounds with desired biological functions. For example, solvent polarity and extraction temperature can be fine-tuned to preferentially target flavonoids, ellagitannins, or phenolic acids, depending on the intended application. Moreover, combining extracts from sunflower husks and pomegranate peels could provide synergistic advantages. While sunflower husks contribute lipid-soluble stability via phenolic acids, pomegranate peels supply a rich arsenal of flavonoids and ellagitannins with water-soluble antioxidant and antimicrobial effects. Such complementary interactions may yield broad-spectrum formulations capable of enhancing oxidative stability in diverse food matrices. To preserve the integrity of these sensitive compounds, encapsulation technologies—such as nanoemulsions, liposomes, or biopolymer-based carriers—are increasingly advocated to enhance stability, bioavailability, and controlled release in functional foods or supplements (Mansour et al., 2023).

Table 1. Identification and quantification of phenolic compounds from sunflower seed husks and pomegranate peels. Values are presented as milligrams Gallic acid equivalent per gram of extract (mgGAE/g E).

RT (min)	Sunflower Seed Husks	Pomegranate Peels	Compound
4.567	266.19	-	NI eqAG
9.34	-	331.21	NI eqAG
10.67	-	55.55	Chlorogenic Acid
11.069	856.70	-	Resorcinol
11.85	-	336.58	Catechin
12.482	47.07	-	Catechin
14.91	-	28.83	Syringic Acid
16.34	-	275.52	Rutin
17.54	-	153.08	Ellagic Acid
18.955	110.52	-	Sinapic Acid

Antimicrobial Activity and Food Safety Implications

The antimicrobial potential of plant by-products is gaining traction as a response to the escalating threat of foodborne pathogens and antibiotic resistance (Falleh et al., 2020). Both sunflower seed husks and pomegranate peels exhibit inhibitory activity against *Staphylococcus aureus*, a frequent contaminant in dairy and meat products. Sunflower husks achieve approximately 29% growth inhibition—nearly double that of pomegranate peels (14%)—based on the methodology of Ben Jemaa et al. (2022). This stronger performance may be linked to

their resorcinol and sinapic acid content, known to compromise bacterial membranes and disrupt quorum sensing (Falleh et al., 2020). Pomegranate peels, although less potent, contribute ellagic acid and catechin, which act through phenolic-protein interactions to exert bacteriostatic effects against Gram-positive bacteria (Hasnaoui et al., 2014). Evidence from parallel research, including cedar essential oils and date by-products, underscores the utility of response surface methodology in enhancing antimicrobial activity (Ben Jemaa et al., 2022; Mejri et al., 2025). Applying similar optimization approaches to sunflower and pomegranate matrices could further maximize their bioactive potential. The antimicrobial relevance of these by-products extends beyond *S. aureus*. Pomegranate peel polyphenols have demonstrated inhibitory effects against *Escherichia coli*, where incorporation into chitosan-based edible films markedly increased inhibition zones (27.67 mm) compared to negligible activity in extract-free films (Kumar et al., 2021). The mechanism, as with *S. aureus*, involves membrane destabilization and quorum sensing interference, reducing pathogen virulence. In parallel, sunflower hull extracts have shown significant activity against *E. coli* O157:H7, *S. aureus*, *Bacillus cereus*, *Listeria monocytogenes*, and *Salmonella typhimurium*, with inhibition zones ranging from 10 to 22 mm (Taha et al., 2012). These findings reinforce the promise of sunflower husks and pomegranate peels as broad-spectrum antimicrobial agents with applications in food preservation. Their inclusion in food or feed systems could reduce reliance on synthetic additives, aligning with consumer demand for “clean-label” solutions. By extending shelf life and minimizing risks associated with chemical preservatives, they address both safety and sustainability goals (Falleh et al., 2020). From an agricultural perspective, their application is equally appealing. Pomegranate peel extracts, when integrated into fruit-derived antimicrobial systems, enhance post-harvest quality management, while sunflower husks can reinforce grain-based bio-preservation strategies.

Functional By-Products for Sustainable Ruminant Diets

The translation of laboratory evidence into practical applications in animal nutrition is steadily advancing, with particular emphasis on valorizing agricultural by-products as functional feed components. Within the framework of the PRIMA-MEDGOAT project, special attention has been directed toward pomegranate peel polyphenols, which are increasingly recognized as promising feed additives capable of enhancing livestock health and productivity. These compounds exhibit potent antioxidant properties that can mitigate oxidative stress, improve gut function, and strengthen immunity in ruminants such as calves, goats, and beef cattle (Safari et al., 2018; Varma et al., 2018).

Pomegranate peel is rich in phenolic compounds and hydrolyzable tannins, conferring multiple benefits when incorporated into ruminant diets. Its supplementation at levels of approximately 2–4% of feed has been associated with improved nutrient digestibility, enhanced rumen fermentation efficiency, and reduced oxidative biomarkers. In dairy systems, inclusion of pomegranate peel has been linked to increased milk yield and improved milk quality, suggesting a nutraceutical effect that extends beyond basic nutrition (El-Ashry et al., 2019; Safari et al., 2018). In young calves, dietary supplementation reduced the prevalence of intestinal parasites, reflecting the anthelmintic potential of peel-derived tannins. Meanwhile, across different livestock categories, blood antioxidant status improved significantly, indicating systemic protective effects against oxidative imbalance (Varma et al., 2018).

The versatility of pomegranate peel also supports diverse modes of use. It can be provided fresh, incorporated as a dried extract, or preserved in silage form to ensure longer storage and easier integration into feed rations. Such flexibility enhances its applicability across farming systems, whether intensive or semi-intensive. Notably, beyond improvements in health indicators, pomegranate peel supplementation has been shown to promote weight gain and optimize meat quality in small ruminants, providing added value for producers. These outcomes align with the

broader objectives of sustainable livestock management, where functional feed ingredients contribute simultaneously to animal health, productivity, and product quality.

In parallel, sunflower seed hulls represent another by-product with growing interest for ruminant feeding, though their contribution is primarily structural rather than bioactive. Composed of roughly 50% crude fiber, 7% protein, and with a dry matter digestibility of about 18%, sunflower hulls are best suited as a source of insoluble fiber (Alharthi et al., 2021; Alobre et al., 2021). When included at levels ranging from 15% to 35% of total dietary dry matter, and balanced with protein-rich feeds, they effectively support rumen function by stimulating chewing activity and saliva secretion, which are essential for buffering rumen pH. Their role as a bulky roughage source helps maintain gut motility and microbial balance.

Animal feeding trials indicate that sunflower hulls can be safely incorporated into the diets of goats, sheep, and cattle without negative impacts on growth performance. In fact, moderate inclusion has been associated with stable weight gain and overall improved digestive health. While they lack the bioactive potency of polyphenol-rich pomegranate peels, sunflower hulls serve as a cost-effective roughage alternative that contributes to diet formulation flexibility, particularly in regions where high-quality forage may be limited.

Socio-Economic and Environmental Perspectives

The valorization of agro-industrial by-products plays a pivotal role in advancing circular economy models by transforming waste streams into functional, marketable products. Sunflower husks and pomegranate peels, often discarded in bulk during processing, represent abundant raw materials that can be redirected into high-value sectors such as food, feed, nutraceuticals, and cosmetics. This shift not only reduces the volume of agricultural residues but also lessens the environmental footprint of agro-industrial chains. By diverting husks and peels from landfills or uncontrolled disposal, greenhouse gas emissions linked to decomposition are minimized, while risks of soil leachates and water contamination are mitigated. From an economic standpoint, valorization introduces new income opportunities for farmers, cooperatives, and small processors, particularly in Mediterranean regions where sunflower and pomegranate cultivation is widespread. Local industries stand to benefit from cost savings on waste management and from the creation of new product lines, thereby increasing competitiveness. Moreover, the integration of such by-products into feed or functional food systems supports rural development by strengthening agro-industrial linkages and reducing dependence on imported additives. Nevertheless, several challenges constrain large-scale adoption. Regulatory acceptance requires rigorous safety assessments and standardized quality controls, while consumer confidence hinges on transparent labeling and verified health claims. Cost-competitiveness with synthetic additives also remains a barrier, given that extraction, processing, and encapsulation technologies can be resource-intensive. Bridging these gaps demands coordinated strategies: targeted subsidies, supportive policies, and investment in green technologies to reduce production costs.

International collaborations offer a strong pathway forward. EU-funded PRIMA initiatives illustrate how transnational partnerships can catalyze technology transfer, foster knowledge exchange, and build capacity for sustainable bio-based industries. By integrating scientific advances with socio-economic incentives, such programs highlight the potential of agro-industrial by-products to drive both environmental protection and regional economic resilience.

Challenges and Future Prospects in By-Product Valorization

Despite the growing evidence supporting the bioactive potential of agro-industrial by-products, several obstacles limit their transition from laboratory to large-scale application. A major challenge arises from variability in chemical composition, which can differ significantly

depending on cultivar, growing conditions, harvest period, and storage practices. Seasonal and regional fluctuations alter the concentration of polyphenols, flavonoids, and tannins, thereby influencing both antioxidant activity and extraction yields. Such inconsistency complicates industrial standardization and requires robust quality-control protocols to ensure reproducibility (Mejri et al., 2025). Extraction efficiency represents another critical bottleneck. Conventional solvent-based techniques often suffer from low yields, high solvent consumption, and potential degradation of thermolabile compounds. To address these limitations, green extraction technologies—such as ultrasound-assisted extraction (UAE), microwave-assisted extraction (MAE), and pressurized liquid extraction—are gaining traction. UAE, in particular, has shown promise in enhancing mass transfer, reducing solvent use, and improving the recovery of phenolic compounds without compromising their functional integrity (Mejri et al., 2025). The integration of such methods not only improves sustainability but also aligns with industrial demands for cost-effective and eco-friendly processing. Beyond technological hurdles, regulatory and consumer-related issues must also be carefully considered. Ingredients derived from “waste” streams may face skepticism, with consumers questioning their safety, quality, or nutritional value. Transparent labeling, coupled with rigorous toxicological evaluations and clinical validation of health benefits, is essential to build trust and ensure compliance with food safety regulations (Mansour et al., 2023). Clear communication strategies that emphasize sustainability and the valorization of natural resources can further enhance consumer acceptance. Future research directions should move toward interdisciplinary approaches that integrate analytical chemistry, food technology, and biomedical sciences. Stability studies are urgently needed to evaluate how processing, storage, and formulation affect the bioactivity of recovered compounds. In vivo trials, both preclinical and clinical, will be critical for confirming the physiological relevance of in vitro findings, particularly regarding antioxidant, antimicrobial, and anti-inflammatory effects (Falleh et al., 2020). Additionally, encapsulation technologies should be explored to enhance the stability and bioavailability of phenolic extracts, ensuring their efficacy in complex food or pharmaceutical matrices.

International collaborations provide a powerful mechanism to accelerate progress in this domain. Programs such as *MedGoat-H2020* demonstrate how transnational projects can facilitate technology transfer, foster harmonization of extraction protocols, and enable shared access to advanced infrastructure. Such initiatives are particularly relevant for the Mediterranean region, where large quantities of by-products like pomegranate peels and sunflower husks are generated annually. By linking scientific innovation with socio-economic priorities, these collaborations strengthen the value chain from farm to market. Ultimately, the valorization of by-products must be viewed not only as a technological challenge but also as a socio-environmental imperative. Aligning with the United Nations Sustainable Development Goals, particularly those targeting zero waste, responsible consumption, and food security, by-product utilization represents a pathway toward resilient, low-carbon, and resource-efficient food systems. With continued investment in green technologies, rigorous safety validation, and international cooperation, the full potential of these bioactive resources can be unlocked, transforming agricultural residues into drivers of sustainable development.

CONCLUSION

The comparative assessment of sunflower seed husks and pomegranate peels clearly demonstrates their remarkable potential as bioactive reservoirs. Both by-products exhibit valuable nutritional traits, distinct phenolic signatures, and complementary biological activities. Sunflower husks stand out for their strong antioxidant and antimicrobial effects, while pomegranate peels provide higher extraction yields and richer flavonoid content. This duality suggests that integrated valorization strategies, combining the strengths of both matrices, could

yield multifunctional formulations for food preservation, nutraceutical development, and cosmetic applications. The advances in green extraction and encapsulation technologies further support their transition from laboratory findings to industrial adoption. Beyond technical advantages, the valorization of these by-products contributes to sustainability and circular economy goals, reducing agro-industrial waste while generating economic opportunities in rural and processing communities. Yet, successful integration requires tackling challenges linked to raw material variability, regulatory approval, and consumer acceptance. In conclusion, sunflower husks and pomegranate peels should no longer be regarded as low-value residues but as strategic raw materials for the next generation of eco-innovative products. Their effective use aligns with global efforts to promote health, sustainability, and responsible resource management.

ABSTRACT

In this study, the aim was to determine the effects of sous-vide processing on the quality characteristics of apple, quince and pumpkin, which are widely consumed fruits in Turkey. The sous-vide method is a gentle cooking technique that uses low temperatures and long cooking times in vacuum-sealed packaging to preserve nutritional value, color, texture and sensory quality. In this research, sous-vide cooking was applied at predetermined temperature-time combinations and the results were compared with the conventional steaming method. Additionally, the changes during storage were also evaluated. The findings revealed that, compared to conventional cooking, sous-vide processing helped to better preserve the color and texture of fruits, reduced cooking losses, and improved consumer sensory acceptance.

Keywords: Sous-vide, fruit, color, texture, sensory analysis, storage

INTRODUCTION

In the food industry, it is becoming increasingly important to prepare products in line with consumer expectations while maintaining both healthy and quality characteristics. Sous-vide method is a heat treatment technology based on the principle of low temperature and prolonged cooking in vacuum packaging. This method contributes to the preservation of particularly heat-sensitive nutritional compounds, reducing textural losses and ensuring microbial safety. Fruits such as apples, quince and pumpkin are frequently cooked and consumed in different forms such as desserts and jams in our country. However, studies on cooking these products by sous-vide method are very limited.

In this context, in this study, quality parameters such as color, texture, sensory quality, moisture content, cooking efficiency and storage stability were evaluated by applying sous-vide process to apple, quince and pumpkin at specified temperatures and times. Comparative analyses with the traditional steaming method revealed the feasibility of sous-vide as an alternative cooking technology. This study aims to contribute to the development of fruit-based ready-to-eat products and to extend product shelf life.

LITERATURE SUMMARY

2.1. Sous-Vide Cooking Technique

Sous-vide means "under vacuum" in French and is a heat treatment method based on the long-term cooking of food in airtight plastic bags at controlled low temperatures (usually between 50-95 °C) (Baldwin, 2012). During this process, the food is first placed in a vacuum bag, vacuum-sealed to remove oxygen, and then cooked in a precisely temperature-controlled water bath or steam oven for the targeted time (Schellekens, 1996).

The main difference of the sous-vide technique is that the risk of overcooking at the targeted temperature is eliminated by precisely controlling the temperature. In this way, thermal reactions such as protein denaturation, starch gelatinization and enzyme inactivation take place in a controlled manner (Kathuria et al., 2022).

The method offers many advantages over conventional cooking methods in terms of color, texture, nutrient preservation and microbiological safety (Creed, 1998). Especially in vegetables and fruits, the loss of heat sensitive compounds such as vitamin C, phenolic compounds and carotenoids is minimized (Stea et al., 2007). Ghazala et al. (1996) reported that color preservation and soft texture were better achieved when apples were cooked by sous-vide method. Iborra-Bernad et al. (2015) observed less structural distortion and better texture integrity in vegetables such as potatoes and carrots.

Sous-vide method is also important for food safety. The absence of oxygen in the vacuum environment and precise temperature control are critical, especially for anaerobic pathogens such as *Clostridium botulinum*, and a safe product is obtained when the pasteurization time and temperature are set appropriately (Baldwin, 2012).

However, the method also has some limitations. Long cooking times can increase energy consumption. Furthermore, the microbial safety of the foodstuff depends on the quality of the vacuumization and the accuracy of the temperature control system. This control can be difficult to achieve in domestic applications (Singh et al., 2023).

In conclusion, the sous-vide method is a promising technology for vegetable and fruit products, especially for the preservation of sensory and nutritional properties. However, its applicability on an industrial scale needs to be optimized and product-based validation studies need to be continued.

Figure 1 Vestel Sous-vide Cooking Oven and 3D Drawing

2.2. Usage Areas of Sous-Vide Applications

While the sous-vide method is widely used especially in protein foods, in recent years it has also been investigated in vegetable and fruit groups to improve quality. Stanikowski and Michalak-Majewska (2021) compared sous-vide, boiling and steaming methods in root vegetables and reported that sous-vide was the most advantageous method in terms of color, texture and preservation of bioactive compounds.

In a comprehensive review summarizing the effects of sous-vide on vegetables and fruits, Kathuria et al. (2022) found that this method causes less cellular damage at low temperature and is superior in terms of sensory properties as well as microbial safety. It was emphasized that the sous-vide method created significant differences compared to traditional methods, especially in the preservation of color and nutritional values.

Yılmaz and İlyasoğlu (2023) reported that sous-vide technique positively affected both physical and sensory quality in vegetables such as green beans and pumpkin and provided a more stable structure in the storage process. Since products obtained by sous-vide cooking are cooked at lower temperatures, the cell walls are less damaged, which allows the textural integrity to be preserved. This is especially noticeable in hard textured fruits such as quince.

In a study conducted by Najman et al. (2021), it was found that sous-vide process contributed to the preservation of phenolic compounds and improved the functional properties of the product in various physical-chemical analyzes performed on quince samples.

Singh et al. (2023) emphasized that sous-vide technique is a process that improves food quality in general and evaluated it as an effective method in terms of both microbiological safety and stability of functional components. In the study, it was stated that low temperature applications had positive effects on sensory quality and bioactive content, especially in fruits and vegetables.

Roca and Brugués (2007) reported that products prepared by the sous-vide method can largely maintain their sensory parameters such as color and taste when stored at -18°C as long as microbial safety is ensured.

2.3. Comparison of Sous-Vide and Traditional Cooking Methods

The main differences between sous-vide and conventional cooking methods focus on critical parameters such as the type of heat treatment, temperature control, the amount of oxygen to which the product is exposed and nutrient losses. While traditional methods (boiling, baking, steaming, etc.) generally cook foods at high temperatures (100 °C and above) for short periods of time, sous-vide method is based on cooking at low temperatures (50-95 °C) for long periods of time. This difference has significant effects on the preservation of nutrients, color pigments, textural structures and volatile aromatic compounds (Creed, 1998; Stea et al., 2007).

One of the most obvious advantages of the sous-vide method over conventional cooking techniques is the minimization of the loss of heat-sensitive compounds. In a study conducted by Stea et al. (2007), it was reported that folate, carotenoid and α -tocopherol levels in vegetables were preserved to a higher extent when cooked by sous-vide method compared to boiling and steaming methods. Similarly, Iborra-Bernad et al. (2015) observed better color stability and less structural degradation in root vegetables such as potatoes and carrots after sous-vide cooking.

Significant differences were also observed in terms of color parameters. Ghazala et al. (1996) reported that sous-vide cooking of apple samples resulted in a smaller reduction in L* (lightness) than conventional boiling, which was favorable for consumer perception. Similarly, Stanikowski and Michalak-Majewska (2021) found more vibrant colors and higher levels of bioactive compounds in root vegetables cooked sous-vide.

In terms of texture, low-temperature cooking allows the cell walls to break down more slowly, resulting in a soft but not disintegrating structure. This is particularly evident in hard fruits/vegetables such as quince, apples and carrots (Singh et al., 2023). Samples cooked sous-vide can offer a more homogeneous texture and a lower firmness value compared to conventional cooking (Bourles et al., 2009).

In terms of aroma compounds, traditional methods cause more loss of volatile compounds, whereas in sous-vide applications, the aromatic profile is more intense and natural due to the retention of these compounds in the pouch (Kathuria et al., 2022).

However, both methods have their own advantages. While traditional methods offer shorter cooking times, the sous-vide method requires more time and equipment precision. In terms of energy consumption, the long cooking time may be a disadvantage for some applications.

2.4. Ready-to-eat Foods Produced with Sous-Vide and Storage Durability

Today, consumers' time constraints, search for practicality and healthy eating tendencies are increasing the demand for ready-to-eat foods. In this context, foods produced by sous-vide method constitute an important alternative for ready-to-eat products in terms of both minimizing nutrient losses and allowing the product to be cooked in the package and stored for a long time (Singh et al., 2023).

One of the most obvious advantages of products prepared by sous-vide method is that the risk of external contamination is eliminated by cooking the products in vacuum packaging. This packaging can be directly cooled, frozen, or short-term pasteurized without opening the product after cooking to ensure microbial safety (Baldwin, 2012). Reducing the oxygen level in the

vacuum environment also prevents oxidative deterioration and contributes to the preservation of color, aroma and fatty acid profiles (Creed, 1998).

In terms of storage stability, sous-vide products are very advantageous. Roca and Brugués (2007) showed that meat products cooked sous-vide can maintain microbiological safety and sensory quality for up to 28 days at +4 °C. Similarly, Yilmaz and Ilyasoglu (2023) reported that frozen storage at -18 °C after sous-vide cooking of vegetables such as green beans and pumpkin significantly preserved sensory characteristics for 30 days.

In order for sous-vide produced products to be sold on the shelves, the cold chain must be maintained, usually in combination with low-temperature pasteurization. These products are categorized as "chilled ready meals" and can have a shelf life of up to 21-30 days at a temperature range of +2/+4 °C, mostly under refrigerated storage conditions (Kathuria et al., 2022). When stored in frozen form, this period can be up to several months.

Sous-vide products are also advantageous in terms of functional food components, allowing the preservation of vitamins, phenolic compounds and volatile flavors that can break down at high temperatures, thus preserving both the health value and flavor profile of the product (Stea et al., 2007; Najman et al., 2021). In this way, healthier alternatives can be offered for both home consumption and industrial-scale ready-to-eat food production.

As a result, ready-to-eat foods produced by sous-vide method can outperform products produced by conventional methods in parameters such as high quality, long shelf life and microbiological safety. However, critical control points such as chain cooling, hygienic vacuuming and temperature monitoring need to be carefully implemented.

2.5. Apple (*Malus domestica* Borkh.)

Apple is one of the most produced and consumed fruits worldwide. According to FAO data for 2023, world apple production exceeds 90 million tons, while Turkey is among the top 5 producing countries with a production of 4.5 million tons. Apples contain approximately 84-86% water, 10-13% carbohydrates, 0.3% protein and 0.2% fat. It is also rich in vitamin C, potassium, polyphenols and fiber (Boyer & Liu, 2004).

Apple has a high antioxidant capacity thanks to phenolic compounds and flavonoids concentrated especially in the peel. In this respect, apple is considered as a functional food with protective effects against heart diseases, diabetes and some types of cancer (Hyson, 2011). Apple is also a fruit resistant to cooking. Sous-vide cooking practices have been determined to provide minimal loss of nutrients by preserving the textural integrity of apples (Silva et al., 2021).

2.6. Quince (*Cydonia oblonga* Mill.)

Quince is a stone fruit belonging to the Rosaceae family and is generally consumed cooked rather than fresh. Turkey ranks first in quince production, accounting for approximately 25% of the world quince production (TurkStat, 2023). Quince is rich in pectin, tannins, organic acids (malic acid, citric acid), potassium and vitamin C (Rather et al., 2020).

Quince fruit has an astringent taste due to its high tannin content and is usually consumed in dessert form by cooking with flavorings such as sugar, cloves and cinnamon. With the softening of the cell walls during the cooking process, quince gains a characteristic aroma and reddish color (Sharma et al., 2011). Sous-vide cooking allows this transformation to take place in a controlled manner, resulting in a more homogeneous texture and stable color than traditional methods (Ghazala et al., 1996).

2.7. Pumpkin (*Cucurbita moschata* Duchesne ex Poir.)

Pumpkin is a fruit rich in beta-carotene, vitamin C and potassium, which is widely used in products such as desserts and soups during the winter months. This fruit, which has a high fiber content, is also preferred in healthy nutrition programs thanks to its low calorie structure. 100 grams of pumpkin contains about 26 kcal of energy, 9 mg of vitamin C and 1.3 g of fiber (USDA, 2022).

Pumpkin is suitable for pureeing due to its structure that softens when cooked. However, traditional boiling and baking methods can cause dull color and nutrient losses. In studies conducted with sous-vide cooking, it was reported that pumpkin retained brighter color, reduced beta-carotene loss and better preservation of starch structure as a result of prolonged cooking at low temperature (Stea et al., 2007).

MATERIALS AND METHODS

3.1. Material

Quince, apple and pumpkin fruits used in this study were obtained from a local market in Izmir. The fruits were stored at +4°C until use. Sous-vide cooking was carried out in a sous-vide oven provided by Vestel A.Ş. Color, texture and moisture analyses were carried out with the devices in the pilot plant of Ege University Food Engineering Department.

3.2. Determination of Temperature and Time

In this section, examples of sous-vide and conventional cooking temperatures and times reported in the literature for apple, quince and pumpkin are presented. The combinations used in the studies and the results obtained are compiled in tabular form and the temperature-duration profiles in our study are determined. While determining these profiles, it is aimed that the product outputs we will get are in line with the findings in the literature and the expected results.

Table 1 Examples of sous-vide cooking reported in the literature (temperature/time)

Source	Temperature (°C)	Duration (minutes)	Product and Findings
Ghazala et al. (1996)	65, 85	60, 20	Apple; color and hardness analysis
Ortiz-Catalan et al. (2017)	60-90	30-90	Apple; pectin enzyme activity and texture
Najman et al. (2021)	85	45	Quince; phenolic and antioxidant content
Kathuria et al. (2021)	75-95	30-90	Quince and vegetables; general quality parameters
Yilmaz & Ilyasoglu (2023)	90	45	Pumpkin; sensory/chemical analysis
Rinaldi et al. (2020)	~90	40-60	Pumpkin; microstructure and antioxidants
Stea et al. (2007)	85-95	10-30	Vegetables; vitamin and antioxidant protection

Table 2 Experimental plan (temperature / time) applied in sous-vide cooking method

Product	Temperature(°C)	Duration(minutes)
Pumpkin	65	90
	75	75
	85	45
Quince	65	90
	75	75
	85	45
Apple	65	60
	75	40
	85	20

Source	Method	Duration (Minutes)	Product
Oner & Walker (2008)	Steamed	3	Apple
Nigel Slater (2009)	Steamed	15-25	Quince
Jones Family Farms (2021)	Steamed	15-30	Pumpkin

Table 4 Traditional cooking method (Method/duration)

Product	Duration(minutes)
Pumpkin	10
Quince	15
Apple	5

3.3. Preparation and Cooking of Fruits

The apple, quince and pumpkin samples used in the study were peeled and then cut into equal slices, each 5 mm thick, using a Jet's Home mandolin slicer (China). Apple and quince samples were ring-shaped, while pumpkin samples were rectangular.

Figure 2 Preparation of fruits

For the sous-vide cooking process, the sliced fruits and vegetables were placed in special vacuum bags manufactured by Vestel and then vacuumed with a Henkelman Vacuum Systems device (Netherlands). The vacuumization process ensured the optimal vacuum level required for cooking foodstuffs in an airtight environment.

Figure 3 Vacuuming the fruits and making them ready for cooking

The vacuumed apple, quince and pumpkin slices were subjected to sous-vide cooking according to the specified temperature and time conditions. After the cooking process was completed, the products were removed from the cooking process, brought to room temperature and then placed in cold storage at +4°C. The products were kept in cold storage for 24 hours.

Figure 4 Cooking the fruits according to the sous-vide method

Within the scope of the traditional cooking method, apple, quince and pumpkin slices, which were pretreated in the same way as the samples subjected to sous-vide process, were placed on the steaming basket and cooked in boiling water vapor environment in accordance with the specified temperature and time combinations. The cooked samples were kept until they reached room temperature and then the relevant analyzes were carried out.

Figure 5 Traditional cooking of fruits

Color, texture, moisture and sensory analyses were performed on the samples taken from the cold storage.

In order to determine the storage stability, after the cooking process, the products cooked by sous-vide method were stored at -18 °C without opening the vacuum bags and the products cooked by traditional method were placed in refrigerator type food storage bags and stored in deep freezer at -18 °C for 15 and 30 days.

At the end of the storage period, all samples were taken to cold temperatures to be thawed at +4 °C before evaluation and analyzed after the thawing process.

Figure 6 Fruits after cooking with sous-vide

Figure 7 Fruits after traditional cooking

3.4. Analyses

3.4.1 Color Analysis

Color measurements were made using a Minolta CR-400 chromameter. The device measures L* (light-dark), a* (red-green) and b* (yellow-blue) parameters according to the CIELab system. Each sample was measured at 3 different sites and the average value was calculated. This method complies with the color determination standards defined by AOAC (AOAC, 2000). The preservation of color stability in sous-vide treated samples is an important indicator of the advantages of this method (Stea et al., 2007).

Figure 8 Color Analysis with Minolta CR-400 Chromameter

3.4.2 Texture Analysis

Textural properties were evaluated by performing a penetration test with the TA-XT2i Texture Analyzer. Each sample was crushed to 30% strain using a 25 mm diameter probe (Stable Microsystems P/25) moving at 1 mm/s and the maximum force value was recorded in Newton (N). This analysis was used to objectively assess the softening or hardness of the fruits after cooking. Tissue analysis is critical data to support sensory tests for fruits (Silva et al., 2019).

Figure 9 Texture Analysis with TA-XT2i Texture Analyzer

3.4.3 Sensory Analysis

Sensory evaluation was performed by 10 semi-trained panelists using a 9-point hedonic scale (1: Not at all like - 9: Very much like). Panelists evaluated the samples in terms of color, odor, taste, appearance, texture and overall liking. The samples were presented to the panelists in coded randomized order. Sensory analysis was carried out in accordance with ISO 13299 (2016) standard.

Figure 10 Sensory Analysis

3.4.4 Moisture Analysis

The moisture content of the fruit samples was determined according to AOAC 950.46 B(a). Approximately 5 grams of the sample was kept in a drying oven at 105 °C until it reached constant weight. Pre- and post-weighings were made and the moisture percentage was calculated. This method is widely used in the evaluation of shelf life and texture characteristics of processed products.

Calculation: Moisture % = [moisture weight (g) / sample weight (g)] x 100

Figure 11 Moisture Analysis

3.4.5 Cooking Loss and Yield Calculation

Cooking efficiency was calculated by comparing the weights of the products before and after cooking. Yield (%) = (Cooked weight / Raw weight) x 100; accordingly, loss rates were also determined. This analysis reveals the volume loss and water holding capacity of the product by cooking (Baldwin, 2012).

$$\% \text{Cooking Loss} = [100 \times (W_b - W_a) / W_b]$$

$$\% \text{Cooking Efficiency} = [100 \times (W_a / W_b)]$$

W_b: Weight of the sample before cooking (g)

W_a: Weight of the sample after cooking(g)

3.4.6 Storage Stability Analyses

Sous-vide cooked samples were stored frozen at -18 °C for 30 days. On days 0, 15 and 30, color, moisture and sensory analyses were repeated and quality parameters were monitored. Storage stability in frozen foods is important to determine the durability of the product in ready-to-eat form (Church & Parsons, 2000).

FINDINGS AND INTERPRETATION

4.1. Pumpkin Results and Interpretation

4.1.1. Pumpkin Color Analysis

In the samples cooked at 75 °C for 75 minutes, L* value was 47.87, a* value was 27.59 and b* value was 50.37. The decrease in L* value in this group indicates that the color darkened a little and the decrease in b* value indicates that the yellow tones weakened. However, the a* value remained constant, indicating that the red tones could be preserved.

At 85 °C for 45 minutes, L* value was 53.11, a* value was 27.25 and b* value was 59.96. These values indicate that shorter sous-vide cooking at high temperature is more advantageous than the 75 °C group in terms of lightness (L*), and the yellow-orange pigments are better preserved due to the higher b* value.

In the samples steamed with the traditional method, L* value was 48.63, a* value was 23.95 and b* value was 39.63. Both L* and b* values were lower in the traditional method compared to the sous-vide groups, indicating that pigment loss and color darkening were more pronounced in this method.

Table 5 Pumpkin Color Analysis Results

Balkabağı	Çiğ			65C 90 Dakika			75C 75 Dakika			85C 45 Dakika			Geleneksel		
	L	a	b	L	a	b	L	a	b	L	a	b	L	a	b
Pisirme Sonrası	65,01±2,11	35,8±2,47	68,20±1,12	51,01±1,12	27,34±2,06	54,76±2,28	47,87±1,48	27,58±2,96	50,37±1,67	53,11±2,83	27,24±1,05	59,96±2,02	48,62±1,18	23,94±1,53	39,63±1,27
15. Gün	-	-	-	51,49±2,91	27,36±2,63	54,56±1,89	52,35±1,48	27,13±1,23	56,59±2,39	53,97±1,94	26,23±2,77	59,10±1,86	54,89±2,69	26,49±2,43	46,37±2,96
30. Gün	-	-	-	51,02±1,76	27,14±1,34	53,22±2,72	52,55±2,11	26,62±2,54	55,84±1,58	51,32±2,2	25,94±1,41	54,34±2,35	-	-	-

Significant changes were observed in the color parameters as a result of sous-vide cooking. L* value was 51.01, a* value was 27.35 and b* value was 54.77 in the samples cooked at 65 °C for 90 minutes. This indicates that prolonged sous-vide cooking at low temperature is moderately effective in maintaining the lightness and vivid color of the product.

The results obtained reveal that sous-vide method is more advantageous than traditional steaming in preserving color parameters. In particular, 85 °C/45 min application shows that it preserves the brightness and characteristic orange color of the product more effectively with both high L* and high b* values. These findings support that the sous-vide method provides controlled heat treatment in the presence of low oxygen, which makes the color pigments (carotenoids) more resistant to thermal degradation. In the conventional method, direct contact of water vapor and high temperature led to the degradation of color compounds and negatively affected the color values.

In conclusion, this study shows that the sous-vide method gives optimal results in terms of color parameters, especially at medium-high temperature combinations (85°C/45 min), thus contributing to the preservation of the sensory and marketable qualities of the product.

At the end of the 15th day, L* value was 51.50, a* value was 27.36 and b* value was 24.56 in the sous-vide method at 65°C/90 minutes. At the end of 30th day, L* value was 51,02, a* value was 27,14 and b* value was 53,22. These results show that the L* value remained relatively constant during storage in the combination of low temperature and prolonged cooking; however, the b* value decreased to a low level in the first 15 days and showed an increasing trend at the end of the 30th day. This can be explained by moisture redistribution on the product surface and fluctuations in pigment stability during storage.

In the samples cooked at 75°C/75 minutes, L* value was 52.36, a* value was 27.13 and b* value was 56.59 on the 15th day; L* value was 52.55, a* value was 26.62 and b* value was 55.84 at the end of the 30th day. These values support the potential of this temperature combination to maintain storage stability in terms of color parameters. In 85°C/45 min cooking treatment, L* value was 53.97, a* value was 26.24 and b* value was 59.11 on the 15th day. At the end of 30th day, L* value was 51.32, a* value was 25.94 and b* value was 54.34. These results show that high temperature treatment was effective in maintaining the color values at the beginning, but as the storage period progressed, some decrease was observed in L* and b* values.

In the traditional method, L* value was 54.90, a* value was 28.49 and b* value was 46.37 at the end of the 15th day. However, color analysis could not be performed after 30 days of storage due to the deterioration of the structural integrity of the samples. The findings revealed that the sous-vide cooking method, especially the 75°C/75 min combination, gave the most successful results in maintaining color stability for a long time. This temperature and time combination is noteworthy for both the preservation of initial color parameters and minimal fluctuations in L*, a* and b* values during 30 days of storage.

On the other hand, it was determined that the color parameters of the products could be maintained within the first 15 days in the traditional steaming method, but it was not suitable for long-term storage due to the structural weakness of the product texture. This finding indicates that the sous-vide method provides a significant advantage over the conventional method in maintaining color stability.

4.1.2. Pumpkin Sensory Analysis (Taste, Odor, Appearance, Texture, General Taste)

Table 6 Pumpkin Sensory Analysis Results

Example	Color	Odor	Taste	Appearance	Texture			General Admissibility
					Fragility	Brittleness	Hardness	
65C 60 Minutes	3,13±1	5,13±1	5,75±0,75	4,63±1	5,5±0,5	4,88±0,5	5,5±0,5	5,13±0,75
75C 40 Minutes	6,25±0,5	6±1	5,5±0,25	5,75±0,25	5,13±0,25	5,63±0,5	4,75±0,5	6±0,5
85C 20 Minutes	7,75±0,5	5,5±0,5	5,25±0,25	7,25±0,5	5,63±0,25	6±0,5	6,13±0,5	6,13±0,5

The color score of the 65°C/90 min sous-vide sample was 8.38, odor 7.38, taste 6.00 and appearance 7.88. In terms of textural properties, breakability scored 6.13, crispness 6.88, hardness 7.00 and general acceptability 6.13. These results show that the product scored high in terms of color and appearance and textural hardness was preserved under low temperature and prolonged cooking conditions. However, the relatively low taste parameter indicates that aroma development was limited at low temperature.

Color score was 8.50, odor 7.25, taste 7.25 and appearance 8.00 at 75°C/75 min cooking. In texture, breakability was 5.25, crispness 5.25, hardness 4.75, and the overall acceptability score was 7.13. While this group reached the highest values in terms of color and appearance, taste and odor scores also showed a balanced increase. The decrease in hardness and crispness values indicates that texture softening is sensory preferred at this temperature-duration combination. This is also supported by the highest overall acceptability score.

The color score was 8.38, odor 6.63, taste 6.63, appearance 7.50, friability 4.13, crispness 3.00, hardness 2.75 and general acceptability 3.38 for the 85°C/45 min samples. These results show that although the color parameter remained high, there was a significant decrease in odor, taste and especially textural properties. The low scores for hardness, brittleness and breakability indicate that high temperature adversely affected the tissue integrity in a short time. Therefore, the overall acceptability score also decreased significantly.

In terms of sensory analysis, the findings revealed that 75°C/75 min sous-vide treatment gave optimum results in color, appearance, taste and odor parameters. The medium temperature and time combination promoted the development of aromatic components and prevented over-softening of the texture, resulting in a balanced sensory profile.

Low temperature and long cooking time (65°C/90 min) was successful in maintaining textural integrity, but flavor development was limited, resulting in a lower overall acceptability score. High temperature and short cooking (85°C/45 min), on the other hand, preserved color vibrancy, but caused deterioration in textural parameters and decreased consumer appreciation.

As a result, the combination of 75°C/75 min cooking by sous-vide method in pumpkin stands out as the most suitable process that maximizes sensory quality due to color vibrancy, balanced aroma profile and optimum softness.

4.1.3. Pumpkin Moisture Analysis

Table 7 Pumpkin Moisture Analysis Results

Pumpkin	Raw (%)	Traditional (%)	65C 90 Minutes (%)	75C 75 Minutes (%)	85C 45 Minutes (%)
After Baking	93,75±1,63	94,59±1,41	86,15±1,99	86,01±1,17	85,61±1,47
Day 15	-	-	94,66±1,95	93,55±1,85	95,41±1,79
Day 30	-	-	95,44±1,28	95,02±1,84	94,72±1,6

In this study, the moisture contents of raw, sous-vide cooked, stored and traditionally cooked pumpkin samples at different temperatures and times were determined and compared.

The moisture content of raw pumpkin was measured as 93.75%. After cooking with the traditional method, the moisture content increased to 94.59%. It was observed that the moisture content decreased significantly after cooking with sous-vide method. In the samples cooked at 65°C/90 min, the moisture content after cooking was 86.15%, this value was 94.66% at the end of the 15th day of storage and 95.44% at the end of the 30th day.

Similarly, the post-cooking moisture content of 75°C/75 min sous-vide samples was 86.01%, which increased to 93.55% at the end of 15 days of storage and 95.02% at the end of 30 days. In the samples cooked at 85°C/45 minutes, the post-cooking moisture content was 85.61%, 95.41% at the end of the 15th day and 94.72% at the end of the 30th day.

The results show that the sous-vide cooking process initially reduces the moisture content of the product, but during the storage process, the bound water in the product structure can be released and redistributed on the surface or in the analysis sample. This can be explained by the moisture increase observed on days 15 and 30. The fact that the moisture content was even higher than the initial value during the storage process may be related to the fact that the water released from the cell walls after cooking could not pass to the external environment and was retained in the bag and included in the measurement during the analysis.

The increase in moisture content after cooking in the traditional method can be explained by the direct contact of water in the vapor environment and the penetration of water on the product surface. However, in the sous-vide technique, moisture loss during cooking is controlled due to the effect of the vacuum closed system, which allows the moisture balance to be restored in storage while maintaining the targeted structural properties of the product after cooking.

These findings suggest that the sous-vide method optimizes water holding capacity, which is particularly associated with sensory parameters such as texture softness and mouthfeel. The low moisture content after cooking provides a denser texture, while the redistribution of moisture during storage contributes to maintaining the fresh feel of the product throughout its shelf life.

4.1.4. Pumpkin Cooking Loss and Yield

Table 8 Pumpkin Cooking Loss Yield Results

Pumpkin	(%)	Traditional	65C 90 Minutes	75C 75 Minutes	85C 45 Minutes
After Baking	Missing	11,24	5,00	3,59	5,63
	Yield	88,76	95,00	96,41	94,38
Day 15	Missing	-	5,64	6,84	6,93
	Yield	-	94,35	93,16	93,07
Day 30	Missing	-	6,91	9,47	8,46
	Yield	-	93,09	90,53	91,54

In this study, cooking loss and yield values of pumpkin samples cooked raw, cooked by sous-vide method at different temperatures and times, subjected to storage process and cooked by traditional method were determined and evaluated comparatively.

The post-cooking loss rate of the samples cooked with the traditional method was 11.24% and the yield was 88.76%. In the sous-vide method, lower loss and higher yield values were

obtained initially. In 65°C/90 min sous-vide application, loss after cooking was 5.00% and yield was 95.00%. In the storage process, the loss increased to 5.64% and yield was 94.35% at the end of the 15th day, while the loss was 6.91% and yield was 93.09% at the end of the 30th day.

In 75°C/75 min sous-vide samples, loss after cooking was 3.59% and yield was 96.41%, loss at the end of 15th day was 6.84% and yield was 93.16%, loss at the end of 30th day was 9.47% and yield was 90.53%. This group initially showed the lowest loss and the highest yield.

In the samples cooked at 85°C/45 minutes, the loss after cooking was 5.63% and the yield was 94.38%; at the end of the 15th day, the loss was 6.93% and the yield was 93.07%, and at the end of the 30th day, the loss was 8.46% and the yield was 91.54%.

The data obtained show that sous-vide cooking method provides high efficiency by minimizing cooking loss. Especially the 75°C/75 min application stands out with the lowest loss (3.59%) and highest yield (96.41%) values after cooking. This result shows that by applying the optimal time at medium temperature, the cell structure of the product is less disrupted and water loss is kept to a minimum.

When the storage process was analyzed, it was observed that the cooking loss rates in all sous-vide groups partially increased over time and the yield rates decreased accordingly. This may be attributed to microstructural changes in the product texture during storage and increased loss of free water during freeze-thawing. However, the loss rates were still lower compared to the conventional method.

Cooking loss in the conventional method was higher than in the sous-vide groups at 11.24%. This indicates that more water loss occurs during steaming due to direct heat transfer and evaporation from the surface. In addition, since the structure stability is limited during storage in this method, the upward trend of loss rates may be faster.

As a result, the sous-vide cooking method increases efficiency by minimizing cooking loss, especially with 75°C/75 min application; this feature contributes to the preservation of product quality throughout the shelf life.

4.1.5. Pumpkin Texture (Hardness) Analysis

Table 9 Pumpkin Texture Analysis Hardness Results

Batch	Hardness
Balkabağı	N
Çiğ	81,13±2,85
65C 90 Dakika	32,94±1,86
75C 75 Dakika	31,71±1,93
85C 45 Dakika	30,65±2,47
Geleneksel	8,97±2,14
Depolama 15.Gün-65C	14,46±2,26
Depolama 15.Gün-75C	11,55±1,74
Depolama 15.Gün-85C	8,64±2,38
epolama 15.Gün-Geleneksel	1,03±1,88
Depolama 30.Gün-65C	26,58±2,14
Depolama 30.Gün-75C	8,64±2,41
Depolama 30.Gün-85C	8,85±2,08

In this study, the hardness values (in Newton) of pumpkin samples were investigated comparatively in raw, cooked by sous-vide method at different temperatures and times, subjected to storage process and cooked by traditional method.

The hardness value of raw pumpkin was measured as 81.14 N. Hardness values decreased significantly as the temperature increased in the cooking processes performed by sous-vide method. The hardness value of the samples cooked at 65°C/90 min was measured as 82.95 N, which is very close to the raw sample. This indicates that low temperature and prolonged cooking had limited effect on textural softening.

The hardness value was 31.71 N at 75°C/75 min and 30.65 N at 85°C/45 min. These values indicate that textural softening became more pronounced as a result of the breakdown of cell walls and pectin structure due to the increase in temperature.

The hardness value of the samples cooked by the traditional method was 8.97 N, which was considerably lower compared to the sous-vide groups. This indicates that during steaming, the texture of the product softened excessively due to rapid water uptake and excessive heat treatment.

When the storage process was analyzed, fluctuations were observed in the hardness values of the sous-vide samples depending on the storage time. In the 65°C/90 min group, the hardness value was 14.47 N on the 15th day and 26.58 N at the end of the 30th day.

In the 75°C/75 min group, the hardness value showed a downward trend during storage; it decreased to 11.56 N on the 15th day and 8.64 N on the 30th day. This indicates that tissue integrity gradually weakened during the storage process in the medium temperature treatment. A similar trend was observed in the 85°C/45 min treatment, and the hardness value was measured as 8.65 N on day 15 and 8.85 N on day 30. The fact that the hardness value remained relatively constant in this group may be attributed to the fact that the high temperature initially softened the tissue sufficiently and did not cause additional thawing during the storage process.

In the traditional method, the hardness value on the 15th day was determined as 1.04 N. This value indicates that the steaming process breaks down the product texture in the fastest way and almost completely loses its hardness during the storage process.

The results show that the samples cooked at low temperature (65°C/90 min) by sous-vide method initially retain their hard texture to a great extent; however, they show partial softening with structural change during the storage period. In the medium temperature (75°C/75 min) and high temperature (85°C/45 min) applications, significant softening was achieved during cooking, while hardness values remained constant or decreased during storage. This shows that the sous-vide method offers a flexible technology to achieve the desired texture targets with different temperature combinations.

The traditional cooking method, on the other hand, caused rapid dissolution of the product texture due to excessive water uptake and heat effect at the beginning; the low hardness values indicate that the textural integrity could not be maintained during the storage process. This finding suggests that the sous-vide method offers mouthfeel in line with consumer expectations

by managing textural quality in a controlled manner and provides a more stable structure throughout the shelf life compared to the conventional method.

4.2. Analysis Results Of Quince

4.2.1. Quince Color Analysis (L, a, b)

Table 10 Quince Color Analysis Results

	Çiğ			65C 90 Dakika			75C 75 Dakika			85C 45 Dakika			Geleneksel		
Ayva	L	a	b	L	a	b	L	a	b	L	a	b	L	a	b
Pisirme Sonrası	82,3±2,47	1,49±1,15	27,99±2,89	61,34±1,72	(-0,34)±1,17	21,95±2,28	67,06±1,48	(-0,465)±2,54	25,34±1,58	68,01±2,2	0,79±1,41	30,07±2,35	63,69±1,53	1,78±1,71	26,42±1,11
15. Gün	-	-	-	46,27±2,05	10,16±2,63	29,58±1,83	65,98±2,91	3,7±1,67	30,92±2,77	66,32±1,05	2,79±2,02	32,33±1,18	63,23±2,11	2,30±1,27	22,04±1,37
30. Gün	-	-	-	63,27±1,96	3,36±1,34	28,36±2,14	61,75±1,23	3,65±2,39	29,95±1,94	66,3±2,68	2,32±1,86	33,04±2,8	-	-	-

In raw quince, L* value was 82.31, a* value was 1.49 and b* value was 27.99. These values indicate that raw quince has naturally low luminosity (L*) and b* value reflects yellow tones.

After cooking at 65°C/90 minutes using sous-vide method, L* value was 61.34, a* value was -0.34 and b* value was 21.95. The significant increase in the L* value indicates that the lightness value of the fruit increased significantly after cooking. The negative a* value indicates a slight greenish shift in the color tone, while the decrease in the b* value indicates that the yellow tones weakened slightly.

In 75°C/75 min sous-vide samples, L* value was 67.06, a* value was -0.47, b* value was 25.34. This group had one of the highest L* values and was one of the brightest samples in terms of lightness. The b* value remained higher than the other temperatures, indicating the preservation of yellow tones.

In the 85°C/45 min sous-vide group, L* value was 68.01, a* value was 0.79 and b* value was 30.07. This group showed the highest L* and b* values. The positive a* value indicates that the slightly reddish tone was restored at this temperature.

In the samples processed with the traditional cooking method, L* value was 63.69, a* value was 1.78 and b* value was 26.42. While the lightness (L*) and b* values in the traditional method remained moderate compared to the sous-vide groups, the positive a* value indicates that the red tones were prominent.

According to the storage analysis, L* value was 46.27, a* value was 10.16, b* value was 29.58 on the 15th day; L* value was 63.27, a* value was 3.36, b* value was 28.36 on the 30th day in 65°C/90 min sous-vide samples.

In 75°C/75 min samples, L* value was 65.98, a* value was 3.70, b* value was 30.92 on the 15th day; L* value was 61.75, a* value was 3.65, b* value was 29.95 on the 30th day. This group showed a controlled decrease in L* value and constancy in a* value during storage. The stable b* value indicates that the yellow tones were preserved.

In the 85°C/45 min group, L* value on the 15th day was 66.32, a* value 2.79, b* value 32.33; L* value on the 30th day was 66.30, a* value 2.32, b* value 33.04. These data show that the samples cooked at high temperature maintained the most stable color parameters during storage.

In the traditional cooking method, L* value was determined as 63.23, a* value as 2.30, b* value as 22.04 after 15 days of storage. The fact that the b* value, which reflects the yellow tones, was lower than the sous-vide groups shows that the traditional method has a limited effect on the preservation of yellow pigments.

In quince samples, sous-vide method preserved the color parameters in the best way in terms of lightness (L) and yellow tones (b)**, especially in high temperature (85°C/45 min) treatment. The stability of the color parameters in the 85°C group during the storage period reveals that the sous-vide technique can protect the color pigments against oxidative degradation thanks to the controlled cooking conditions.

In the low temperature (65°C/90 min) group, a sharp increase in a* value was observed in the first 15 days of storage, indicating that the color tone shifted to red and may be related to the oxidative transformation of polyphenol compounds. At the end of 30 days, L* value increased and a* value decreased, indicating that the color tone partially returned.

In the traditional method, the yellow tones (b*) remained significantly lower, supporting the fact that this method increases pigment losses. These results show that the sous-vide method offers a significant advantage over the traditional method in terms of both preserving color pigments and ensuring color stability during storage.

4.2.2. Quince Sensory Analysis (Taste, Odor, Appearance, Texture, General Taste)

Table 11 Quince Sensory Analysis Results

Örnek	Renk	Koku	Tat	Görünüş	Tekstür			Genel Kabul Edilebilirlik
					Kırılabilirlik	Gevreklik	Sertlik	
65C 90 Dakika	5,63±0,5	7,63±0,5	7,25±0,5	6,5±0,5	6,75±0,5	6,63±0,75	6,5±0,5	6,63±1
75C 75 Dakika	7,88±0,75	7,63±0,5	7,63±0,5	8,25±0,5	6,63±0,5	7,5±0,5	7,13±0,5	7,88±0,5
85C 45 Dakika	7,75±0,5	7,63±0,5	8,13±0,25	7,5±0,5	7±0,25	6,38±0,25	6,25±0,25	7,5±0,25

The color score was 5.63, odor was 7.63, taste was 7.25, and appearance was 6.50 for the samples treated at 65°C/90 min. In terms of textural properties, friability was 6.75, friability 6.63, hardness 6.50, and the general acceptability score was 6.63. While this group scored positively especially in odor and taste parameters, the relatively low color and appearance scores indicate that the natural color development of quince was limited during the low temperature cooking process. Textural properties remained stable, indicating that this temperature-duration combination was sufficient to maintain textural stability.

The color score of quince samples cooked at 75°C/75 min was 7.88, odor 7.63, taste 7.63 and appearance 8.25. Texturally, friability was scored 6.63, crispness 7.50, hardness 7.13, and the general acceptability value was 7.88. This group showed balanced and high scores in all parameters. Especially the high color and appearance scores prove that the medium temperature cooking condition provides both the desired color formation and an attractive appearance in

quince. The high texture scores also indicate that the panelists considered this temperature-duration combination to be the most ideal condition in terms of texture.

In the 85°C/45 min sous-vide group, the color score was 7.75, odor 7.63, taste 8.13, appearance 7.50, breakability 7.00, crispness 6.38, hardness 6.25 and general acceptability 7.50. These results show that high temperature treatment maximized the taste parameter. However, the hardness and crispness values decreased slightly, suggesting that the combination of high temperature and short time slightly over-softened the quince texture and slightly negatively affected the mouthfeel.

Sensory evaluation of the quince samples showed that the 75°C/75 min sous-vide cooking treatment gave optimum results with the highest score in terms of overall acceptability. This combination of temperature and time especially supported color formation and appearance, while contributing to the balanced development of aromatic components. Textural scores were also high, indicating that panelists found the samples cooked at medium temperature more satisfying in terms of both textural integrity and mouthfeel.

The limited color score in the low temperature (65°C/90 min) treatment indicates that the characteristic color transformation of quince (e.g. polyphenols to red tones) was not fully achieved. On the other hand, taste and odor scores prove that the natural aromatic properties of quince can be preserved even when cooked at low temperature.

In the high temperature (85°C/45 min) treatment, the taste parameter reached the highest value; this may be attributed to the rapid extraction of aromatic components and the development of sugar caramelization in a short time. However, textural parameters slightly decreased in this group, indicating that high temperature weakened the structural integrity to some extent.

As a result, 75°C/75 min sous-vide cooking of quince provided optimum sensory quality in terms of both color-appearance and taste-odor balance and was highly appreciated by the panelists.

4.2.3. Quince Moisture Analysis

Table 12 Quince Moisture Determination Results

Quince	Raw (%)	Traditional (%)	65C 90 Minutes (%)	75C 75 Minutes (%)	85C 45 Minutes (%)
After Baking	83,87±1,43	83,61±1,12	83,62±1,04	82,94±1,28	83,43±1,57
Day 15	-	-	95,77±0,45	94,94±0,57	96,21±0,42
Day 30	-	-	96,32±0,35	95,84±0,25	95,33±0,19

The moisture content of raw quince was measured as 83.87%. After cooking with the traditional method, this ratio was found to be 83.61%. The moisture content of the sous-vide method samples after cooking remained close to the raw sample. The moisture content was 83.62% after 65°C/90 min sous-vide cooking, 82.94% at 75°C/75 min and 83.43% at 85°C/45 min. These findings show that the sous-vide method provides controlled cooking in a closed environment, thus limiting the sudden moisture loss of the product during cooking.

When the storage process was analyzed, the moisture content of the samples cooked at 65°C/90 minutes reached 95.77% at the end of the 15th day and 96.32% at the end of the 30th day. Similarly, in the 75°C/75 min group, the moisture content was 94.94% on the 15th day and 95.84% on the 30th day; in the 85°C/45 min application, it was 96.21% on the 15th day and 95.33% on the 30th day.

The findings indicate that the moisture content of quince samples cooked by sous-vide method remained close to the initial values after cooking and increased significantly during storage.

The continued increase in moisture content as the storage period progressed was more pronounced especially in the samples cooked at low temperature (65°C). This suggests that the low temperature treatment allowed water to be retained more effectively during storage due to less damage to the cell walls.

In the samples cooked in the traditional method, the moisture content after cooking was very close to that of the raw sample, but it could not be clearly examined whether this method preserved the product structure during storage. This finding indicates that the closed vacuum environment obtained by sous-vide method optimizes the water holding capacity and contributes to moisture stability by protecting the product from external factors during storage.

4.2.4. Quince Cooking Loss and Yield

Table 13 Quince Cooking Loss Yield Results

Quince		Traditional (%)	65C 90 Minutes (%)	75C 75 Minutes (%)	85C 45 Minutes (%)
After Baking	Missing	21,29	13,00	9,25	7,64
	Yield	78,70	87,00	90,75	92,36
Day 15	Missing	-	18,75	16,28	14,04
	Yield	-	81,25	83,72	85,96
Day 30	Missing	-	19,03	9,05	10,05
	Yield	-	89,87	90,95	89,95

In quince samples processed with the traditional cooking method, the loss rate after cooking was 21.29% and the yield rate was 78.70%. This value shows that water loss is significantly high in the traditional method and causes a significant decrease in product weight.

It was observed that the loss rates were significantly lower in the samples cooked by sous-vide method. In the 65°C/90 min sous-vide group, loss after cooking was 13.00% and yield was 87.00%. In the storage process, loss was 18.75% and yield was 81.25% at the end of the 15th day; loss was 19.03% and yield was 80.97% at the end of the 30th day. These results show that water release continues during storage at low temperature treatment.

In 75°C/75 min sous-vide application, the loss rate after cooking was 9.25% and yield was 90.75%. At the end of the 15th day, the loss was 16.28% and the yield was 83.72%; at the end of the 30th day, the loss was 9.05% and the yield was 90.95%. While this group had the most balanced loss-yield balance after cooking, it is noteworthy that the yield rate increased again at

the end of the 30th day. This may be explained by the stabilization of intra-tissue water redistribution during storage.

In the 85°C/45 min sous-vide group, loss after cooking was 7.64% and yield was 92.36%. At the end of storage, the loss was 14.04% and the yield was 85.96% on the 15th day and the loss was 10.05% and the yield was 89.95% on the 30th day. This group provided the lowest loss value after cooking; however, some additional loss was experienced in storage due to the effect of high temperature.

The results clearly show that the sous-vide method significantly reduces water loss and increases product yield compared to conventional cooking. The loss rate of over 21% in the traditional method indicates that water is rapidly removed from the tissue due to direct heat and water contact during steaming. In sous-vide applications, on the other hand, the vacuum closed environment keeps the water loss of the product to a minimum and optimizes the cooking efficiency. In particular, 85°C/45 min application provided the lowest loss and highest yield value after cooking. However, it is possible to accelerate textural deterioration and additional losses due to high temperature during storage.

The 75°C/75 min group stands out for its low loss rate after cooking and its stability at the end of storage by increasing the yield value back to a high level. This indicates that this temperature-duration combination provides optimum water retention and tissue preservation conditions for fruits such as quince. In the low temperature (65°C/90 min) group, the loss values after cooking remained relatively high, and the loss rate continued to increase during the storage process, indicating that the water retention ability of the tissue at low temperature was limited in terms of long-term stability. In general, the sous-vide method has significant advantages over the conventional method in terms of both reducing cooking loss and maintaining product weight during storage.

4.2.5. Quince Texture (Hardness) Analysis

Table 14 Quince Texture Analysis Results

Batch	Hardness
Ayva	N
Çiğ	41,1±2,74
65C 90 Dakika	31,23±1,89
75C 75 Dakika	31,93±2,15
85C 45 Dakika	25,58±2,97
Geleneksel	14,58±1,63
Depolama 15.Gün-65C	32,3±2,41
Depolama 15.Gün-75C	27,93±1,78
Depolama 15.Gün-85C	35,37±2,26
Depolama 15.Gün-Geleneksel	20,21±2,88
Depolama 30.Gün-65C	32,63±1,86
Depolama 30.Gün-75C	26,97±2,58
Depolama 30.Gün-85C	29,68±2,47

In this study, the hardness values (in Newton) of quince samples were comparatively analyzed raw, cooked by sous-vide method at different temperatures and times, subjected to storage process and cooked by traditional method.

The hardness value of the raw quince sample was measured as 41.10 N. In the samples cooked by sous-vide method, a decreasing trend was observed in the hardness values after cooking due to the increase in temperature. The hardness value was 31.23 N after 65°C/90 min cooking, 31.93 N at 75°C/75 min and 25.58 N at 85°C/45 min. These findings show that the quince tissue tends to soften as the cooking temperature increases, while low temperature and long cooking time are more effective in maintaining the hardness value.

The hardness value of quince samples cooked by the traditional method was determined as 14.58 N. This value reveals that the traditional method significantly reduces the hardness parameter by softening the product texture faster.

When the storage process was analyzed, it was observed that the hardness value in the 65°C/90 min group reached 32.30 N at the end of the 15th day and 32.63 N at the end of the 30th day. This means a slight increase compared to the hardness value after cooking. This increase can be explained by water redistribution in the tissue during the storage process and tightening of the cell walls as a result of possible water loss.

The hardness value of 75°C/75 min sous-vide samples showed a gradual decrease during storage. At the end of the 15th day, the hardness value was 27.93 N and at the end of the 30th day it was 26.97 N. This group showed a balanced softness after cooking, while the texture continued to gradually dissolve during the storage process.

It is noteworthy that the hardness value was 35.37 N at the end of the 15th day and 29.68 N at the end of the 30th day in the 85°C/45 min treatment. Compared to the post-cooking value (25.58 N), the increase in hardness value on the 15th day can be explained by the redistribution of free water in the tissue and temporary tightening of the cell structure, especially during the storage process. However, the hardness value decreased again at the end of the 30th day.

In the samples processed with the traditional cooking method, the hardness value was 20.21 N at the end of the 15th day. Although this indicates a slight recovery compared to the low hardness value after cooking, it shows that the hardness values remain quite low compared to the sous-vide samples.

The results show that the sous-vide method can control the hardness value of the quince texture and provide a texture that meets consumer expectations. Low temperature and prolonged cooking (65°C/90 min) preserved the textural integrity the most. Medium temperature (75°C/75 min) provided an optimum textural quality with the desired softness and balanced thawing throughout storage.

High temperature (85°C/45 min) treatment produced significant softening during cooking, but showed a temporary tightening of the texture during storage followed by a tendency to soften again.

In the conventional method, the hardness values remained low, indicating that the quince texture disintegrated rapidly and the textural integrity was weaker during shelf life compared to the sous-vide method.

In general, the sous-vide method offers a significant advantage in terms of optimizing textural quality and providing storage stability in products with important structural properties such as quince when the temperature and time parameters are selected correctly.

4.3. Apple Analysis Results

4.3.1. Apple Color Analysis (L, a, b)

Table 15 Apple Color Analysis Results

	Çiğ			65C 60 Dakika			75C 40 Dakika			85C 20 Dakika			Geleneksel		
Elma	L	a	b	L	a	b	L	a	b	L	a	b	L	a	b
Piçirme Sonrası	72,05±2,84	3,18±1,37	32,62±2,16	46,89±1,92	10,72±1,53	28,07±2,48	57,54±2,6	3,24±1,64	28,29±1,31	57,45±2,42	2,76±1,73	32,66±1,09	61,82±2,71	1,91±1,36	33,01±2,84
15. Gün	-	-	-	52,32±1,08	5,63±2,43	27,05±2,33	58,06±2,55	2,73±1,56	28,12±2,43	61,76±1,19	1,64±2,07	35,36±2,46	67,37±2,63	2,99±1,92	37,72±1,82
30. Gün	-	-	-	56,37±2,71	7,44±1,55	28,89±2,01	56,44±1,11	1,14±0,96	28,15±2,88	60,23±2,88	2,17±2,59	30,59±2,5	-	-	-

The color values of raw apple were determined as L* 72.05, a* 3.18, b* 32.62. These values indicate that the apple has a bright surface color with high lightness and distinct yellow tones (b*).

In apple samples cooked by sous-vide method at 65°C/60 min, L* value was 46.89, a* value was 10.72, b* value was 28.07 after cooking. These results show that there was a significant decrease in the lightness value (L*) after cooking, while the a* value increased and the red tones became more pronounced. During the storage process, L* value was 52.32, a* value was 5.63, b* value was 27.05 at the end of 15th day and L* value was 56.37, a* value was 7.44, b* value was 28.09 at the end of 30th day. This shows that the L* value gradually increased and the color lightened during the storage process, while fluctuations were observed in the a* value. This change can be attributed to the oxidative conversion of polyphenols and water redistribution during storage.

In 75°C/40 min sous-vide application, L* value was 57.54, a* value was 3.24 and b* value was 28.29 after cooking. These values show that the a* value is close to the raw product, while the a* value remains high after cooking at medium temperature. At the end of the 15th day of storage, L* value was 58.06, a* value was 2.73, b* value was 28.12; at the end of the 30th day, L* value was 56.44, a* value was 1.14, b* value was 28.15. This group maintained the most stable L*, a* and b* values throughout the storage process.

In 85°C/20 min sous-vide group, L* value was 57.45, a* value was 2.76, b* value was 32.66 after cooking. Short cooking at high temperature maintained the lightness value of the apple at a moderate level, while keeping the b* value very close to the raw sample, preventing the loss of yellow tones. At the end of storage, the 15th day L* value was 61.76, a* value 1.64, b* value 35.36; 30th day L* value 60.23, a* value 2.17, b* value 30.59. This group showed strong performance in terms of color stability by maintaining the b* value at the highest levels throughout storage.

In the traditional cooking method, L* value was 61.82, a* value was 1.91, b* value was 33.01 after cooking, and L* value was 67.37, a* value was 2.99, b* value was 37.72 at the end of 15th day storage. The fact that the L* value remained high after cooking in the traditional method and increased further at the end of storage indicates that this method can be successful in maintaining color lightness. The increase in b* value also indicates that yellow tones are strengthened.

The results show that the sous-vide cooking method is successful in maintaining the color stability of apples at medium temperature and short time combinations (75°C/40 min and 85°C/20 min). The b* value in the 85°C group remained close to the raw sample and showed an increasing trend during storage, indicating that the high temperature contributed to the preservation of yellow pigments without deterioration.

In the low temperature (65°C/60 min) treatment, the L* value decreased significantly after cooking, resulting in darkening of the color.

Cooking with the conventional method gave good results in L* and b* values compared to the sous-vide groups. However, it is seen that sous-vide method provides a more consistent color stability thanks to the controlled cooking environment, especially during storage, L*, a* and b* values can be maintained without sudden fluctuations.

In general, sous-vide method offers optimum results with medium-high temperature and short time combinations in preserving the color quality of apples; this contributes to the preservation of the color parameter, which is an important quality criterion in terms of consumer perception.

4.3.2. Apple Sensory Analysis (Taste, Odor, Appearance, Texture, General Taste)

Table 16 Apple Sensory Analysis Results

Examp le					Texture			General Admissibility
	Color	Odor	Taste	Appeara nce	Fragility	Brittlen ess	Hardne ss	
65C 60 Minutes	3,13±1	5,13±1	5,75±0,75	4,63±1	5,5±0,5	4,88±0,5	5,5±0,5	5,13±0,75
75C 40 Minutes	6,25±0,5	6±1	5,5±0,25	5,75±0,25	5,13±0,25	5,63±0,5	4,75±0,5	6±0,5
85C 20 Minutes	7,75±0,5	5,5±0,5	5,25±0,25	7,25±0,5	5,63±0,25	6±0,5	6,13±0,5	6,13±0,5

In 65°C/60 min sous-vide cooking application, color score was 3.13, odor 5.13, taste 5.75, appearance 4.63. In textural parameters, breakability was 5.50, crispness 4.88, hardness 5.50 and general acceptability was 5.13. This group scored low especially in color and appearance parameters. This can be explained by the limited natural color change of apples during low temperature cooking and the lack of visual appeal. Taste and odor parameters were moderate, while textural characteristics provided a balanced but limited appreciation.

For 75°C/40 min sous-vide samples, the color score was 6.25, odor 6.00, taste 5.50, appearance 5.75, breakability 5.13, crispness 5.63, firmness 4.75 and overall acceptability 6.00. This group showed a significant improvement in color, odor and appearance parameters compared to the

low temperature group. Textural parameters also remained at a balanced level, indicating that the medium temperature treatment gave a more satisfactory result in terms of both visual and mouthfeel.

In the 85°C/20 min sous-vide treatment, the color score was 7.75, odor 5.50, taste 5.25, appearance 7.25, crushability 5.63, crispness 6.00, hardness 6.13 and overall acceptability 6.13. This group received the highest scores, especially in color and appearance criteria, indicating that the visual attractiveness of apples reached the maximum level in the combination of high temperature and short time. Textural scores were also balanced, with firmness and crispness values providing a satisfactory mouthfeel in line with consumer perception. However, odor and taste parameters remained moderate, suggesting that high temperature may lead to partial loss of aromatic components.

The sensory analysis results obtained show that the cooking parameters of apple samples by sous-vide method play a determining role on the sensory quality. The 85°C/20 min treatment was rated the highest by the panelists, especially in terms of color and appearance. This shows that the high temperature allows the color pigments to be activated in a short time and the apples gain a more vivid and bright appearance.

The 75°C/40 min treatment also stood out in terms of overall acceptability score, offering a balanced result with moderate improvement in color, odor and appearance parameters. This group contributed to maintaining the aromatic profile without loss, together with a satisfactory textural structure.

The low color and appearance values in the 65°C/60 min treatment can be attributed to the low temperature and the long time for color reactions to take place. However, taste and odor scores were maintained at a basic level, indicating that the low temperature kept the loss of aromatic components to a minimum. However, the overall acceptability score was limited compared to the other groups.

As a result, high temperature and short time sous-vide treatment of apple samples provides optimum results in terms of color and appearance, while medium temperature and time treatment (75°C/40 min) provides an alternative that supports the overall sensory quality in a balanced way and increases consumer appreciation.

4.3.3. Apple Moisture Analysis

Table 17 Apple Moisture Determination Results

Apple	Raw (%)	Traditional (%)	65C 60 Minutes (%)	75C 40 Minutes (%)	85C 20 Minutes (%)
After Baking	87,33±1,17	85,82±2,11	85,26±1,92	85,56±0,51	84,17±1,32
Day 15	-	-	96,43±0,16	95,28±0,29	93,62±0,6
Day 30	-	-	95,17±0,32	93,56±0,87	94,43±0,56

The moisture content of raw apples was measured as 87.33%. In the samples cooked with the traditional method, the moisture content after cooking was found to be 85.82%. This indicates that moisture loss occurs from the surface of the product during the steaming process.

The post-cooking moisture content of apple samples cooked by sous-vide method was found to be slightly lower compared to raw samples. The post-cooking moisture content was 85.26% in the 65°C/60 min sous-vide group, 85.56% in the 75°C/40 min group and 84.17% in the 85°C/20 min group. These values indicate that the sous-vide method limits water loss in a controlled manner thanks to the closed vacuum environment.

A significant moisture increase was observed in the sous-vide groups during storage. In the 65°C/60 min group, the moisture content was 96.43% at the end of the 15th day and 95.17% at the end of the 30th day. Similarly, in the 75°C/40 min group, it was 95.28% on the 15th day and 93.56% on the 30th day; in the 85°C/20 min group, it was 93.62% on the 15th day and 94.43% on the 30th day.

The data obtained show that the moisture content of apple samples cooked by sous-vide method decreased to a limited extent after cooking compared to the raw product, and this loss was largely recovered during storage. This can be explained by the fact that the water bound in the product tissue during cooking is partially released during cooking and since it cannot be discharged in the vacuum closed environment, it re-collects on the surface during the storage process and creates high values in the measurements.

The fact that the moisture values were even higher in the sous-vide groups on the 15th and 30th days compared to the raw product supports both water redistribution and the effect of vacuum bags in limiting water loss to the external environment. Especially in the low temperature (65°C) group, a high moisture content of 96.43% was measured on the 15th day, suggesting that cell walls are less damaged at low temperature and therefore water can be retained more effectively in the structure during storage.

In the traditional method, the limited moisture content after cooking is related to the rapid loss of water from the surface in the steam environment. In addition, since the traditional method does not provide vacuum protection during storage, it was evaluated that the moisture increase was limited compared to sous-vide samples.

In general, the sous-vide method minimizes water loss after cooking by managing the moisture balance of apples in a controlled manner, while at the same time maintaining a high water activity during storage to maintain the freshness of the product throughout its shelf life.

4.3.4. Apple Cooking Loss and Yield

Table 18 Apple Cooking Loss Yield Results

İma		Geleneksel (%)	65C 60 Dakika (%)	75C 40 Dakika (%)	85C 20 Dakika (%)
Pişirme Sonrası	Kayıp	21,49	16	16,05	14,11
	Verim	78,51	84	83,95	85,89
15. Gün	Kayıp	-	24,69	30,65	22,56
	Verim	-	75,3	69,34	77,24
30. Gün	Kayıp	-	16,98	16,79	10,15
	Verim	-	83,01	83,2	89,85

In apple samples cooked by the traditional method, the loss rate after cooking was 21.49% and the yield rate was 78.51%. This result shows that the traditional steaming method causes a high level of water and weight loss in apple samples.

It was observed that the loss rates remained at lower levels in the samples cooked by sous-vide method. In 65°C/60 min sous-vide application, loss after cooking was 16.00% and yield was 84.00%. In the storage process, loss was 16.69% and yield was 83.30% at the end of the 15th day; loss was 16.98% and yield was 83.01% at the end of the 30th day. These values indicate that apple samples cooked at low temperature can retain a reasonable level of water after cooking, but may experience additional losses during storage.

In the 75°C/40 min sous-vide group, the loss rate after cooking was 16.05% and the yield was 83.95%. In the storage process, loss rate was 16.65% and yield was 83.34% at the end of the 15th day; loss rate was 16.79% and yield was 83.20% at the end of the 30th day. This group remained stable by maintaining the loss-yield balance after cooking and during storage.

In 85°C/20 min sous-vide samples, the loss rate after cooking was 14.11% and yield was 85.89%. At the end of 15th day, the loss rate was 16.56% and yield was 83.24%; at the end of 30th day, the loss rate was 10.15% and yield was 89.85%. This group showed the lowest loss rate after cooking; it was also noteworthy that the loss rate decreased and the yield increased at the end of the 30th day. This can be explained by water redistribution in the vacuum environment during storage and reorganization in the product structure.

The results obtained show that sous-vide cooking method has a significant disadvantage in reducing cooking loss in apple samples compared to the conventional cooking method. The high loss rate in the traditional method can be attributed to the rapid evaporation of most of the water content of the product from the tissue.

In sous-vide applications, cooking in a vacuum environment ensured controlled water loss and maintained high yield values after cooking. In particular, the 85°C/20 min application achieved the lowest loss (14.11%) and highest yield (85.89%) after cooking. This group is noteworthy for the fact that the loss rate decreased to 10.15% at the end of 30 days of storage. This can be attributed to the redistribution of moisture in the product tissue and limitation of weight loss in the vacuum bag.

In the low temperature (65°C) and medium temperature (75°C) sous-vide groups, loss rates were similar after cooking, but losses were stable or slightly increased during storage. Although yield values remained stable in these groups, it was observed that the 85°C group was less advantageous compared to the storage advantage.

In general, the sous-vide method limits the cooking loss of apples and increases the economic value of the product by maintaining yield values more stably during storage compared to the traditional cooking method.

4.3.5. Apple Texture (Hardness) Analysis

Table 19 Apple Texture Analysis Results

Batch	Hardness
Elma	N
Çiğ	77,78±2,47
65C 90 Dakika	35,91±1,89
75C 75 Dakika	37,42±2,62
85C 45 Dakika	41,49±1,55
Geleneksel	6,26±2,74
Depolama 15.Gün-65C	8,07±1,98
Depolama 15.Gün-75C	6,93±2,11
Depolama 15.Gün-85C	11,8±1,73
Depolama 15.Gün-Geleneksel	2,84±0,56
Depolama 30.Gün-65C	5,88±2,86
Depolama 30.Gün-75C	13,21±1,78
Depolama 30.Gün-85C	14,42±1,56

In this study, the hardness values (in Newton) of apple samples were comparatively analyzed raw, cooked by sous-vide method at different temperatures and times, subjected to storage process and cooked by traditional method.

The hardness value of raw apple was measured as 77.78 N. This value reflects the natural textural resistance of the apple in its unprocessed state.

After sous-vide cooking, a temperature-dependent change in hardness values was observed. The hardness value of the samples cooked at 65°C/60 minutes was 35.91 N, 37.42 N at 75°C/40 minutes and 41.49 N at 85°C/20 minutes. These data indicate that the combination of increasing temperature and shortening time limits the textural softening of the apple and contributes to higher hardness retention compared to the raw sample, especially in the 85°C treatment. On the other hand, longer cooking time in 65°C and 75°C treatments increased the texture softening and resulted in lower hardness values.

The hardness value of the samples cooked with the traditional method was measured as 6.26 N, indicating that the steaming method significantly softened the tissue.

When the storage process was analyzed, the hardness value of the 65°C/60 min sous-vide group was 8.07 N on the 15th day and 5.88 N on the 30th day. While this group presented a medium soft texture after cooking, it showed a gradual decrease in hardness value during storage. This may be attributed to water redistribution and cell wall dissolution during storage.

In the 75°C/40 min sous-vide group, the hardness value was measured as **6.93 N** at the end of the 15th day and unexpectedly 13.21 N at the end of the 30th day. At the end of 30 days, the increase in hardness value can be explained by the restoration of moisture balance in the tissue during the storage process in some samples or hardening due to moisture loss on the surface.

In the 85°C/20 min sous-vide group, the 15th day hardness value was 11.80 N and the 30th day hardness value was 14.42 N. While this group kept the texture relatively hard after cooking, it was noteworthy that the hardness value tended to increase during the storage process. This finding indicates that high temperature application provides permanent structural stability in the tissue.

In the traditional method, the hardness value on the 15th day was measured as 2.84 N and this low value proves that the texture of the steamed apple could not maintain its structural integrity during the storage process.

The data obtained show that the sous-vide cooking method can manage the hardness parameter of apples in a controlled manner. In particular, the 85°C/20 min treatment kept the firmness value at a relatively high level by maintaining textural stability both after cooking and during storage. This finding suggests that short-term high temperature treatment can provide the desired mouthfeel without over-softening the cell walls.

Although the 65°C/60 min treatment left the hardness value at a moderate level after cooking, it showed significant softening during storage. This group shows that low temperature alone is not sufficient to preserve the texture; water loss and cell wall disintegration may accelerate, especially during storage.

The 75°C/40 min group stands out with an unexpected increase in hardness value during storage. This suggests that water redistribution in a vacuum environment may lead to hardening on the surface. However, this increase should not turn into an undesirable hardness increase in terms of overall sensory quality.

In the traditional method, on the other hand, the hardness value remained very low after cooking and storage, indicating that this method causes excessive softening of the apple texture, causing the product to lose the desired mouthfeel.

In general, the sous-vide method can optimize the textural quality of apples with appropriate temperature and time parameters, providing a stable structure both for fresh consumption and throughout the shelf life.

DISCUSSION: COMPARISON OF FINDINGS WITH LITERATURE

In this study, the effects of different sous-vide cooking temperatures and times on the quality parameters of apple, quince and pumpkin samples were investigated and the findings were compared and evaluated with the existing literature.

5.1. Pumpkin:

In the study conducted by Ilyasoğlu and Yılmaz (2017), it was stated that the color stability of pumpkin samples remained high with sous-vide cooking, especially cooking at 85-90°C was effective in maintaining texture and color properties. In our study, the preservation of L*, a* and b* values in pumpkin samples in 85°C/45 min application and high color appreciation scores in sensory analysis support this literature result. In addition, Tekin et al. (2018) stated that sous-vide application in pumpkin reduces moisture loss and increases cooking efficiency. In our findings, it was observed that the cooking loss in the sous-vide groups remained in the range of 5-13%, while it was 11.2% in the traditional method.

In general, studies in the literature reveal that sous-vide method is superior to traditional methods in terms of preserving quality, reducing cooking loss, improving color stability and textural properties in fruits and vegetables. The findings of our study support these literature results to a large extent, and the unique values obtained in some parameters (e.g. b* increase in apple at 85°C/20 min) are different enough to contribute to the literature.

5.2. Quince

Najman et al. (2021) reported that phenolic compounds and color pigments can be better preserved in quince samples by sous-vide method. In our findings, the high color parameters (L* and b*) of quince samples, especially in 85°C/45 min application, are in parallel with the results of Najman. In addition, Ortiz-Catalan (2017) reported that the textural properties of quince can be better preserved by sous-vide method; this is supported by the fact that hardness values remained significantly higher in sous-vide groups compared to traditional in our study.

5.3. Apple:

Ghazala et al. (1996) reported that color parameters (especially L* value) remained more stable in sous-vide treated apple samples compared to conventional boiling. Similarly, in our study, L* and b* values of apple samples after sous-vide cooking were preserved at a relatively high level, and especially in the 85°C/20 min treatment, it was observed that the color parameters remained closest to the raw value. This finding is consistent with the results of Ghazala. Furthermore, Ortiz-Catalan et al. (2017) reported that sous-vide technique limits textural softening in apples by preserving the pectin structure. This is in line with the high hardness values observed in the sous-vide groups in our study. The significantly lower hardness value in the traditional method (6.26 N) confirms the softening effect mentioned in the literature.

When the moisture determination results were compared with Baldwin (2012), the findings that sous-vide minimizes moisture loss were supported. Moisture content remained higher in the sous-vide groups after cooking compared to the traditional method, and it was found that

moisture content could be maintained during storage due to vacuum packaging. Creed (1998) and Stea et al. (2007) emphasized that sous-vide applications are effective in reducing cooking loss. In our study, cooking loss remained in the range of 14-16% in sous-vide samples, while it exceeded 21% in the traditional method.

ACKNOWLEDMENTS

To our invaluable advisor Prof. Dr. Şebnem TAVMAN, who never withheld her interest and support from us during our undergraduate education, who has always been our source of inspiration with her academic knowledge and guiding approach, who has made a great contribution to the shaping of our scientific thinking; to our precious Beliz Çakıcı, who has always been with us not only with her academic knowledge but also with her understanding, patient and supportive attitude,

To our beloved family, who believed in us throughout our entire education life, always stood behind us with endless labor and love, and made us feel their support under all circumstances,

The Scientific and Technological Research Council of Turkey (TUBITAK) for the financial support and interest in the project numbered 1139B412303560 and titled "*Application of Sous-vide Process on Selected Fruits and Evaluation of Its Effects on Quality Characteristics*" which is a part of our undergraduate thesis study,

To VESTEL BEYAZ EŞYA SAN. VE TİC. A.Ş. and our valuable industrial consultant, Senior R&D Performance and Energy Specialist İrem BIYIKLI, who enabled us to realize this project and supported us throughout the whole process,

To all our esteemed professors of Ege University Department of Food Engineering, who have contributed to our development by sharing their knowledge and experience with us throughout our undergraduate education and who have always been supportive, and to all our friends who have been with us both academically and socially during the times we spent together, overcoming difficulties together and helping us to keep our motivation always high.

ABSTRACT

This study aimed to investigate the effects of chitosan-coated iron oxide nanoparticles and silver nanoparticles on the morphological traits and secondary metabolites of the ornamental plant snapdragon (*Antirrhinum majus*) under greenhouse conditions. Treatments were arranged in a factorial experiment based on a completely randomized design with four replications, involving four concentration levels (0, 50, 100, and 150 mg/L for silver nanoparticles and μM for chitosan-coated iron oxide nanoparticles). The measured parameters included stem diameter, bud diameter, fresh weight of aerial parts, number of lateral branches, chlorophyll content, total sugars, flavonoids, and antioxidant capacity (DPPH). Analysis of variance revealed that the main effects of nanoparticles on the fresh weight of aerial parts, stem diameter, and number of lateral branches were significant at the 1% probability level, and on bud diameter at the 5% level. The interaction effects of nanoparticles on total sugars, flavonoids, and DPPH were also significant at the 1% level. The highest fresh weight and number of lateral branches were observed in the treatment with 100 μM chitosan-coated iron oxide nanoparticles and 50 mg/L silver nanoparticles, while the highest total sugars, flavonoids, and antioxidant capacity were recorded with 150 mg/L silver nanoparticles and 150 μM chitosan-coated iron oxide nanoparticles. These findings confirm the potential of nanotechnology in enhancing the quality and antioxidant properties of ornamental plants and suggest that future research should focus on optimizing concentrations and evaluating long-term effects.

Keywords: Flavonoids, Snapdragon, Total Sugars, Nanoparticles.

INTRODUCTION

Snapdragon (*Antirrhinum majus*), a perennial plant from the *Scrophulariaceae* family native to the Mediterranean region, is highly valued in the floriculture and ornamental industries due to its colorful flowers and attractive structure. This plant is cultivated as an annual in cold regions and as a biennial in areas with mild winters, with its growing demand in global markets highlighting the need for innovative methods to improve its quality and performance. In recent decades, nanotechnology has emerged as a pioneering field of modern science, opening new horizons in sustainable agriculture. Nanoparticles, with their nanometer-scale size and high surface area, have become key tools for enhancing plant growth, controlling pests, and increasing resistance to environmental stresses. Among these, chitosan-coated iron oxide nanoparticles ($\text{Fe}_3\text{O}_4@\text{Chitosan}$ NPs) and silver nanoparticles (AgNPs) stand out due to their targeted nutrient delivery and strong antimicrobial properties, respectively. The application of nanoparticles as pesticides, protective agents, antimicrobials, and nutritional supplements has revolutionized agriculture. Recent studies (e.g., 2024 research on ornamental plants) have shown that silver nanoparticles at low concentrations (e.g., 60 ppm) can significantly increase

fresh weight, stem length, and anthocyanin production by stimulating antioxidant enzyme activity, particularly in a time-dependent manner (Behzad *et al.*, 2024). Additionally, silver nanoparticles at low concentrations have been found to enhance plant growth and boost the production of secondary metabolites like flavonoids, improving antioxidant properties (Mirzaei, & Kiarostami, 2022), which could benefit snapdragon quality. On the other hand, chitosan-coated iron oxide nanoparticles, due to their biocompatibility and ability to prevent particle aggregation, have wide applications in managing environmental stresses. A study on peppermint (*Mentha piperita*) under drought stress showed that increasing concentrations of chitosan-coated iron oxide nanoparticles improved chlorophyll fluorescence and photosynthetic indices (Giglou *et al.*, 2022). Chitosan, a natural polymer derived from chitin, not only enhances nanoparticle stability but also reduces their potential toxicity, enabling safer use in biological systems. These findings suggest that combining iron and silver nanoparticles with chitosan coating could offer a novel approach to improving snapdragon growth, stress resistance, and its medicinal and ornamental applications. This study examines the synthesis, mechanism of action, and potential of these nanoparticles in enhancing snapdragon performance, with an emphasis on their antimicrobial effects and growth stimulation.

MATERIALS AND METHODS

This research was conducted using snapdragon seeds purchased and cultivated in the greenhouse of the Faculty of Agriculture and Natural Resources, University of Mohaghegh Ardabili. Treatments included two types of nanoparticles; silver nanoparticles and chitosan-coated iron oxide nanoparticles; at four concentration levels: 0 (control), 50, 100, and 150 mg/L for silver nanoparticles, and 0 (control), 50, 100, and 150 μ M for chitosan-coated iron oxide nanoparticles. Treatments were applied via foliar spraying in three growth stages of the plants. Seeds were initially sown in seedling trays and, after germination and reaching the four-leaf stage, transplanted into pots containing a 1:1:1 volumetric mixture of organic matter, sand, and garden soil. The experimental design was a factorial arrangement based on a completely randomized design with four replications. Each experimental unit included a sufficient number of plants to ensure reliable statistical data. To assess treatment effects, morphological and growth parameters were measured. The number of lateral branches was recorded using a counting unit. Stem and bud diameters were determined using a caliper with 0.1 mm precision. Fresh weight of aerial parts was measured with a balance accurate to 0.001 g. Total flavonoid content was assessed using the method of Krizek *et al.* (1998) with a spectrophotometer. For total carbohydrate measurement, 0.2 g of green plant tissue was combined with 10 mL of 95% ethanol in a sealed test tube and heated in a water bath at 80°C for 1 hour. After cooling, 1 mL of the sample was mixed with 1 mL of 5% phenol and 5 mL of 98% sulfuric acid, and absorbance was read at 483 nm using a spectrophotometer.

RESULTS

Analysis of variance indicated that the main effects of the treatments (chitosan-coated iron oxide nanoparticles and silver nanoparticles) were significant, except for bud diameter, which was significant at the 5% probability level. The fresh weight of aerial parts, stem diameter, and number of lateral branches were significant at the 1% level (Table 1).

Table 1. Analysis of Variance of the Effects of Silver Nanoparticles and Chitosan-Coated Iron Oxide Nanoparticles at Different Concentrations on Morphological Traits of Snapdragon

Sources of Variation	DF	Stem Diameter	Aerial Parts Fresh Weight	Lateral Branches Number	Bud Diameter
Chitosan coated IONPs	3	8,76**	1957,51**	24,87**	1,89**
AgNPs	3	1,45**	13,57 ^{ns}	56,70**	0,43**

Error	48	0,003	0,126	8,48
Coefficient of Variation	—	8,06	8,745	7,265

*, **, and ns indicate significance at the 5%, 1%, and non-significant probability levels, respectively.

FRESH WEIGHT OF AERIAL PARTS

The results revealed that chitosan-coated iron oxide nanoparticles at 100 μM and silver nanoparticles at 50 mg/L had a significant effect on the morphological traits of snapdragon. The highest plant height, number of first-order lateral branches, and fresh weight of aerial parts were observed in plants treated with 100 μM chitosan-coated iron oxide nanoparticles and 50 mg/L silver nanoparticles (Figure 1A).

STEM DIAMETER

The results showed a significant effect of chitosan-coated iron oxide nanoparticles on stem diameter. The highest stem diameter was observed in plants treated with 50 μM chitosan-coated iron oxide nanoparticles and 150 mg/L silver nanoparticles, while the lowest was found in untreated control plants (Figure 1B).

Figure 1. Interaction effects of chitosan Coated IONPs and AgNPs on Fresh Weight of Aerial Parts (A) and Stem Diameter (B) of Snapdragon.

BUD DIAMETER

Comparative analysis of morphological traits indicated that chitosan-coated iron oxide nanoparticles and silver nanoparticles had a significant effect on bud diameter. The highest bud diameter was observed in plants treated with 150 mg/L silver nanoparticles and 100 μ M chitosan-coated iron oxide nanoparticles, while the lowest was found in untreated control plants (Figure 2A).

NUMBER OF LATERAL BRANCHES

The analysis of the effects of chitosan-coated iron oxide nanoparticles and silver nanoparticles on the number of lateral branches showed that the highest number was achieved in the treatment with 100 μ M chitosan-coated iron oxide nanoparticles and 50 mg/L silver nanoparticles (Figure 2B).

Figure 2. Interaction effects of chitosan Coated IONPs and AgNPs on Bud Diameter (A) Number of Lateral Branches (B) of Snapdragon.

TOTAL SUGARS

The analysis indicated that total sugar content in snapdragon varied with increasing concentrations of silver nanoparticles and chitosan-coated iron oxide nanoparticles. The lowest value was observed in the control treatment (0 mg/L silver nanoparticles and 0 μ M chitosan-coated iron oxide nanoparticles), while the highest was recorded with 150 mg/L silver nanoparticles and 150 μ M chitosan-coated iron oxide nanoparticles. Intermediate concentrations, such as 50 mg/L silver nanoparticles with 100 μ M chitosan-coated iron oxide nanoparticles, also showed an increase in total sugars (Figure 3A).

FLAVONOIDS

The results showed that flavonoid content in snapdragon was influenced by varying nanoparticle concentrations in treatments. The lowest flavonoid content was observed in the control (0 mg/L silver nanoparticles and 0 μ M chitosan-coated iron oxide nanoparticles), while the highest was achieved with 150 mg/L silver nanoparticles and 150 μ M chitosan-coated iron oxide nanoparticles. Intermediate treatments, such as 50 mg/L silver nanoparticles with 100 μ M chitosan-coated iron oxide nanoparticles, exhibited a significant increase in flavonoids, whereas 150 μ M chitosan-coated iron oxide nanoparticles without silver nanoparticles resulted in a decrease, highlighting the importance of balanced concentrations (Figure 3B).

Figure 3. Interaction effects of chitosan Coated IONPs and AgNPs on Total Sugars (A) Flavonoids (B) of Snapdragon.

DPPH

The comparative analysis of mean data revealed that increasing concentrations of chitosan-coated iron oxide nanoparticles generally enhanced antioxidant capacity. The greatest treatment effect was observed from 0 to 150 μM chitosan-coated iron oxide nanoparticles combined with 50 mg/L silver nanoparticles. Additionally, the interaction of both treatments at 100 μM chitosan-coated iron oxide nanoparticles and 100 mg/L silver nanoparticles yielded the highest antioxidant capacity (Figure 4).

Figure 4. Interaction effects of chitosan Coated IONPs and AgNPs on DPPH.

DISCUSSION

The results of this study demonstrated that the application of chitosan-coated iron oxide nanoparticles and silver nanoparticles can significantly affect the morphological and biochemical traits of snapdragon. These findings align with previous reports on the efficacy of nanoparticles in improving growth characteristics and quality of ornamental plants (Anushi *et al.*, 2023; Behzad *et al.*, 2024). Silver nanoparticles, particularly at low concentrations such as 50 ppm, promoted growth, increased the number of lateral branches, and enhanced the fresh weight of aerial parts, likely due to their role in stimulating antioxidant enzyme activity and reducing oxidative stress (Liu, *et al.*, 2020). These nanoparticles may also influence plant signaling pathways by regulating the expression of growth-related genes (Rasheed *et al.*, 2022). Conversely, chitosan-coated iron oxide nanoparticles, with their biocompatible properties and gradual iron release, particularly at 100 μM , contributed to increased chlorophyll, stem diameter, and fresh weight. This could be attributed to improved iron availability, a key element in chlorophyll synthesis and plant metabolism (Giglou *et al.*, 2022). The chitosan coating enhances absorption and reduces potential nanoparticle toxicity, playing a significant role in their effectiveness (Shi *et al.*, 2020). The significant increase in total sugars and flavonoids in combined treatments with high nanoparticle concentrations indicates their interactive effect on secondary metabolite pathways. Flavonoids, important defensive compounds in plant systems, are influenced by environmental factors and stimulants like nanoparticles, potentially through the activation of phenylpropanoid pathways or increased activity of PAL and CHS enzymes (Selvakesavan *et al.*, 2023). These results are consistent with findings from another study on snapdragon by Pourbeyrami Hir and Sardari (2025), which reported significant improvements in vegetative growth, flower diameter, number of lateral branches, and total phenol content with combined use of chitosan-coated iron oxide and silver nanoparticles at concentrations of 100-150 μM and 50-150 mg/L, respectively. Overall, these findings not only confirm the potential

of nanoparticles in enhancing ornamental plant quality but also open new avenues for sustainable production, reduced chemical fertilizer use, and increased medicinal value of plants. Given the growing adoption of nanotechnology in precision agriculture, future research should focus on targeted, safe, and cost-effective nanoparticle applications.

CONCLUSION

This study demonstrated that the combined application of chitosan-coated iron oxide and silver nanoparticles, particularly at moderate to high concentrations, can effectively improve growth and physiological traits in Snapdragon. These nanoparticles enhanced plant height, branching, and flowering while also increasing chlorophyll fluorescence and phenolic compounds.

These findings support the strategic use of biocompatible nanoparticles in ornamental plant management as a promising approach for boosting performance and resilience, particularly within sustainable and eco-friendly agricultural systems.

ABSTRACT

Lightweight metals, particularly magnesium and aluminum, are of great interest in biomedical, automotive, and aerospace industries due to their low density and high specific strength. However, their limited corrosion resistance and insufficient surface mechanical properties under demanding conditions restrict their applications. Therefore, improving these properties through surface coating techniques is of critical importance. In this study, the adhesion strength of bioceramic coatings on magnesium and aluminum alloys was investigated. The bonding characteristics at the coating–substrate interface were evaluated using pull-off, scratch, and delamination tests, and compared in terms of different surface pre-treatments, coating materials, and processing parameters. The findings indicate that bioceramic coatings not only enhance surface performance but also provide strong adhesion, thereby improving long-term reliability.

Keywords: Magnesium, Aluminum, Bioceramic Coating, Adhesion Strength, Corrosion Resistance

INTRODUCTION

Lightweight metals, particularly magnesium (Mg) and aluminum (Al), are widely used in the biomedical, automotive, and aerospace industries due to their low density and high specific strength (Sivamaran, 2022). These metals enhance energy efficiency and offer design flexibility owing to their weight advantage. However, their limited corrosion resistance and insufficient surface mechanical properties adversely affect their long-term performance and restrict their application areas.

To address these limitations, various surface modification and coating technologies have been developed in recent years. Among them, bioceramic coatings stand out due to their high biocompatibility, wear resistance, and strong bonding potential with the substrate; hydroxyapatite (HAp), tricalcium phosphate (TCP), and zirconia are particularly preferred in implant applications (Sonowal, Gautam, Mambiri, & Depan, 2025).

The success of coatings largely depends on the adhesion strength at the coating–substrate interface; insufficient adhesion may lead to peeling, delamination, and performance degradation (PCI Magazine, 2015; Hong et al., 2024; Cloutier et al., 2016). Since the effectiveness of adhesion mechanisms relies on the combined action of surface energy, mechanical interlocking, and chemical bonding, both the surface preparation method (e.g., sandblasting, anodization, laser texturing) and the applied coating technique (sol-gel, electrophoretic deposition, thermal spraying, etc.) directly determine the adhesion strength achieved at the interface (Bharti, 2018).

In the literature, numerous studies have focused on enhancing the adhesion performance of bioceramic coatings on Mg, Al, and Ti alloys. In particular, the use of intermediate layers (e.g., anodization or plasma electrolytic oxidation) has been shown to improve the adhesion of HAp coatings, while composite coatings containing HAp–chitosan or bioactive glass reduce porosity, prevent crack formation, and provide higher adhesion strength values.

In this context, a systematic investigation of the adhesion strength of bioceramic coatings is of critical importance for improving reliability in both engineering and biomedical applications.

AIM AND SCOPE

The aim of this study is to systematically investigate the factors affecting adhesion strength in bioceramic coatings applied to lightweight metals, particularly magnesium (Mg), aluminum (Al), and titanium (Ti).

The following parameters were evaluated:

- Surface pretreatments: Anodization/MAO, laser texturing, sandblasting, silanization
- Coating materials: Hydroxyapatite (HAp), Ca–P phases (OCP, β -TCP), bioactive glasses, composite coatings
- Coating techniques: Sol-gel, electrophoretic deposition (EPD), hydrothermal method, chemical conversion, pulsed electrodeposition, thermal spraying
- Processing parameters: pH, coating thickness, porosity, heat treatment/densification, use of interlayers (TiO_2 , ZrO_2 , MgF_2)

Adhesion strength data were primarily assessed based on pull-off tests, and the findings were correlated with ISO 13779-4 and ASTM C633/D4541 standards. Results were expressed in MPa whenever possible, considering substrate type, surface preparation, coating method, coating thickness, adhesive used, and failure mode (adhesive/cohesive/mixed).

Within this scope, the study sought to answer the following questions:

- Which pretreatment + coating combinations reliably achieve the ≥ 15 MPa adhesion threshold required for clinical use?
- To what extent do composite or densified coatings (e.g., HAp–chitosan, HAp reinforced with bioactive glass) improve adhesion strength?
- What ranges of processing parameters such as pH, heat treatment, thickness, and porosity yield optimum results?
- How do different testing standards and specimen preparation conditions affect the comparability of data?
- While targeting high adhesion values, how can potential trade-offs with corrosion resistance and biocompatibility be balanced?

The outcomes of this study are summarized as:

- (i) a standards-based data table,
- (ii) recommended adhesion ranges and processing windows for specific substrate–coating–method combinations, and
- (iii) design recommendations for orthopedic/dental as well as automotive/aerospace applications.

MATERIALS AND METHODS

In this study, literature published between 2007 and 2025 was reviewed, and adhesion strength data of bioceramic coatings applied on magnesium (Mg), aluminum (Al), and titanium (Ti) alloys were compiled. The coatings considered include hydroxyapatite (HAp), calcium phosphate phases (OCP, β -TCP), bioactive glasses, and composite systems. The aim is to

comparatively evaluate the adhesion strength values reported in different studies and to reveal common trends.

The article selection criteria were as follows:

- Adhesion strength must be directly reported in MPa or based on ISO/ASTM standardized pull-off testing.
- Substrate alloy, coating method, and processing parameters must be clearly specified.
- Data must be verifiable through full texts or reliable secondary sources (reviews/standards).

For comparability, only pull-off test results are presented in the table, while scratch, indentation, or delamination tests are included only as qualitative supporting information.

According to ISO 13779-2/-4, the clinically accepted adhesion criterion for HAp coatings is an average of ≥ 15 MPa, with no specimen falling below 10 MPa. Values below this threshold are considered insufficient for biomedical use.

The findings obtained from the selected literature are systematically presented in Table 1, which includes substrate type, coating method, processing parameters, and the resulting adhesion strengths.

STANDARDS AND TEST METHODS

The adhesion strength of bioceramic coatings is evaluated using various standardized test methods. In this study, particular attention was given to ISO 13779-4 and ASTM C633/D4541 standards.

ISO 13779-4 (Adhesion test for hydroxyapatite coatings): This standard was developed to determine the adhesion strength of hydroxyapatite (HAp) coatings used in medical implants. It specifies the specimen geometry, counter-part conditions, and adhesive properties in detail. For reliable measurement, the adhesive must exhibit a strength at least 5 MPa higher than the expected adhesion of the coating. In addition, for porous coatings, special precautions are described to prevent adhesive penetration into the interface (ISO, 2018).

ASTM C633 (Pull-off test for thermally sprayed coatings): Widely used to determine the tensile bond strength of ceramic and metallic coatings. However, the measured value reflects not only the coating–substrate interface but also the adhesive, surface preparation, and fixture conditions. Therefore, the influence of the testing setup must always be considered when interpreting results (ASTM International, 2017; Pawlowski, 2008).

ASTM D4541 (Portable adhesion testers): This method enables the measurement of pull-off strength using portable devices. While advantageous in field applications, it involves higher uncertainty and variability compared to laboratory-based ISO or ASTM C633 tests. Inter-laboratory repeatability has been reported to vary between 23–76%, indicating that results should be interpreted cautiously in safety and standard evaluations (Sherwin-Williams, n.d.). Moreover, differences of 25–58% have been observed depending on device type, environmental conditions, and adhesive (DeFelsko Corporation, n.d.). Studies on large-scale pipes also showed that ASTM D4541 exhibits higher standard deviation depending on environmental and technical conditions, potentially leading to uncertainty in applications requiring high precision (Croll, Siripirom, & Keil, 2014).

ISO 4624 (Pull-off test for paints and varnishes): An international standard used to measure the adhesion strength of coatings to substrates. In this test, small metal dollies bonded to the coating are pulled perpendicularly under controlled load until detachment occurs, determining the pull-off strength. The method reveals adhesion or internal cohesion of the coating and is used to evaluate coating performance (ISO, 2023).

The differences among these standards complicate the direct comparison of adhesion values reported in the literature. Therefore, in this study, only results obtained using the same test methods were compared numerically, while other methods were considered as supporting information.

RESULTS

The data obtained from the literature are summarized in Table 1, which systematically presents different substrates, coating types, pretreatments, methods, and test results.

Interlayer usage: In Mg alloys, intermediate layers such as anodization significantly enhance the adhesion strength of HAp coatings. For example, in the AZ31–HAp system produced by the CST method, adhesion strength increased from 6.92 MPa to 14.70 MPa with the addition of an anodization interlayer.

Process conditions: The pH of the coating solution plays a critical role in adhesion. In the AZ31–HAp system, an adhesion strength of 6.7 ± 0.5 MPa was reported at pH = 7.5, while in the WE43–HAp system the optimum value of 8.6 MPa was obtained.

Composite coatings: For Mg alloys, HAp–chitosan coatings produced by aerosol deposition reached 24.6–27.7 MPa, HAp/GO coatings prepared by the MAO/PEO method achieved 40.7 MPa, and HAp–MWCNT reinforced Ti coatings reached 32.9 MPa. In addition, 45S5 bioglass coatings subjected to microwave hybrid heating achieved 25–26 MPa. These findings demonstrate that composite systems provide higher adhesion compared to single-phase coatings.

Conversion coatings: In Mg alloys, Ca–P conversion films exceeded 20 MPa, while MgF_2 conversion coatings achieved the highest value of 43.2 ± 5.1 MPa. These results indicate that chemical compatibility and low solubility strengthen adhesion.

Aluminum alloys: Although ceramic oxide layers obtained by PEO/MAO are not strictly bioceramic, they exhibited very high adhesion strengths in the range of 33–70 MPa. When combined with laser micro-texturing, MAO treatments reached values up to 52 MPa.

Titanium alloys: Sol–gel TiO_2 – SiO_2 coatings showed adhesion strengths of 36.6 MPa, while dental porcelain coatings reached 30.89 MPa. In contrast, porous wollastonite coatings achieved only 8.06 MPa according to ISO 4624, highlighting the importance of coating continuity and interface morphology.

The survey of the literature clearly demonstrates that the clinically accepted adhesion threshold of ≥ 15 MPa for bioceramic coatings is reliably attainable across a wide range of systems. Composite architectures and conversion coatings consistently exceed this limit, while MgF_2 interlayers and TiO_2 – SiO_2 sol–gel coatings exhibit the most remarkable values. The superior adhesion strengths reported for Al alloys underscore their suitability for demanding industrial applications, whereas Ti alloys, with their inherent biocompatibility and sufficient adhesion, remain highly attractive for orthopedic and dental implant applications.

Table 1. Adhesion strength (MPa) of bioceramic coatings on Mg, Al, and Ti alloys

Metal	Alloy	Coating (Bioceramic)	Method / Pretreatment	Adhesion Strength (MPa)	Test / Standard	Reference
Mg	AZ31	HAp	CST + Anodization interlayer	14.70	Pull-off	Ngo, Do Chi, Pham, Pham, & Duong, 2024
Mg	AZ31	HAp	CST, no interlayer	6.92	Pull-off	Ngo et al., 2024
Mg	AZ31	HAp	CST, pH = 7.5	6.7 ± 0.5	Pull-off	Ngo, 2020
Mg	AZ31	OCP	CST, pH $\approx$ 5.5–6.2	≈ 4.2	Pull-off	Zhou, Chen, Xu, Tao, Song, & Zhang, 2021
Mg	AZ31B	Ca–P/oxide (MAO)	Micro-arc oxidation	43.5 ± 0.7	Pull-off	Wen, Zhan, Huang, Xu, Luo, & Xia, 2017
Mg	AZ31B	HA/GO composite (MAO)	One-step (HA/GO added into phosphate electrolyte)	40.7 ± 0.5	Pull-off	Wen et al., 2017
Mg	AZ31	HAp/chitosan	Aerosol deposition	24.6–27.7	Pull-off	Hahn et al., 2011
Mg	Mg alloy	HAp	Ultrasonic aqueous synthesis	18.1 ± 2.2	Pull-off	Sun, Chen, Pan, Wang, & Song, 2019
Mg	Mg alloy	Bioglass 45S5	Press + microwave hybrid heating	25.8 ± 2.6	Pull-off	Shen, Cai, Xu, & Zhang, 2015
Mg	AZ31	Ca–P conversion film	Chemical conversion coating	>20.2	Pull-off	Tan, Wang, Geng, Xi, Qiu, & Yang, 2010
Mg	Pure Mg / AZ31	MgF ₂ –MgHPO ₄ (duplex)	Chemical conversion	13.46	Pull-off	Sathyaraj, Ravichandran, & Sankara Narayanan, 2022
Mg	AZ31B	MgF ₂ conversion coating	Chemical conversion	≥ 43.2	—	Yan, Tan, Zhang, & Yang, 2014
Mg	Mg	β -TCP	Chemical conversion / Thermal spraying	16.1 ± 3.4	Pull-off	Geng, Tan, Jin, Yang, & Yang, 2009
Al	AA series	PEO/MAO (Al ₂ O ₃)	Plasma electrolytic oxidation	70	Pull-off	Zhu, Zhang, Liu, Liu, Wang, & Qiao, 2022
Mg	AZ31	HAp	Pulsed ED vs. conventional ED	16.5 / 11.5	Pull-off	Mohajernia, Mazinani, Javidi, & Javid, 2015

Mg	AZ31	HAp	Sol-gel (dip-coating, sintering at 300–500 °C)	22 (300 °C), 28 (400 °C), 35 (500 °C)	Pull-off (ASTM C633 modified)	Niu, Shi, Wei, Li, & Chen, 2016
Al	5052	Ceramic oxide (Al ₂ O ₃ , MAO/PEO)	Laser micro-texturing + MAO	33–52	Pull-off (tensile)	Fan, Wang, Yin, Huang, Da, Jiang, Cao, Gai, & Zhang, 2023
Al	—	Al ₂ O ₃ (PEO single layer)	PEO, “chain-like” discharge regime	~70	Pull-off (on epoxy)	Zhu et al., 2022
Ti	Pure Ti	TiO ₂ –SiO ₂ (sol-gel)	Sol-gel method, dopant optimization	36.6	Pull-off (not specified)	Mumjitha & Raj, 2015
Ti	Commercially pure Ti	Wollastonite–silicate	Laser cladding + surface porosification	8.06	ISO 4624 (pull-off)	Zhevtun et al., 2020
Ti	Ti (unspecified)	HAp + 1% MWCNT	Sol-gel multilayer coating	32.9	Interfacial shear test	Jaafar, Hecker, Árki, & Joseph, 2020
Ti	Ti-6Al-4V	Dental porcelain	Sandblasting + firing	30.89	—	Dikova, Anchev, Dunchev, Gagov, & Dzhendov, 2022

The data in the table reveal that the adhesion strength of bioceramic coatings varies significantly depending on surface pretreatments and coating types. The addition of an anodization interlayer nearly doubled the adhesion strength, while composite coatings (HAp–chitosan, bioactive glass) achieved values of **≥25 MPa**. MgF₂ conversion coatings provided the highest adhesion, reaching approximately **43 MPa**. For Al alloys, PEO/MAO-based coatings exhibited strong adhesion in the range of **33–70 MPa**, whereas Ti alloys demonstrated high adhesion levels of **30–36 MPa** with sol–gel and dental porcelain coatings.

DISCUSSION

The literature findings indicate that the adhesion strength of bioceramic coatings is largely dependent on interface engineering. Pretreatments such as anodization, plasma electrolytic oxidation (PEO), and laser surface texturing significantly enhance coating–substrate interactions by improving surface wettability and facilitating mechanical interlocking.

Composite coatings (e.g., HAp–chitosan, bioactive glass-reinforced systems) reduce porosity, lower the risk of crack initiation, and provide more balanced load transfer. Such designs have enabled adhesion strengths of **≥25 MPa**.

Conversion coatings (Ca–P, MgF₂) achieve high adhesion due to their chemical compatibility and low solubility. However, excessive coating thickness or uncontrolled internal stresses may lead to peeling and delamination.

When comparing results, the influence of experimental variables such as test method, adhesive selection, and specimen preparation must be considered. Therefore, direct comparison of adhesion values reported in the literature has limited reliability.

Overall, the clinically accepted adhesion threshold of 15 MPa can be achieved in bioceramic coatings. Nevertheless, this value alone is not sufficient; it must be evaluated in conjunction with other critical properties such as corrosion resistance, biocompatibility, and fatigue performance.

CONCLUSION

This study systematically examined the factors influencing the adhesion strength of bioceramic coatings on magnesium (Mg), aluminum (Al), and titanium (Ti) alloys. The findings demonstrate that surface pretreatments, coating techniques, and processing parameters play decisive roles in adhesion performance. With proper interface design and optimized parameters, adhesion strengths of ≥ 15 MPa can be achieved, and in some systems, values far exceeding this threshold have been reported.

Key findings:

- Adhesion strength increases significantly when surface cleanliness, roughness, and chemical compatibility are improved simultaneously.
- Mechanical roughening alone is often insufficient; the use of interlayers (e.g., anodization, MgF_2) markedly enhances adhesion.
- Excessively thick or insufficiently densified coatings raise residual stresses, increasing the risk of delamination.
- Composite and dense coatings (e.g., HAp–chitosan, bioactive glass-reinforced systems) reduce porosity, prevent crack initiation, and provide more stable adhesion.
- Adhesion values reported in the literature are influenced by different test standards and experimental variables; therefore, measurement conditions must always be considered when interpreting results.

Practical recommendations:

- In clinical and engineering applications, adhesion strength should be evaluated together with corrosion resistance, biocompatibility, and fatigue performance.
- Failure mode (adhesive, cohesive, or mixed) should always be reported.
- Whenever possible, cross-validation with different test methods (e.g., pull-off, scratch) should be performed.

Future directions:

- Development of strategies to mitigate thermal expansion mismatch between coating and substrate.
- Advancement of low-temperature coating techniques.

In conclusion, achieving the target adhesion strength in bioceramic coatings is feasible; however, ensuring the reliability of these values requires reproducible testing under standardized conditions.

ABSTRACT

Acute poisoning by organophosphates chlorpyrifos is responsible for heavy mortality worldwide, especially in developing countries with high agricultural potential. These products are responsible for poisoning of varying severity depending on the nature of the compound and feed intake. The present work focuses on the study of the effect of toxicity on cholinesterase activity and some parameters of liver function in male rats "Wistar" gavaged with insecticide «chlorpyrifos ". Adult rats received three months chlorpyrifos by gavage at dose DL50/10. At the end of the experiment blood is recovered to determine the activity of butyrylcholinesterase by the colorimetric method of Ellman, and liver function parameters. The brain is taken for the activity of the brain butyrylcholinesterase and proteins contents. Our results show that chlorpyrifos induces increased levels of transaminase activities and alkaline phosphatase reflecting a malfunction of the liver function. Furthermore, inhibition of blood and brain cholinesterases, with an increase of protein levels in brain reflecting neurotoxicity in rats following exposure to chlorpyrifos. These data suggest that organophosphate insecticide administered at DL50/10 doses induce clinical signs of cholinergic poisoning and concurrently reduce brain and plasma cholinesterase activities in the rat.

Keywords: insecticide, rat, cholinesterase activity, biochemical parameters,

INTRODUCTION

Pesticides, sometimes haphazardly applied in large amounts causing environmental pollution, are a cause for concern. Chlorpyrifos (O, O'-diethyl O-3, 5, 6-trichloro-2-pyridyl phosphorothionate) is an organophosphate insecticide with broad spectrum of action with many uses in urban and agriculture. Despite the restriction on its use, it continues to be one of the most commonly used insecticides (Costa et al., 2006; Mahaboob Khan et al., 2007; Rauh et al., 2011). The latter is responsible for acute cholinergic effects exerted by its active metabolite: chlorpyrifos-oxon inhibits acetylcholinesterase, thereby preventing the hydrolysis of acetylcholine, leading to a massive stimulation of cholinergic receptors (Jintana et al., 2009 Wang et al., 2014). These cholinergic systems are known to be involved in cognitive and behavioural functions that are widely disturbed in Alzheimer's disease (AD). In particular, AD is characterized by a loss of forebrain cholinergic neurons that normally express high levels of acetylcholine (ACh) and acetylcholinesterase (AChE), resulting in the simultaneous depletion of both the neurotransmitter and its hydrolyzing enzyme (Morley et al., 2002; Darvesh et al., 2003; Giacobini, et al., 2004 ; Costa et al 2008 ; Quandt et al., 2010; Siva et al 2013).

Mammals have two main classes of cholinesterases: acetylcholinesterase (AChE, E.C.

3.1.1.7) and butyrylcholinesterase (BuChE, E.C. 3.1.1.8). These distinct enzymes possess differences in their tissue distribution, kinetic properties, specificity for synthetic and natural substrates and selective inhibitors although they are evolutionarily related. In humans, AChE is more abundant in the central nervous system, end plate of skeletal muscle and erythrocytes membranes while BuChE is more abundant in serum (Amitai et al., 1998). BuChE, also called nonspecific cholinesterase or pseudocholinesterase, is able to act on hydrophilic and hydrophobic choline esters. At this moment, the exact physiological function of BuChE is not yet clear (Thiermann et al., 2007). Other systems that could be affected by pesticides intoxication are immune system pancreas, liver and biochemical changes (Neishabouri, et al., 2004; Kalender et al., 2005). The main objective of our study is based on the disruption of the functioning of the nervous system by inhibiting an enzyme essential for its proper functioning: cholinesterase and dysfunction of liver function following exposure to insecticides gavage male rats "Wistar". The parameters to be measured are: transaminases, alkaline phosphatase, and cholinesterase activity. This work is still very partial in the field of pesticide toxicology.

MATERIAL AND METHOD

Chemicals

Chlorpyrifos (O, O 9-diethyl-3, 5, 6-trichloro-2-pyridyl phosphorothioate) 98% pure; CAS Registry Number: 5598-13-0; was purchased from New England Nuclear, Boston Leading Manufacturer and supplier by (INRAA, ALGERIA). The structure of chlorpyrifos is shown in Figure 1.

Figure 1. Structure of chlorpyrifos (O,O-Diethyl-0-(3,5,6-trichloro-2- pyridinyl)-phosphorothioate).

Animal and experimental design

All aspects of the experiment were conducted according to the guidelines provided by the ethical committee of the experimental animal care at Tlemcen University. Twenty male rats (Wistar Albino) were obtained from Animal Resource Centre (Algeria). 10 weeks old, with an average weight of 250 ± 10 g. The rats were exposed to a daily 12 h photoperiod and an ambient temperature of 25 °C. They were fed a standard diet, the water being renewed daily. After the habituation period, the animals were divided into 2 groups of 10 rats each. Treatment of rats was performed by oral gavage (per os) administration in 1 mL at a dose of 13, 5 mg / kg body weight, corresponding to (1/10 DL50) of chlorpyrifos which was diluted in a solution corn oil according to the protocol (Goel et al., 2007). Control rats were treated orally with 1 ml of corn oil only. The feedings are made every other day for three months of experimentation. Body weight and food intake were recorded daily. At the end of the experiment (after three months), each batch of rats were sacrificed by decapitation under CO₂ anesthesia. Blood is collected by puncture of the abdominal aorta. A quantity of blood is collected in heparinized tubes and centrifuged at 3000 rev / min for 15 minutes. Total blood and Plasma are immediately used for

the determination of the activity of butyrylcholinesterase. The plasma is also used for the determination of transaminases (AST, ALT) and alkaline phosphatase (ALP) which are markers of liver function. Brain was excised, cerebellum was separated and brain hemispheres were washed with an HEPES-saline buffer (HSB) and placed in a tray of ice (4 °C) used for the determination of protein and the activity of brain butyrylcholinesterase.

Brain extraction and assay of butyrylcholinesterase activity

Preparation of brain homogenates:

The day of the assay, the brain structures collected and stored in liquid nitrogen as homogenized at 4 °C in 20 volumes of Tris / HCl (50mmol/L, pH 7.4) -sucrose (0,32mol /L) in a glass homogenizer (Kontes Glass , Duall). The homogenate is centrifuged at 1000g for 15 min at 4 °C. After centrifugation, the supernatants are recovered for measurement of the activity of butyrylcholinesterase and the protein content.

Assay of butyrylcholinesterase activity

Butyrylcholinesterase was assayed in plasma and supernatant according to the method of (Ellman et al.,1961) using butyrylthiocholine as substrate (the normal range of BuChE is 1200-1600 U/L, from 23 normal sera analyzed). The reaction mixture consisted of 100mM potassium phosphate buffer pH 7.0, 3mM butyrylthiocholine iodide, 2mM 5, 5" dithio-bis (2-nitrobenzoic acid) reagent and 10µl serum in a volume of 500 µl. After incubation at 37°C for 10 minutes the action was stopped with 500µl 2 mM eserine sulphate and read at 412 nm. Units were calculated from the micromolar extinction coefficient of 13.6×10^{-3} for 5-mercapto-2-nitrobenzoic acid.

Chemical analysis

Enzymatic assays (Kit Spinreact) were utilized for the purpose of measuring the plasma levels of glucose, albumin, total cholesterol, and triglycerides.

As for the renal function, it was assessed through the determination of plasma levels of creatinine, uric acid , and urea in blood (Kit Spinreact).

Regarding the liver function, it was evaluated via the enzymatic activity of transaminases, i.e. Aspartate Aminotransferase (AST), Alanine Aminotransferase (ALT), bilirubin and Alkaline Phosphatase (ALP), and by measuring the total plasma protein level in blood (Kit Spinreact).

Statistical analysis

Results are expressed as means $\pm$ standard deviation (SD). After analyzing the comparison of the average variance is performed by the test ' t ' Student between the two groups of rats (control , experimental) This analysis is performed using the STATISTICA software, version 4.1 (STATSOFT , TULSA , OK) . Differences are considered significant at $P < 0.05$.

RESULTS AND DISCUSSION

Chlorpyrifos is a widely used organophosphate insecticide in agricultural and urban pest control products throughout the world. Like most organophosphate pesticides, chlorpyrifos is a neurotoxin. Animals are killed or paralyzed by exposing to chlorpyrifos due to the irreversible

inhibition of cholinesterase (acetylcholinesterase and butyrylcholinesterase), resulting in the disruption of nervous system. Currently, the measurement of the inhibition of the cholinesterase has become one of the biomarkers most frequently used for detecting exposure to organophosphate compounds (Kwong, 2002; Woods et al., 2002; Siraj et al., 2009; Eamkamon et al., 2012; Dzul-Caamal et al., 2014).

Variations in body weight are frequently used as endpoints in acute toxicity studies in rats, as they can reflect the pathophysiological impact of exposure to a toxic substance. Indeed, notable changes in body weight, such as unusual weight loss or gain, are often early signs of deterioration in the state of health of the animals. In our study, variations in body weight were determined in control and experimental rats and recorded daily at the same time in the morning during the experimental period. Our results demonstrate that after four weeks of exposure to 13.5 mg/kg of chlorpyrifos (corresponding to 1/10 DL₅₀), significant variations in physiological parameters were observed compared to the control group. Control rats showed significant weight gain (+30.87 g), indicating normal growth and metabolic adaptation. In contrast, the chlorpyrifos-treated rats showed minimal weight gain (+2.37 g), suggesting growth inhibition. This stagnation may be linked to disturbances in energy metabolism or reduced food intake induced by the pesticide. The treated group had significantly lower daily food intake (14.60 ± 1.12 g/day) than the control group (20.3 ± 1.20 g/day). This reduction may reflect pesticide-induced anorexia or alterations in neuroendocrine signaling pathways that regulate appetite. Water consumption was also markedly decreased in chlorpyrifos-exposed animals (16.73 ± 4.15 mL/day) compared to the control group (38.14 ± 5.4 mL/day). This decline could indicate disturbances in thirst mechanisms, digestive discomfort, or neurotoxic impairment of central fluid balance regulation (table 1).

In general, alterations in organ mass reflect toxicity following exposure to a harmful substance. The heart, liver, kidneys, spleen, brain, and lungs are among the first organs to be affected by the toxicant-induced metabolic response. In our study, the liver showed a marked increase in its absolute and relative weight (12.07 ± 2.42 g vs. 9.10 ± 0.82 g; 5.85% vs. 3.88%), suggesting early liver injury due to pesticide biotransformation. Similarly, the kidneys showed a moderate increase in their absolute weight (1.40 ± 0.10 g vs. 1.34 ± 0.12 g) and a more pronounced increase in their relative weight (0.78% vs. 0.57%), indicating renal stress related to increased excretory activity or nephrotoxic effects. In contrast, the brain showed a significant reduction in absolute (0.97 ± 0.03 g vs. 2.11 ± 0.12 g) and relative (0.47% vs. 0.90%) weight, reflecting neurotoxic lesions that may involve neuronal loss, delayed brain development, or cholinesterase inhibition-induced atrophy (table 2). Our results are consistent with those of (Araoud et al., 2013; Goel et al 2000; Noaishi et al 2013).

Table 1. Variation in Body Weight (g), Daily Food Intake, and Drinking Water Consumption in Control and Chlorpyrifos-Treated Rats After 4 Weeks of Treatment

	Control	Chlorpyrifos 13.5 mg / kg (LD _{50/10})
Body weight (g)		
- Initial	203.84±12.58	203.84±12.58
- Final	234.71± 27.21	206.21± 18.14
- Weight gain	+ 30.87	+ 2.37
Food intake (g/day/rat)	20.3±1.20	14.60±1.12
Water intake (ml/day/rat)	38.14±5.4	16.73±4.15

Values are presented as means $\pm$ SD. Significant differences between control and experimental rats in each group are indicated by: *P < 0.05

Table 2. Variation in Absolute and Relative Weights (%) of Organs in Male Rats After 4 Weeks of Chlorpyrifos Exposure

Organ (%)	Control	Chlorpyrifos 13.5 mg / kg (1/10 LD50)
<u>Liver</u>		
Absolute Weights	9.10 ± 0.82	12.07 ± 2.42
Relative Weights	3.88± 0.15	5.85± 0.12
<u>Kidneys</u>		
Absolute Weights	1.34± 0.12	1.40± 0.10
Relative Weights	0.57± 0.08	0.78± 0.06
<u>Brain</u>		
Absolute Weights	2.11± 0.12	0.97 ± 0.03
Relative Weights	0.90± 0.02	0.47± 0.02

Values are presented as means ± SD. Significant differences between control and experimental rats in each group are indicated by: *P < 0.05

The biochemical profile of blood is one of the most sensitive parameters for assessing the toxicity of xenobiotics and pesticides in humans and animals; these results can provide important information about the internal environment of the organism. The evaluation of biochemical characteristics of different species has become an important means for understanding normal and pathological processes as well as toxicological impacts (Liu et al., 2013). Insecticides, even in very low concentrations, interfere with basal metabolism (Al-Shinnawy, 2008).

Insecticide exposure induced a decrease in albumin levels in rats. These results are consistent with those of El-Demerdash and Nasr (2014), who revealed a reduction in serum albumin levels in male rats treated with diazinon, another organophosphate insecticide (table 3).

The kidney is a primary target organ for xenobiotic compounds, particularly environmental pollutants, due to its high blood flow and its role in concentrating solutes. This susceptibility renders the kidney vulnerable to a wide range of toxic effects, often involving both tubular and glomerular cells (Mohamed et al., 2003). In our study, rats orally exposed to chlorpyrifos (1/10 LD₅₀) showed increased serum levels of urea, uric acid, and creatinine. Such elevations are considered biomarkers of renal dysfunction and tissue damage induced by this insecticide (table 3).

Regarding the lipid profile, our results showed a significant increase in total cholesterol and triglycerides in rats under the influence of chlorpyrifos. This increase can be attributed to the effect of the permeability of the liver cell membrane by pesticides (Yousef et al., 2006). In addition, hypercholesterolemia may be due to the obstruction of the bile ducts of the liver, which reduces or stops the secretion of cholesterol into the duodenum (Ogutcu et al., 2008) (Table 3).

Our results show that chlorpyrifos induces increased levels of transaminase activities and alkaline phosphatase reflecting a malfunction of the liver function (table 3). The transaminase and alkaline phosphatase enzymes are considered as indicator for tissue damage that is explained by the degree of exposure and the severity of toxic symptoms. The significant increase in transaminase and alkaline phosphatase activities in treated rats may be explained by destructive changes in hepatic cells induced by chlorpyrifos. Despite this specific mode of action, the toxic effects of chlorpyrifos are also manifested by severe liver dysfunction. It has been shown that acute or chronic exposure to this insecticide induced a significant increase in transaminases AST and ALT (Goel et al., 2000; Alavanja et al., 2004).

Table 3 . Plasma Biochemical Parameters in Control and Chlorpyrifos-Treated Rats

Parameter	Control	Chlorpyrifos13.5 mg / kg (1/10 LD50)
AST (UI)	56.62 ± 6.18	96.24 ± 2.02*
ALT (UI)	33.5 ± 1.64	68.89 ± 3.22**
ALP (UI)	93. 60 ± 6.9	114.10 ± 4.2**
Bilirubin (µmol/l)	6.78 ± 0.4	5.01 ± 0.2 *
Albumin (g/dl)	16.24± 0.73	14.24± 0.73*
CT (mmol/ml)	1.22± 0.03	1.98± 0.04*
TG (mmol/ml)	1.12± 0.11	1.76± 0.13*
Creatinine (mol/l)	27.42± 0.61	28.5± 0.51
Urea (mmol/l)	5.32± 0.11	7.05± 0.31*
Uric acid (mmol/l)	78.5± 3.14	80.03± 1.78*

TC: Total cholesterol; TG: Triglyceride; AST: Aspartate-Amino-Transferase; ALT: Alanine-Amino-Transferase; ALP: Alkaline phosphatase. Values are presented as means ± SD. Significant differences between control and experimental rats in each group are indicated by: *P < 0.05.

Our data showed an inhibition of blood and brain cholinesterases, with an increase of protein levels in brain reflecting neurotoxicity in rats following exposure to chlorpyrifos (figure 2). These data suggest that organophosphate insecticide administered at DL50/10 doses induce clinical signs of cholinergic poisoning and concurrently reduce brain and plasma cholinesterase activities in the rat. Chlorpyrifos, like other organophosphates, particularly exerts its action by inhibiting the activity of acetylcholinesterase (Amitai et al., 1998; Shenouda et al., 2009; Dzul-Caamal et al., 2014). Indeed, some pesticides such as lindane, endosulfan, dieldrin and Eldrine may result in inhibition of GABAergic receptors and activation of glutamatergic receptors in neuronal cells of mammals, inducing a hyperexcitability syndrome that can evolve up the occurrence of convulsions this is probably related to neuronal lysis sign of Alzheimer's disease in people exposed to pesticides (Sunol et al 2008; Muller et al., 2014).

These preliminary results confirm the presence of alterations in liver function and inhibition of cholinesterase activity reflecting induced neurotoxicity by the insecticide chlorpyrifos in Wistar rats. The measurement of target enzymes, cholinesterase in the case of organophosphates such as chlorpyrifos would be a valuable tool to determine the actual causes of the enhanced toxicity when organisms are exposed to pesticides in general.

Figure 2. Butyrylcholinesterase activities in blood (A) and plasma (B) in control and experimental rats. Values are presented as means $\pm$ SD. Significant differences between control and experimental rats in each group are indicated by: * $P < 0.05$.

CONCLUSIONS

Chlorpyrifos exerts its action by inhibiting cholinesterase activity and impaired liver function. The commercial availability of this product is worrying, justifying the use of a wide prevention program to inform the public and the authorities of the danger organophosphates.

ABSTRACT

Inflammatory and hemolytic disorders linked to oxidative stress represent an increasing public health challenge, thereby justifying the investigation of natural therapeutic alternatives that are effective, stable, and better tolerated. This study aims to evaluate, *in vitro*, the antioxidant, anti-hemolytic, and anti-inflammatory properties of a combination of *Cinnamomum verum* (cinnamon) and *Curcuma longa* (turmeric), prepared as aqueous (decoction) and methanolic (maceration) extracts, and compared with two reference standards: gallic acid and diclofenac sodium.

Phytochemical screening revealed a marked (+++) presence of tannins, flavonoids, terpenoids, and anthraquinones in the aqueous extract, whereas the methanolic extract exhibited moderate to high (++ to +++) levels of these compounds, except for terpenoids, which were present in lower concentrations. The decoction showed a high total polyphenol content (178.46 ± 21.66 mg GAE/g DW), while the maceration was richer in flavonoids (35.43 ± 1.25 mg QE/g DW).

Anti-hemolytic activity assessed on human erythrocytes demonstrated a stable and dose-dependent inhibition for the decoction (from 74.22% to 85.91% at 500 µg/ml), approaching the efficacy of diclofenac (89.35% at 500 µg/ml). The methanolic extract showed a peak effect at 150 µg/ml (86.17%), followed by a marked decrease at higher concentrations.

Regarding anti-inflammatory activity, measured by the inhibition of protein denaturation, a moderate dose-dependent response was observed: from 31.85% to 57.42% for the decoction, and from 28.73% to 52.38% for the maceration. Diclofenac demonstrated a stronger inhibition of 71.63% at 500 µg/ml. Based on the study results, the cinnamon–turmeric synergy, especially in decoction form, stands out for its dual protective bioactivity, highlighting its potential in the formulation of phytopharmaceuticals targeting oxidative and inflammatory conditions.

Keywords: Cinnamon–turmeric synergy, Antioxidant, Anti-Hemolytic, Anti-Inflammatory activity, *in vitro* study,

INTRODUCTION

Chronic inflammatory diseases and hemolytic disorders pose significant challenges to global public health. Although inflammation is essential for defense and tissue repair, it can become harmful when it escapes physiological regulatory control. This dysregulation can lead to persistent tissue damage driven by either the persistence of pathogens or functional abnormalities of immune cells (Chen et al., 2018).

The conventional treatment for inflammation relies primarily on steroidal (glucocorticoids) and non-steroidal (NSAIDs, such as aspirin) anti-inflammatory drugs. Despite their effectiveness, prolonged use is often limited due to significant side effects (Koshi et al., 2022). This has fueled growing interest in natural alternatives, particularly medicinal plants, which are a valuable source of bioactive compounds that could be used for safer and more effective therapies (Mukhtar et al., 2008).

In toxicological in vitro approaches, erythrocytes are widely used as an experimental model to assess the cytotoxicity of plant extracts. Their abundance, combined with the ease of monitoring hemolysis through hemoglobin release into the extracellular medium, makes erythrocytes a reliable and reproducible system (Ghlichloo, 2023).

Since antiquity, medicinal plants have played a central role in traditional healing practices worldwide. Their abundance of bioactive molecules gives them considerable therapeutic potential, a topic that modern research is increasingly exploring in relation to various pathological conditions, particularly inflammatory and metabolic disorders (Khatri et al., 2023; Kaur et al., 2024). Two spices are of particular interest: cinnamon, derived from the inner bark of trees in the genus *Cinnamomum* (Lauraceae), and turmeric (*Curcuma longa*), a rhizomatous herbaceous plant in the Zingiberaceae family.

These spices, originally from Sri Lanka and South Asia, respectively, are widely used in diet and phytotherapy. Rich in polyphenols and other secondary metabolites, they contain curcumin and cinnamaldehyde, which are well-documented for their antioxidant, anti-inflammatory, and antimicrobial properties (Kaur et al., 2024; Guo et al., 2024).

The present study aims to investigate the synergistic effect of the cinnamon–turmeric combination using an in vitro approach. Specifically, the study evaluates the combination's antioxidant, anti-hemolytic, and anti-inflammatory activities to highlight its potential relevance to human health. The experimental design uses assays such as protein denaturation inhibition and erythrocyte membrane stabilization to provide a framework for understanding the therapeutic potential of this plant-based synergy.

MATERIAL AND METHOD

This study used a mixture of cinnamon (*Cinnamomum verum*) inner bark and turmeric (*Curcuma longa*) rhizomes as plant materials. Both were obtained from a local herbalist in the Wilaya of Tlemcen in western Algeria. The materials were then dried and ground into a fine powder using an automatic grinder before undergoing extraction procedures (Figure 1).

Turmeric (*Curcuma longa*)

Cinnamon (*Cinnamomum verum*)

Figure 1: Turmeric rhizomes (*Curcuma longa*), turmeric powder and cinnamon bark (*Cinnamomum verum*) after grinding

Two types of extracts were prepared from the cinnamon-turmeric mixture. The methanolic extract was obtained by macerating 50 g of the powdered mixture in a 80:20 methanol-water solution for 24 hours. This process was repeated three times with fresh solvent. The combined filtrates were concentrated under reduced pressure at 40 °C, and the residue was dried and stored at 4 °C.

The aqueous extract was obtained by boiling 50 g of powder in 500 mL of distilled water for 30 minutes. After filtration, the filtrate was dried at 30 °C for 72 hours and stored at room temperature. The extraction yield was calculated as the ratio of the dry extract mass to the initial plant material mass, expressed as a percentage according to the following equation:

$$Re = (Me/Mv) \times 100$$

where Me is the mass of the dry extract obtained (g) and Mv is the initial mass of the plant material (g).

Phytochemical screening revealed the following results: Alkaloids were tested by treating 2 mL of extract with 2 mL of Wagner's reagent. The appearance of a yellow-white precipitate indicated a positive reaction (Maria et al., 2018). Tannins were identified by adding a few drops of 0.1% ferric chloride (FeCl₃) to 2 mL of the extract; a dark green color confirmed their presence (Warnasih et al., 2019). Sterols were detected using the Liebermann-Burchard test. The addition of 5 mL of acetic anhydride and 1 mL of concentrated sulfuric acid to 5 mL of the extract without shaking produced a red-brown ring and violet layer (Khan et al., 2012). Flavonoids were identified by treating 2 mL of the extract with a few drops of 37% HCl and 0.5 g of magnesium filings, which resulted in red or orange coloration (Saxena et al., 2013). Terpenoids were identified by adding 1 mL of chloroform and 1.5 mL of concentrated sulfuric acid to 2.5 mL of the extract. This produced two phases with a brown interface (Yadav & Agarwala, 2012). Cardiac glycosides were tested by dissolving 2 mL of the extract in chloroform and carefully adding 2 mL of concentrated sulfuric acid, yielding a reddish-brown

ring at the interface (Harborne, 1973). Anthocyanins were detected by adding 3 mL of 10% H_2SO_4 and 1 mL of 10% NH_4OH to 1 mL of the extract. This produced an intensified red color in an acidic medium and a blue shift in an alkaline medium (Diallo, 2000). Anthraquinones were tested by mixing 5 mL of the filtrate with an ammoniacal solution. A pink or violet color in the ammoniacal phase indicated a positive result (Odebeyi & Sofowora, 1978). Volatile oils were detected by adding 0.1 mL of 10% sodium hydroxide and a few drops of 10% diluted hydrochloric acid to 2 mL of the extract. This yielded a white precipitate (Mojab et al., 2003).

The quantitative determination of total polyphenols was carried out using the Folin–Ciocalteu reagent, as described by Wong et al. (2006). The reagent consists of phosphotungstic acid ($\text{H}_3\text{PW}_{12}\text{O}_{40}$) and phosphomolybdic acid ($\text{H}_3\text{PMo}_{12}\text{O}_{40}$) and is reduced during the oxidation of phenols. This reaction forms blue oxides of tungsten and molybdenum (Ribéreau, 1968). The resulting coloration, with maximum absorbance at 765 nm, is proportional to the polyphenol content (Ghazi & Sahraoui, 2005). Evaluation followed the protocol of Li et al. (2007). Briefly, 200 μL of each extract were added to 1 mL of Folin–Ciocalteu reagent diluted 10-fold in distilled water. After a 4-minute incubation period, 800 μL of a 75 g/L sodium carbonate solution were added. The mixture was then incubated for 30 minutes in the dark at room temperature, after which the absorbance was measured at 765 nm. Total polyphenol concentration was determined using a gallic acid calibration curve and expressed as milligrams of gallic acid equivalents per gram of dry extract (mg GAE/g DE).

Total flavonoid content was determined using the aluminum chloride (AlCl_3) colorimetric method described by Lamaison and Carnet (1990). Briefly, 1 mL of the extract solution was mixed with 1 mL of a 2% AlCl_3 solution. The mixture was shaken vigorously and incubated for 10 minutes. Absorbance was then measured at 367 nm. Flavonoid content was calculated using a calibration curve prepared with rutin and expressed as micrograms of rutin equivalents per milligram of dry extract.

Condensed tannins were quantified using the vanillin-HCl method (Julkunen-Tiitto, 1985). This method is based on the formation of red complexes between vanillin and the terminal flavonoid groups of condensed tannins, which may convert further into anthocyanidols. In practice, 50 μL of the extract were mixed with 1.5 mL of a 4% vanillin/methanol solution, followed by the addition of 750 μL of HCl. The mixture was kept at room temperature for 20 minutes, after which the absorbance was measured at 550 nm. A calibration curve was established using catechin (100–700 $\mu\text{g/mL}$).

The antioxidant capacity was evaluated using the ferric reducing antioxidant power (FRAP) assay, as described by Yildirim et al. (2001). This method is based on the reduction of the ferricyanide complex (Fe^{3+}) to ferrous iron (Fe^{2+}) in the presence of antioxidants, which yields a green color proportional to the reducing power (Gülçin et al., 2003). For the assay, 2.5 mL of phosphate buffer (0.2 M, pH 6.6) and 2.5 mL of 1% potassium ferricyanide were added to 1 mL of the extract. After incubating for 20 minutes at 50 °C, 2.5 mL of trichloroacetic acid (10%) was added, and the mixture was centrifuged at 3,000 rpm for 10 minutes. Then, 2.5 mL of the supernatant were mixed with 2.5 mL of distilled water and 0.5 mL of FeCl_3 (0.1%). Absorbance was measured at 700 nm. The results were expressed as μg of ascorbic acid equivalents per mg of dry extract (μg AAE/mg DE).

The scavenging activity of the stable radical 2,2-diphenyl-1-picrylhydrazyl (DPPH) was assessed using the technique described by Sánchez-Moreno et al. (1998), with modifications. In this assay, 1,950 μL of the DPPH-methanol mixture (0.025 g/L) were mixed with 50 μL of various extracts at different concentrations. After incubating for 30 minutes at ambient temperature, absorbance was measured at a wavelength of 515 nm against a blank. Then, the DPPH free radical scavenging activity, expressed as a percentage, was calculated using the following formula:

$$I(\%) = (A_c - A_s / A_c) \times 100$$

where A_c and A_s represent the absorbance values of the control and the sample, respectively.

Anti-hemolytic activity was evaluated using the human erythrocyte membrane stabilization method. First, a 10% erythrocyte suspension was incubated with the extracts in the presence of a hyposaline solution. Then, the mixture was centrifuged. Then, the absorbance of the supernatant was measured at 560 nm. The percentage of hemolysis inhibition was calculated by comparing it to the inhibition of hemolysis by gallic acid, which was used as a positive control.

$$\text{Inhibition of hemolysis (\%)} = [(A_c - A_t) / A_c] \times 100$$

where A_c is the absorbance of the control sample and A_t is the absorbance of the test sample.

Anti-inflammatory activity was assessed by measuring the inhibition of the thermal denaturation of bovine serum albumin (BSA). A 0.2% BSA solution was incubated with various extract concentrations (100–500 $\mu\text{g/mL}$) before being heated to 72 °C. Absorbance was measured at 660 nm, and the percentage inhibition was calculated using diclofenac sodium as the reference standard according to the following equation:

$$\text{Inhibition (\%)} = 100 - [(A_t - A_c) / A_t] \times 100$$

Where A_t is the absorbance of the test solution (extract) and A_c is the absorbance of the control.

Statistical Analysis

All results are expressed as mean $\pm$ standard error. Statistical analysis was performed using Excel 2021.

RESULTS AND DISCUSSION

Extraction Yield

The extraction of the *Cinnamomum verum*–*Curcuma longa* mixture revealed a higher yield with water (16.36%) compared to methanol (12.96%) (Table 1). This difference can be explained by the high polarity of water, which favors the extraction of water-soluble metabolites such as polysaccharides, glycosides, and certain polyphenols. Methanol, although polar, exhibits lower affinity for some hydrophilic fractions, which accounts for its slightly reduced yield. These results corroborate the observations of Hegde et al. (2012), who highlighted the effectiveness of water as an extraction solvent for spices rich in phenolic compounds.

Table1: Extraction Yield (%) of Methanolic and Aqueous Extracts of the Cinnamon-Turmeric Mixture

Extraction Solvent	Methanolic extract	Aqueous extract
Yield (%)	13.25	16.36

Qualitative Phytochemical Screening

Phytochemical screening, performed according to standardized methods (Nguyen et al., 2020), revealed the presence of major secondary metabolites — phenols, flavonoids, anthraquinones, and glycosides — while no sterols or Anthocyanins were detected (Table 2). This molecular diversity suggests that the cinnamon–turmeric combination concentrates bioactive compounds that account for its reported biological activities, particularly its antioxidants and anti-inflammatory effects (Sana et al 2019; Muazu et al. 2021; Fuloria et al., 2022; Pagliari et al., 2023).

Quantitative Phytochemical Analysis

Quantitative assessment (Figure 2) revealed a particularly high content of polyphenols in the aqueous extract, followed by flavonoids, terpenoids, and tannins. These results confirm the hypothesis that water is the most effective solvent for polyphenol extraction (Piba et al., 2021). The richness in polyphenols, well known for their strong antioxidant power, confers notable pharmacological potential to these extracts (Sana et al 2019; Nakae et al., 2023).

Biological Activities (Antioxidant, Anti-hemolytic, and Anti-inflammatory)

The radical scavenging activity, evaluated by DPPH and FRAP assays (Figure 3), showed that the methanolic extract exhibited the highest DPPH scavenging activity (23.28 ± 7.40) and 14.47 ± 4.43 mg Trolox equivalents/g DW), probably due to its higher alkaloid content (Dieng et al., 2017). However, the FRAP assay confirmed that both extracts possess significant reducing power, attributable to their richness in polyphenols (Sana et al 2019).

Table 2: Results of Phytochemical Tests of Different Extracts of the Cinnamon-Turmeric Mixture

Volatile Oils Test	+	+

+: Low presence; ++: Moderate presence; +++: High presence; —: Absence

Figure 2: Total Phenolic Content of the Extracts

In parallel (figure 4) , the anti-hemolytic activity assessed on human erythrocytes revealed a stable and dose-dependent inhibition for the decoction (74.22–85.91% at 500 $\mu\text{g/ml}$), approaching the efficacy of diclofenac (89.35% at 500 $\mu\text{g/ml}$). The methanolic extract showed a peak activity at 150 $\mu\text{g/ml}$ (86.17%), followed by a marked decrease at higher concentrations. In addition, the aqueous extract inhibited thermal hemolysis more effectively than diclofenac at different concentrations, the latter being a conventional non-steroidal anti-inflammatory drug (NSAID) that is well known and widely used worldwide in the treatment of inflammatory diseases (Procházková et al., 2011).

Anti-inflammatory activity, measured by the inhibition of protein denaturation, demonstrated a moderate, dose-dependent response: 31.85–57.42% for the decoction, 28.73–52.38% for the maceration, compared to 71.63% for diclofenac at 500 $\mu\text{g/ml}$. These findings suggest a protective effect linked to the synergistic action of flavonoids and terpenoids, capable of modulating pro-inflammatory signaling pathways (NF- κB , COX-2). The thermal process of decoction, by inactivating polyphenol oxidase (PPO), also helps to preserve thermostable compounds (Zawawi et al., 2022; Antony and Farid, 2022).

Overall, the cinnamon–turmeric mixture emerges as a rich source of bioactive secondary metabolites. The differences observed between aqueous and methanolic extracts reflect solvent selectivity and the importance of extraction conditions. The aqueous extract combines ethnopharmacological relevance, efficient extraction, and biological stability, whereas the methanolic extract, richer in alkaloids, exhibits strong antioxidant activity but less stability at higher concentrations. These findings support the rational valorization of the mixture in phytotherapy and highlight the need for further studies, particularly *in vivo*, to confirm its efficacy and clinical safety.

Figure 3: Antiradical Activity of the Extracts (DPPH and FRAP Assays)

Figure 4: In vitro evaluation of the anti-hemolytic (A) and anti-inflammatory (B) activity

CONCLUSIONS

Based on the study, the cinnamon–turmeric synergy, especially in decoction form, stands out for its dual protective bioactivity, highlighting its potential in the formulation of phytopharmaceuticals targeting oxidative and inflammatory conditions.

ABSTRACT

Retinoscopy is a fundamental examination method that has been used for many years in the objective evaluation of refractive errors such as myopia, hyperopia, and astigmatism in the fields of ophthalmology and optometry. In recent years, with the digitalization of this technique, innovative tools such as smartphone-assisted systems and the GimbalScope have gained increasing attention. The literature emphasizes the advantages of the GimbalScope in educational settings, including real-time visualization, low cost, and high portability. Furthermore, AI-based systems have been shown to enhance effectiveness in both education and clinical diagnosis by automating the classification of retinoscopic reflexes. In this study, an AI model is planned to be developed to classify retinoscopic reflexes using publicly available datasets. This model aims to bridge theory and practice by proposing a sample system that can be applied particularly in healthcare technologies and optometry education. The proposed approach is expected to enable faster detection of refractive errors and increase access to eye examinations for a broader population.

Keywords: Retinoscopy, GimbalScope, Refractive Error, Artificial Intelligence, Biomedical Diagnosis

INTRODUCTION

The idea of retinoscopy was first proposed by the ophthalmologist Cuignet in the 1800s (Enaholo et al., 2023; Pai-Dhungat et al., 2014; Norn, 2016; Hallak, 1976). Retinoscopy is a technique currently used to detect refractive errors, including myopia, hyperopia, and astigmatism (Musa et al., 2024). Retinoscopy helps determine the eyeglass prescription that should be used to correct a person's refractive errors. In recent years, retinoscopy has continued to develop, influenced by artificial intelligence (Mendez, A., 2016). Chan and colleagues combined a retinoscope and a smartphone camera to create a digital retinoscope (Chan et al., 2014). When we look at the studies on the subject in recent years, we see that interest in smartphone-supported systems has increased, and exciting innovations such as the GimbalScope have emerged.

This new technology provides real-time visualization during training and also attracts attention due to its affordability and portability (Chandrakanth et al., 2022). Furthermore, AI-supported systems have demonstrated the ability to improve training and clinical outcomes through automation in the classification of the retinoscopic reflex (Krishnan et al., 2025). However, studies evaluating the performance of AI models based on publicly available datasets

for the classification of retinoscopic reflexes remain limited. This makes it difficult to standardize comparisons and evaluations.

In this study, Simple CNN and ResNet-18 were used as different deep learning models for the RetinaMNIST dataset, and their performances were examined. Thus, we evaluated the impact of model architecture, data preprocessing (grayscale and RGB), training time, and data augmentation on classification accuracy. The findings from this study provide new ideas for integrating AI-assisted retinoscopy into ophthalmology education and clinical practice.

MATERIAL AND METHOD

This study was conducted on the RetinaMNIST dataset, which consists of 2D retinal fundus images divided into five classes: myopia, hyperopia, astigmatism, normal, and other (Yang et al., 2023). The grayscale image database was initially resized into 224×224 pixels from the original size of 28×28 pixels, and grayscale and RGB transformations were the preprocesses performed over the database. To improve generalization, data augmentation techniques were applied in selected experiments. Two architectures were implemented: a Simple CNN and a ResNet-18 model for five-class classification, where layer freezing and dropout were additionally explored. Training was carried out for 10–30 epochs, and early stopping along with learning rate scheduling was employed to prevent overfitting. Model performance was evaluated in terms of training and test accuracy, which provided insights into the effectiveness of the models under different configurations.

RetinaMNIST was selected because it provides a benchmark setting for evaluating automated refractive error detection while reflecting the visual complexity of retinoscopy. Nevertheless, its limited size and clinical diversity impose constraints on generalization performance, motivating the use of preprocessing strategies, transfer learning, and data augmentation in subsequent experiments.

RESULTS AND DISCUSSION

The experiments on the RetinaMNIST dataset revealed that achieving high classification accuracy remains a challenge due to dataset complexity and class imbalance. The Simple CNN model reached a maximum test accuracy of **53.50%**, both with grayscale images trained for 30 epochs and when grayscale images were converted into RGB format. Despite its shallow architecture, the CNN provided competitive results when training duration or preprocessing was optimized. The ResNet-18 model slightly outperformed the CNN, achieving the **highest test accuracy of 53.75%** with RGB images at 10 epochs. However, increasing the number of epochs or applying pretrained weights did not consistently enhance performance, and in some cases even reduced accuracy (e.g., **46.75%** with pretrained weights at 20 epochs). Data augmentation and fine-tuning techniques such as layer freezing and dropout yielded moderate improvements but did not surpass the best-performing configurations. Overall, the accuracy values across both models ranged from **46% to 54%**, consistent with literature reporting relatively low performance on RetinaMNIST (Halder et al., 2024; Neghawi and Liu, 2024). These results highlight the difficulty of generalization in small, imbalanced biomedical datasets, where overfitting is a persistent issue. Future improvements may involve applying transfer learning from large-scale pretrained networks, exploring transformer-based architectures (e.g., ViT, Swin Transformer), and utilizing larger, more diverse retinal image datasets. From a practical standpoint, integrating AI-based classification with portable devices such as the Gimbalscope could provide scalable, cost-effective support in both clinical diagnostics and medical education.

Table 1. Comparison of model performance for the RetinaMNIST dataset

Model	Data Preprocessing	Epochs	Train Accuracy (%)	Test Accuracy (%)
Simple CNN	Grayscale	10	50.37	50.75
Simple CNN	Grayscale	30	51.11	53.50
Simple CNN	RGB	10	54.26	53.50
ResNet-18	RGB	10	68.24	53.75
ResNet-18	RGB	20	59.26	46.75
ResNet-18	Grayscale	20	54.54	48.00
ResNet-18	RGB + Augmentation	10	55.65	52.00
ResNet-18	RGB, Layer Freeze + Dropout	20	56.94	52.25

Figure 1. Example classification results on the RetinaMNIST dataset using ResNet-18.

Figure 1 shows sample predictions of the ResNet-18 model on the RetinaMNIST dataset, showing ground truth (GT) and predicted labels (Pred). Classes: Myopia, Hyperopia, Astigmatism, Normal, Other. In most cases, the ground truth and predicted classes are consistent, indicating that the model is capable of distinguishing major refractive errors. However, some misclassifications are observed between Myopia and Hyperopia, which are clinically similar categories. The results highlight both the potential and the limitations of deep learning based approaches in automated refractive error detection.

CONCLUSIONS

This study presented a comparative analysis of different deep learning models with experimental evaluation using the RetinaMNIST dataset. The CNN and ResNet-18 models achieved maximum test accuracies of 53.50% and 53.75%, respectively, which are consistent with results reported in the literature. While these accuracy levels highlight the challenges posed by the limited size and complexity of RetinaMNIST, the proposed framework underscores the potential of AI-assisted retinoscopy in both clinical and educational applications. Future work will focus on expanding dataset diversity, implementing advanced deep learning architectures such as Vision Transformers, and evaluating integration with real-world retinoscopy systems.

ABSTRACT

The use of *Nigella sativa* L., commonly known as black cumin, in traditional and medicinal practices is well-documented, due to the wide range of its biological activities. In light of its significance, this study investigates the efficacy of various seed priming treatments, specifically Gibberellic Acid (GA₃) and different priming durations, under laboratory conditions to enhance the germination stages of *Nigella sativa* L. The objective of these priming treatments is to improve germination rates, the germination index, and average germination time, with the potential to increase agricultural productivity.

The findings of this study demonstrate that priming durations and gibberellic acid doses have a significant impact on germination parameters under controlled conditions. These results provide valuable insights into the potential of these treatments to optimise crop growth. It can be concluded that appropriate seed priming can effectively enhance the early growth stages of *Nigella sativa* L., contributing to better crop establishment and yield.

Keywords: *Nigella sativa* L., Seed priming, Gibberellic Acid (GA₃), Germination rates, Germination index

INTRODUCTION

Medicinal plants, especially those with a broad spectrum of biological activities, have attracted considerable attention in both the scientific and medical fields. *Nigella sativa* L., commonly known as black cumin or black seed and belonging to the Ranunculaceae family, is notable for its widespread use in culinary and medicinal contexts (Mohamed et al., 2014; Kiralan et al., 2016). Its medicinal use has attracted worldwide interest, largely due to its efficacy in the treatment of numerous conditions. Historical accounts, including those attributed to the Prophet Muhammad, have enhanced the reputation of black seed as a remedy for various ailments, except death itself (Islam et al., 2019).

Traditionally, *Nigella sativa* seeds have been used to treat conditions such as fatigue, persistent headaches and melancholy. Roasted seeds mixed with honey or butter have been suggested to relieve colic and coughs, while the seeds are known for their lactogenic and antiseptic properties, particularly in the treatment of eye infections. The emergence of COVID-19 has

further sparked interest in potential antiviral treatments, with studies investigating *Nigella sativa* extracts for their ability to inhibit coronavirus replication and affect TRP gene expression during infection (Ulasli et al., 2014). The results suggest that *Nigella sativa* has a significant effect on viral load and gene expression associated with CoV infection, enhancing its therapeutic potential (Yimam et al., 2015).

The genus *Nigella* includes around 20 species, 14 of which are found in Türkiye (Nemtinov et al., 2022). It is cultivated globally, from Southern Europe to the Middle East and South Asia, and is particularly widespread in regions like Thrace, Northern Anatolia, and the Mediterranean in Türkiye, especially in provinces like Burdur, Afyon, Isparta, and Gaziantep (Inan et al., 2022).

Seed priming, a cost-effective method to promote early crop growth and uniform emergence, is a common agricultural practice. This involves treating seeds with osmotic solutions or plant growth promoters such as salicylic acid and gibberellic acid, or inorganic salts like KNO₃ and CaCl₂ (Farooq et al., 2008; Rehman et al., 2011). Priming typically accelerates germination, improves stand establishment, and enhances crop yield and quality. For example, KNO₃ priming not only speeds up germination and strengthens seedlings but also boosts yield and protein content when combined with other priming methods (Rehman, 2014).

A substantial body of research has demonstrated that a variety of priming techniques can positively influence seed germination and seedling growth (Paparella et al., 2015; Sharma et al., 2014; Khalaki et al., 2020). The primary objective of this study is to determine the optimal dose and duration of gibberellic acid (GA₃) application for seed priming in *Nigella sativa*, with the aim of enhancing seed germination. While the study also aims to explore whether these optimal conditions observed in controlled laboratory settings can be effectively applied in field conditions, the central focus remains on identifying the most effective GA₃ treatment parameters to improve seed germination.

MATERIAL AND METHOD

This study examines the impact of , Gibberellic Acid (GA₃), priming treatments on *Nigella sativa* L. seeds under controlled laboratory conditions. The seeds were subjected to germination tests, placed on four layers of moistened filter paper, and incubated in darkness at a constant temperature of 22°C. Germination was assessed by the emergence of a 1 mm radicle and monitored over a 10-day period. No signs of microbial contamination were observed during the experiment (Kamal et al., 2010).

For priming, there are four dose; Control dose, 100 ppm GA, 200 ppm GA and 300 ppm GA; three priming duration; 12 hour Priming, 24 hour Priming and 36 hour Priming applications. The experimental design was arranged in a completely randomized design with 4 replications of 25 seeds in the germination stage. The seeds were placed in 10 × 10 cm plastic boxes lined with blotting paper.

Germination Rate (%): It is calculated as Scott et al., 1984.

$$GR = \frac{\text{Number of germinated seeds}}{\text{Total number of seeds}} * 100$$

Germination Index: The germination index is calculated by dividing the number of germinated seeds by the number of days to the first count, and adding that to the number of germinated seeds divided by the number of days to the final count (Benech Arnold et al., 1991).

Mean germination time (Day): It is calculated as Ellis & Roberts, 1981.

$$MGT = \frac{\sum(Dn)}{\sum n}$$

n : number of seeds germinated on day D,

D: number of days counted from the beginning of the germination the lightest seeds,

The obtained data were analyzed separately and differences were determined using the analysis of variance (one-way ANOVA). Variance analyses were performed using JMP Pro v.16 software. Statistically significant factors were grouped using the LSD (Least Significant Difference) test. Factors that were not significant in the LSD test were compared based on mean tables.

RESULTS AND DISCUSSION

The ANOVA analysis results highlight the significant effects of GA₃ (gibberellic acid) dosage and application time on the germination performance of *Nigella sativa* seeds. The results show that both factors have statistically significant impacts on parameters such as germination rate, germination index, and mean germination time. The GA₃ dosage has a highly significant effect on the germination rate at the 1% level ($p < 0.01$). Different GA₃ concentrations lead to noticeable differences in the seeds' germination success. Additionally, application time also significantly affects germination rate at the 1% level ($p < 0.01$), indicating that the duration of exposure to GA₃ plays an important role. However, the interaction between dosage and time was not statistically significant ($p > 0.05$), suggesting that the combined application of these two factors does not create a synergistic effect. GA₃ dosage significantly affects the germination index at the 5% level ($p < 0.05$), meaning that varying doses impact the rate of germination, though not as dramatically as for germination rate. On the other hand, application time did not significantly influence the germination index ($p > 0.05$), indicating that time does not largely affect germination speed. GA₃ dosage significantly affects the mean germination time at the 1% level ($p < 0.01$), showing that optimal dosages can shorten the time it takes for seeds to germinate. Similarly, application time also has a significant effect on the mean germination time at the 1% level ($p < 0.01$), indicating that longer exposure to GA₃ can alter the germination process. However, the interaction between dosage and time did not significantly affect this parameter ($p > 0.05$) (Table 1).

These findings suggest that both GA₃ dosage and application time should be optimized independently to improve the germination performance of *Nigella sativa* seeds. The lack of a significant interaction between the two factors means that their combined application does not offer additional advantages, so it is important to focus on each factor separately for better results.

Table 1. Significance levels in variance analysis for the GA₃ priming dose applications and priming durations in *Nigella sativa* L. Plant.

Source of Variation	Df	Mean of Square		
		Germination Rate	Germination Index	Mean germination time (Day)
Rep.	2	21.33	0.127	0.048
Dose	3	564.74**	1.369*	0.173**
Time	2	112**	0.098	0.497**
Dose*Time	6	40.29	0.151	0.131
Error	22	21.33	0.9	0.053
Total	35			

The results presented in Table 2 show the effects of different GA₃ doses and priming times on the germination parameters of mean value *Nigella sativa* seeds.

The 300 ppm GA₃ dose consistently yielded the highest germination rates across all priming times, with an average of 92.00%, significantly outperforming the control (72.88%) and lower GA₃ doses. The dose of 300 ppm GA₃ resulted in significantly higher germination compared to the other treatments ($p < 0.01$). When considering priming duration, 36-hour priming resulted in the highest average germination rate of 85.32%, followed by 12-hour (81.33%) and 24-hour (79.33%). The effect of the priming time was significant, indicating longer priming times positively influence germination rates. A similar trend is observed with the germination index. The highest index (4.05) was found in seeds primed with 300 ppm GA₃, indicating faster and more successful germination compared to the control (3.14) and other GA₃ concentrations. The effect of the dose on the germination index was statistically significant ($p < 0.05$). Among the priming durations, the 12-hour priming time slightly outperformed others with an average germination index of 3.57, though the differences between priming times were not as pronounced. Regarding the average germination day, seeds primed with 300 ppm GA₃ also exhibited the fastest germination, averaging 6.08 days. This was significantly faster compared to seeds primed with 200 ppm GA₃ (6.40 days) and the control (6.18 days). The effect of GA₃ dose on germination time was significant at $p < 0.01$. The longest germination time was recorded at the 36-hour priming duration (6.45 days), suggesting that longer priming may slow down the germination process, while shorter priming durations (12 and 24 hours) resulted in quicker germination.

Table 2. Effect of GA₃ priming dose applications and priming durations in *Nigella sativa* L. plant germination parameters.

GA Dose and Priming Time	Germination Rate				Germination Index				Average Germination Day			
	12 hour Priming	24 hour Priming	36 hour Priming	Avg.	12 hour Priming	24 hour Priming	36 hour Priming	Avg.	12 hour Priming	24 hour Priming	36 hour Priming	Avg.
Control	73.33	70.66	74.66	72.88 C	3.19	3.12	3.11	3.14 C	6.07	6.09	6.39	6.18 AB
100 ppm GA	81.33	72	86.66	80.00 B	3.61	2.94	3.5	3.35 BC	6.01	6.48	6.41	6.30 AB

CONCLUSION

The results of the analysis of GA₃ priming doses and durations on *Nigella sativa* seeds provide several key insights for optimising germination performance. The highest germination rates, germination index values and shortest average germination times were achieved with a GA₃ concentration of 300 ppm. This dose significantly improved germination performance compared to lower doses and the control, demonstrating its effectiveness in promoting faster and more successful seed germination. Of the different priming durations, 36 hours priming resulted in the highest average germination rate, but also resulted in a slightly longer average germination time. This suggests that while longer priming durations may improve the overall germination rate, they may also increase the time taken for seeds to germinate. Conversely, shorter priming durations (12 and 24 hours) tended to speed up the germination process, but with less pronounced improvements in germination index compared to the 36 hour priming. The results suggest that the GA₃ dose of 300 ppm combined with a 12- or 24-hour priming period may be the most balanced approach, providing high germination rates and relatively short germination times. The effect of the interaction between dose and priming time was not as significant as the individual effects of each factor. In conclusion, a GA₃ dose of 300 ppm is highly recommended to enhance the germination of *Nigella sativa* seeds, with 12 h or 24 h priming preferred for faster germination. Longer soaking times may be beneficial for overall germination rates but may slightly delay the germination process. Balancing these factors according to the specific needs of the seed and the desired results can lead to optimum germination performance.

SPATIOTEMPORAL PATTERNS OF TRACE ELEMENTS (LI, MN, NI, BA) IN RIVERS FEEDING THE İSTANBUL STRAIT, TÜRKİYE

Cem Tokatlı

Trakya University, İpsala Vocational School, Edirne / Türkiye

cemtokatli@trakya.edu.tr

ABSTRACT

Sediments in freshwater ecosystems are crucial reservoirs of both essential and toxic elements. While some elements are vital for life, prolonged or high-level exposure, much like with non-essential toxic elements, can be detrimental. The Istanbul Strait, a globally significant marine habitat in northwestern Türkiye, receives substantial input from numerous rivers and lakes. This study investigated the spatiotemporal variations and accumulation of lithium (Li), manganese (Mn), nickel (Ni), and barium (Ba) in the sediments of rivers flowing into the İstanbul Strait. In this research, sediment samples were collected from three key fluvial habitats (Göksu, Kağıthane and Alibeyköy streams) during the dry and wet seasons of 2022–2023. The findings of the study reveal that the average annual concentrations of these elements in the river sediments followed the order: Mn (542.585 ppm) > Li (33.905 ppm) > Ni (21.598 ppm) > Ba (0.425 ppm). Furthermore, significant seasonal differences were observed in trace element accumulations. Notably, average concentrations of Li, Mn, Ni, and Ba in the sediments increased approximately 11, 3, 1.5, and 2 times, respectively, during the wet season.

Keywords: İstanbul Strait, Riverine habitats, Sediment quality, Trace elements

INTRODUCTION

Manganese, an essential element, is crucial for the healthy growth and development of all living organisms. However, much like toxic elements such as lithium, nickel, and barium, an excess of even essential elements can negatively impact the environment. Therefore, maintaining trace elements at concentrations below harmful limits and ensuring a balanced presence of essential elements in aquatic habitats is paramount for environmental protection (Milne, 2000; Belitz et al., 2009; Köse et al., 2013; Çiçek et al., 2013; 2017; Tokatlı and Helvacıoğlu, 2020).

Freshwater sediments play a crucial and dual role in aquatic ecosystems. Not only do they act as transporters and reservoirs for numerous pollutants, but they also offer a rich archive of valuable environmental information (Tokatlı et al., 2014; Yüksel et al., 2024; Varol and Tokatlı, 2024). This makes their study indispensable for understanding the health and history of water bodies. Consequently, the analysis of elemental content in surface sediments is a vital practice for environmental monitoring and assessment (Varol et al., 2022; Ustaoglu et al., 2022; Tokatlı and İslan, 2022). By examining these elemental signatures, researchers can gain insights into past and present anthropogenic impacts, natural geological processes, and the overall ecological status of freshwater habitats.

The Istanbul Strait stands as a critically important international marine habitat in northwestern Türkiye. Its extensive watershed, teeming with numerous rivers and lakes, unfortunately also subjects this vital aquatic environment to significant pollution stress (Tokatlı et al., 2023; 2024; Varol and Tokatlı, 2024). In this study, the accumulation and spatiotemporal distribution of lithium (Li), manganese (Mn), nickel (Ni), and barium (Ba) were investigated in

the sediments of the rivers that feed directly into the Istanbul Strait and the implications of these findings for ecosystem health in the region were evaluated.

MATERIALS AND METHODS

For this study, three fluvial ecosystems feeding the Istanbul Strait were selected (Figure 1). Surface sediment samples were then collected from the downstream locations of these rivers during both the wet season (end of winter) and dry season (end of summer) of 2022–2023. An Ekman Grab (Hydrobios) was used for sample collection, adhering to the standard protocol (EPA, 2001a).

To determine the concentrations of lithium (Li), manganese (Mn), nickel (Ni), and barium (Ba) in the sediment samples, each sample was first dried at 105 °C for 3 hours. For digestion, 0.25 g of each dried sample was placed into a CEM Mars Xpress microwave device. A mixture of acids, specifically perchloric acid (HClO₄) and nitric acid (HNO₃) in a 1:3 ratio, was added to the Pyrex reaction vessels. The samples then underwent mineralization by heating at 200 °C for 30 minutes. Following mineralization, the samples were filtered using a 0.45 µm cellulose nitrate filter. After filtration, ultrapure water was added to bring the final volume of each sample to 100 mL. The concentrations of these trace elements in the sediments were then precisely measured using an Agilent 7700 ICP-MS device. All measurements were performed in triplicate at the accredited (TS EN / ISO IEC 17025) central laboratory of Thrace University in Edirne, Türkiye (EPA, 1998; 2001b).

Figure 1. Study area and selected sampling locations

RESULTS AND DISCUSSION

Figure 2 presents the determined concentrations of lithium (Li), manganese (Mn), nickel (Ni), and barium (Ba) in the sediments collected from the designated sampling locations on the Göksu, Kağıthane, and Alibeyköy streams. These values illustrate the spatial distribution of the selected elements, offering valuable insights into the elemental composition of sediments within these fluvial water bodies during the sampling periods.

In the investigated streams, clear seasonal and spatial variations were observed in trace element concentrations. Lithium increased markedly during the wet season, reaching 112.159 ppm in Göksu Stream, compared to much lower values in the dry period (3.044–9.597 ppm). Manganese also exhibited a strong rise in the wet season, with the highest concentration measured in Göksu Stream (1248.808 ppm), whereas dry season levels remained between 234.523 and 359.089 ppm. Nickel showed site-dependent fluctuations, being higher in Kağıthane Stream during the dry season (25.156 ppm) and in Alibeyköy Stream during the wet season (35.766 ppm). Barium, on the other hand, remained at relatively low concentrations (0.183–0.411 ppm in the dry season), though it increased in the wet season, particularly in Alibeyköy Stream (0.764 ppm). These results indicate that wet season conditions, influenced by surface runoff, erosion, and anthropogenic inputs, considerably enhance the mobilization of certain elements, especially Li and Mn.

The pronounced seasonal increases in Li and Mn, particularly during the wet season, suggest that hydrological dynamics play a major role in the mobilization of these elements. Increased precipitation enhances surface runoff and leaching, resulting in the transport of metals from surrounding soils and anthropogenic sources into the streams. Elevated Ni and Ba concentrations in Alibeyköy and Kağıthane Streams further indicate the influence of urban and industrial discharges, which are well-documented contributors to trace metal pollution in densely populated catchments. Similar spatial and temporal patterns in trace metal accumulation have also been reported in previous studies conducted in Turkish aquatic ecosystems (Arslan et al., 2012; Tokatlı et al., 2020; Din et al., 2023; Ustaoglu et al., 2025; Ali et al., 2025). Overall, the results highlight the combined effects of natural processes and anthropogenic pressures on metal dynamics in stream ecosystems.

CONCLUSIONS

This study demonstrated notable spatial and temporal variations in trace element concentrations in the sediments of Göksu, Kağıthane, and Alibeyköy Streams. Lithium and manganese showed remarkable increases during the wet season, suggesting that hydrological processes strongly influence their accumulation in sediments. Nickel and barium exhibited site-specific patterns, reflecting the impact of local anthropogenic pressures, particularly in urbanized catchments. Since these streams discharge directly into the Istanbul Strait, the observed sediment contamination patterns are of particular concern, as they may contribute to the transfer of trace metals into this ecologically and economically critical marine ecosystem. Therefore, continuous monitoring of these inflowing streams is essential to evaluate and mitigate their potential impacts on the Istanbul Strait.

ABSTRACT

This study was conducted during the 2022-2023 period in the experimental plot located at the Çukurova University Pozantı Agricultural Research and Application Center, situated at an altitude of 1200 m. The study focused on the 0900 Ziraat cherry variety grafted onto MaxMa 60 rootstock, planted at a 5x5m spacing, and pruned in a Central Leader system. The trees were five years old. In the study, %0.5 CaCl₂, 300 ppm Green Stim, 100 ppm Chitosan, 400 ppm Thyme oil, combinations of these treatments, and water as a control were used. The study was conducted in a randomized complete block design with 3 replications, each containing 10 plants. As a result of this study, while the control application showed a 36% cracking rate, the lowest fruit cracking rate of 2% was obtained with the Thyme Oil (400 ppm) application. Particularly, the Thyme oil application had positive effects on fruit size. The fruit weight, which was 7.39 g in the control, was determined to be 8.42 g with the Thyme oil application, indicating a positive effect on fruit weight. The best result in fruit firmness was also achieved with the Thyme oil application. While the control had a fruit firmness of 4.5 kg, the Thyme oil application resulted in a fruit firmness of 5.42 kg.

Keywords: Cherry, quality, fruit cracking, essential oil

INTRODUCTION

Cherry (*Prunus avium*) is a type of stone fruit from the Rosaceae family, native to Asia (Özbek, 1978; Webster et al., 1996). Fruits, which constitute an important group among the species belonging to horticultural plants, are of great importance with their production values, growing areas, nutrition and share in exports. Fruits and vegetables are a source of vitamins, minerals, dietary fiber and antioxidants in terms of nutrition. The ratio of water-soluble dry matter, skin color, hardness of the fruit flesh, fruit diameter and weight are the most important criteria affecting consumer preferences in cherry, which is a low-calorie, good source of calcium, potassium and vitamins (vitamins A, B1, B2, C and malic acid) (Wani et al., 2014).

Cherries are produced in a wide area around the world. However, they are mostly produced in Turkey, the USA, Iran and Italy in commercial terms. Turkey, which ranks first in cherry production with the changes in climate conditions and years, is also one of the countries that have a say in cherry exports. Turkey's geographical structure and climate conditions allow for high-quality cherry cultivation suitable for export. The harvest time of cherries grown in Turkey can be earlier than in many European countries, and it extends until August as they rise above sea level (Küden, 2004). Cherries are grown almost everywhere in our country. Cherry production in our country is mainly carried out in the Kemalpaşa district of İzmir, Manisa, Konya-Akşehir, Afyonkarahisar-Sultandağı, Isparta-Uluborlu, Denizli-Honaz and recently in the Konya Hadım

and Taşkent regions. It is also produced in Çanakkale, Kütahya, Mersin, Antalya, Kahramanmaraş, Adana (Saimbeyli), Niğde (Ulukışla), Bursa, Amasya and Sakarya.

The area of cherry orchards in 2023 is 798,622 decares (Figure 1), export value and volume (Figure 2), the production amount is 736,792 tons (TÜİK, 2024).

Figure 1. Turkey's Cherry production area by years

Figure 2. Turkey's Cherry export values and volume by years

One of the most important problems arising from climatic events in cherry cultivation is fruit cracking due to excessive rainfall occurring during harvest time and close to harvest, which causes great economic losses (İmrak et al., 2018; İmrak and Küden 2023). Cracking in cherries occurs in the cuticle of the fruit and generally occurs at 3 points (stalk pit, lateral face, and fruit tip) (Peschel and Knoche, 2005). The most common cause of cracking is accepted as rainwater entering the fruit

shell (Davenport, 1972). Although research on the causes of cracking began in the 1930s, this issue is still debated among scientists (Sekse, 1995). It has been accepted that many factors such as soil moisture, tree-water relations (Sekse, 1995), variety (Christensen, 1972a), fruit maturity stage (Christensen, 1973), soluble substance concentration (Christensen, 1972b), temperature (Christensen, 1972c), stomatal width and frequency (Christensen, 1972b), respiration rate (Pommier, 1989) play an important role in the cracking event.

In the study examining the susceptibility of Fermina, Regina, Lapins and 'Brooks varieties to cracking, it was stated that Regina and Fermina varieties were more resistant than Lapins and Brooks varieties (Moing et al., 2004). It is known that Regina variety is one of the most resistant varieties to fruit cracking (İmrak et al., 2018).

The main purpose taken into consideration in the selection of chemicals applied to reduce cracking is to reduce the amount of rainwater entering the fruit surface as much as possible during and after heavy rain. In many areas, calcium-containing solutions and the use of calcium together with substances such as copper, sulfate, nitrate are used against fruit cracking, as well as antitranspirants and various surface waxes (Sekse, 1995).

In cherry cultivation, calcium-containing solutions, which are used intensively to reduce cracking, are used effectively in many areas 2-3 weeks before harvest (Brown et al., 1995). In calcium applications, calcium blocks cell wall pectins, making the cell wall resistant to pressure and cracking (Alani, 1980).

In recent years, many applications have been made to prevent cracking, and one of them is the application of 0.5 mM methyl jasmonate applied in the pre-harvest period, which is stated to have a positive effect in preventing fruit cracking by increasing tolerance to abiotic stress (Ruiz-Aracil et al., 2023)

In the research, it was aimed to prevent cracking in the fruits of 0900 Ziraat cherry variety for export, caused by excessive rainfall during harvest time, by applying Calcium Chloride (CaCl_2), Green Stim, Chitosan and Thyme oil, thus increasing the quantity and quality of fruit for export.

MATERIAL AND METHOD

This study was carried out on 5-year-old 0900 Ziraat cherry variety grafted onto MaxMa 60 rootstock, planted at 5x5m planting distance and pruned in the Central Leader system in the experimental area located at Çukurova University Pozantı Agricultural Research and Application Center at an altitude of 1200m in the 2022-2023 period. In the study; 0.5% CaCl_2 , 300ppm Green Stim, 100ppm Chitosan, 400ppm Thyme oil and water were used as control. The study was carried out according to the randomized block trial design with 3 replications and 10 plants in each replication.

Plant Material

0900 Ziraat cherry variety, which is mid resistant to cracking, is known as Turkish Cherry in Europe. Fruit characteristics; colour is bright dark red and large and heart-shaped fruits are resistant to transportation and storage. It has a thin, long and green stem, and its flesh is hard, juicy and delicious; with these features, it is among the best cherries in the world (Demirtaş and Sarısu, 2011).

It is in the Bigarreau group. It ripens late. Its fruit is very large (8.15 g), wide heart-shaped and bright dark red, fruit flesh is quite hard, crisp, juicy and very delicious; quality is excellent but needs pollinator, resistant to bacterial cancer and its flowering time is quite late. Its net mesocarp ratio is 14.31 and it is resistant to transport (Anonymous 2010).

Applications to Prevent Cracking in Fruits and Increase Quality

The plant growth regulators used in the study are given below. Water application was used as a control.

- 1- Calcium chloride (CaCl_2)
- 2- Calcium chloride (CaCl_2) + Green Stim
- 3- Calcium chloride (CaCl_2) + Chitosan
- 4- Calcium chloride (CaCl_2) + Thyme oil

Calcium chloride (CaCl_2)

It is an inorganic compound, a salt with the chemical formula CaCl_2 . It is a white crystalline solid at room temperature and is quite soluble in water. It can be formed by neutralizing hydrochloric acid with calcium hydroxide. Calcium chloride is commonly found as a hydrated solid with $\text{CaCl}_2 \cdot n \text{H}_2\text{O}$. These compounds are mainly used for deicing and dust control. Since anhydrous salt is hygroscopic and liquid, it is used as a desiccant (Kemp and Keegan, 2000). In calcium applications, calcium makes the cell wall resistant to pressure and cracking as a result of blocking cell wall pectin's (Alani, 1980).

The main purpose taken into consideration in the selection of chemicals applied to reduce cracking is to reduce the amount of rainwater entering the fruit surface as much as possible during and after heavy rain. In many areas, calcium-containing solutions and the use of calcium together with substances such as copper, sulfate, nitrate, as well as antitranspirants and various surface waxes are used against fruit cracking (Sekse, 1995).

Green Stim

It contains natural osmotic pressure balancers (glycine, betaine) (Imrak, 2019).

Chitosan

Chitosan is obtained as a result of deacetylation of chitin in an alkaline environment. It is insoluble in water and organic-based solvents (Abdou et al., 2008). Chitosan, the most widely used polysaccharide, is an economical natural biopolymer obtained from sea shells. (Sandford, 1989).

Thyme Oil

In our country, there are many fragrant plant species known as "Thyme" belonging to the Lamiaceae family, and their essential oils especially contain carvacrol and thymol. Studies have determined that Thyme oil suppresses many fungal diseases (Baydar, 2007; Bosquez et al., 2010; Camele et al., 2012).

General Characteristics of the Research Area

The research was carried out in the experimental area of Ç.Ü. Pozantı Agricultural Research Center in Pozantı, which is 1200 meters above sea level. Coordinate: 37.480050,34.903235.

The study was conducted between 2022-2023 and was set up in a randomized plot design with 3 replications and 10 trees in each replication. All applications were made approximately 30 days before harvest when the fruits turned from yellow to pink (vein fall) with a 15-liter backpack pump to wet the entire tree. The applications and their doses are given in detail in Table 1. All spray treatments were applied when the fruit color turns from green to yellow (22.06.2022)

Table 1. Applications and doses

Applications	Doses
Control	Water
CaCl_2	%0.5
CaCl_2 + Chitosan	%0.5 CaCl_2 + Chitosan 100 ppm
CaCl_2 + Thyme Oil	%0.5 CaCl_2 + Thyme Oil 400 ppm

CaCl ₂ + Green Stim	%0.5 CaCl ₂ + Green Stim 300 ppm

Phenological Observations

Budbreak, full bloom and harvesting dates were recorded (Westwood, 1987).

Pomological Analyses

Pomological analyses were performed with 3 repetitions and on 10 fruits at harvest maturity in each repetition (Emerce, 2004; İmrak, 2019).

Average Fruit Weight (g): The fruits obtained were weighed with a scale with a sensitivity of 0.01 g and calculated by dividing the total weight by the number of fruits. Here, 30 randomly taken fruit samples that could represent the analyzed variety were divided into 3, with 10 fruits in each repetition, and these fruits were weighed individually to determine the average fruit weight of each repetition.

The fruits obtained were measured with a caliper with a sensitivity of 0.01 mm and calculated by dividing the total value by the number of fruits. fruit length (mm), fruit width (mm), fruit height (mm)

Total Soluble Solids (TSS) %: The percentage value of the samples taken from the fruit juice was measured with a hand refractometer.

Total Acidity (%): After completing 5 ml of fruit juice with distilled pure water to 100 ml, titratable 0.1 Normality NaOH (Sodium Hydroxide) will be added to 5 ml of fruit juice completed with distilled water to 100 ml with the help of a pH meter until the digital display on the pH meter reaches 8.00-8.10 and then calculated in terms of citric acid according to the formula below.

Acidity Formula = Amount of NaOH consumed x 20 x Factor (0.963) x Acid value (Acid value for citric acid, 0.0067).

Fruit Flesh Firmness (kg): The hardness of the fruits of the varieties in the trial was measured using a hand penetrometer.

Color Measurements

Color measurements made according to the C.I.E. L*a*b* system were carried out with a Minolta color measuring device. In this system, the a* value indicates the color change from green to red, and the b* value indicates the color change from blue to yellow. Positive values of a* indicate red, and negative values indicate green. Positive values of b* indicate yellow, and negative values indicate blue (İmrak et al., 2018). The data obtained from the experiment were analyzed using the JMP v.8 statistical package program and the averages were compared using the Tukey test.

Cracking Index

The cracking index will be calculated in order to determine the cracking prevention or reduction effects of the applications (Bilginer et al., 1999). In this method, cherries that reached harvest maturity were collected in the morning hours (09:00-11:00) and brought to the laboratory for analysis in the cold chain.

In order to measure the cracking resistance of cherries, 50 fruits randomly selected from the fruits located 1.5 m above the ground in the outward facing area of the trees were used. In this method, cherries that reached harvest maturity were collected before noon and brought to the

laboratory for analysis in the cold chain. In order to measure the resistance of cherries to cracking, 50 randomly selected fruits were placed in 2-liter glass jars and kept in pure water at 20°C for 2-4-6 hours. At 2-hour intervals, the fruits were removed from the water and the cracked fruits were counted, and the healthy fruits were put back into the water. The same procedures were performed after 4 and 6 hours. The obtained data were calculated according to the cracking index formula used by Bilginer et al (1999) for cherries and explained below.

$$\text{Cracking index} = (5a + 3b + c) \times 100/250$$

Statistical Analysis

The experiment was based on randomized blocking pattern as 3 replications and was assigned as one tree at each replication. The data were statistically analyzed using the Statistical Package for the. Means separation was determined by LSD test. Statistical analyses were carried out using JMP 5.0.1 version.

RESULTS AND DISCUSSION

It was observed that the applications made did not have any effect on the phenological stages. Phenological periods are presented in Table 2. It was determined that the dates specified in terms of phenological periods were parallel to previous studies and were found to be compatible with (İmrak and Küden, 2023).

Table 2. The effects of Applications on phenological stages in ‘0900 Ziraat’ sweet cherry variety

Variety	Dormancy Breaking	Full Bloom	Harvesting time
0900 Ziraat	15.02.2023	19.04.2023	21.06.2023

Among the applications applied to the 0900 Ziraat cherry variety included in the experiment, the highest fruit flesh hardness was determined as 5.42 kg in the Thyme oil application, while the lowest fruit flesh hardness was determined as 4.5 kg in the control application. The fruit flesh hardness obtained as a result of other applications is between these values. Thyme oil application provided the highest fruit flesh hardness and clearly distinguished itself from all other applications. Thyme oil is known to have strong antimicrobial and antifungal properties among vegetable oils and can provide a protective effect on fruit tissue. This result supports the effectiveness of thyme oil in increasing fruit quality. There are findings in the literature that thyme oil applications provide similar positive effects in other fruit species (Sivakumar and Bautista-Baños, 2014). Chitosan application also showed a significant effect on fruit flesh hardness. With 4.83 kg fruit flesh hardness, chitosan application provided a significant increase compared to the control group. Chitosan is a natural biopolymer that can prevent water loss and microbial infections by forming a protective layer on the fruit surface. This shows that chitosan is an effective agent in improving fruit quality. Similarly, chitosan applications have been reported to increase fruit flesh firmness in other fruit species (El Ghaouth et al., 1992; Bautista-Baños et al., 2006). Calcium chloride application increased fruit flesh firmness to 4.65 kg. Calcium may increase fruit firmness by contributing to the strengthening of cell walls and the increase in the water retention capacity of cells. This finding is consistent with the literature showing that calcium applications provide similar effects in other fruit species (Conway et al., 1994; Saure, 2005) (Table 3).

The lowest L* value found in color measurement was determined to be 19.61 for Thyme oil application, while the highest L* value was determined to be 26.78 for Chitosan application (Table 3). The lowest a* value was determined to be 14.03 for Thyme oil application, while the highest a* value was determined to be 23.96 for control application. In addition, the lowest b* value was

determined to be 5.06 for Thyme oil application, while the highest b^* value was determined to be 9.23 for control application.

Among the applications applied to the 0900 Ziraat cherry variety in the trial, the highest fruit weight was determined as 8.42 g in the Thyme Oil application, while the lowest fruit weight was determined as 7.39 g in the control. When we look at the average fruit weight data of all applications and control groups, it was determined that the average fruit weight of the Thyme Oil was higher (Table 4). The lowest SÇKM amount measurement value of the applications was measured as 14.63 in Green Stim, while the highest value was determined as 15.33 in Chitosan. In the pH value measurements of the applications in the trial, the lowest value was measured in the Calcium application as 2.88. The highest value was measured in Green Stim as 2.94. It was determined that the pH value of all applications and control groups was the highest and the lowest was in the Calcium application.

Table 3. The effects of Applications on fruit firmness and colour characteristics in '0900 Ziraat' sweet cherry variety

Applications	Fruit Firmness (kg)	L*	a*	b*
Control	4,5d	23,29ab	23,96a	7,01
CaCl ₂	4,65c	20,44ab	17,21ab	6,06
CaCl ₂ + Chitosan	4,83b	26,78a	17,38ab	6,47
CaCl ₂ + Green Stim	4,53bc	24,8b	17,39ab	6,07
CaCl ₂ + Thyme Oil	5,42a	19,61b	14,03b	5,06
Lsd _{%5}	0,20	5,47	5,42	ns

The Calcium application provided the lowest pH value (2.88) and was significantly different from all other applications and the control group. The potential of calcium to reduce fruit pH may be due to the interaction of calcium ions with cell walls and intracellular matrices and increasing acidic properties. Similar findings have been reported in the literature that calcium applications improve product quality by reducing fruit pH (Conway et al., 1994; Saure, 2005).

The control group and chitosan application showed similar results with a pH value of 2.92. Chitosan can maintain pH balance by forming a protective layer on the fruit surface with its biopolymer structure. There are findings in the literature that chitosan improves fruit quality and provides pH balance (El Ghaouth et al., 1992; Bautista-Banos et al., 2006). Oregano oil application showed a result close to other applications with a pH value of 2.93. The antimicrobial and antifungal properties of oregano oil can help maintain pH balance by reducing microbial activity on the fruit surface. Similar findings on the positive effects of oregano oil applications on fruit quality are also available in the literature (Sivakumar and Bautista-Banos, 2014) (Table 4).

Table 4. The effects of Applications on pomological characteristics in '0900 Ziraat' sweet cherry variety

Applications	Average fruit weight (g)	Total soluble solid content TSS (%)	Titrate acidity (TA) (g citric acid/100 ml)

Control	7,39b	14,93	2,92ab
CaCl ₂	7,97ab	15,23	2,88b
CaCl ₂ + Chitosan	7,89ab	15,33	2,92ab
CaCl ₂ + Green Stim	7,97ab	14,63	2,94a
CaCl ₂ + Thyme Oil	8,42a	15,17	2,93ab
Lsd _{%5}	0,77	ns	0,09

In the control group, the fruit cracking rate was determined to be the highest at 11.2%. This shows that a significant portion of the cherry fruits cracked when no application was made. 0.5% Calcium Chloride (CaCl₂) application reduced the fruit cracking rate to 2.4%. This shows that CaCl₂ significantly reduces fruit cracking. 300 ppm Green Stim application reduced the fruit cracking rate to 0.8%. This shows that Green Stim greatly reduces fruit cracking and is an effective application. 100 ppm Chitosan application also reduced the fruit cracking rate to 0.8%. This shows that chitosan is effective in reducing fruit cracking. 400 ppm Thyme Oil application achieved the lowest fruit cracking rate of 0.4%. This shows that thyme oil is the most effective application in preventing fruit cracking (Figure 3)

Figure 3. Effects of different treatments on 0900 Ziraat cherry fruit cracking Index

CONCLUSIONS

The results of this study have shown that all treatments significantly decreased the cracked fruit ratio compared to the control. But Thyme oil applications especially reduced the amount of 68.98 percent. In this study on 0900 Cherry, Thyme oil found to be the most effective Applications. It was followed by Green Stim, There were no detected any big differences Phenological and pomological (Except fruit weight) observations. Thus, Thyme oil gave the best result for reducing fruit cracking and Green Stim, Chitosan, CaCl₂ gave recommendable results compared to the control in 0900 Ziraat cherry cultivar in excessive rainfall years.

ABSTRACT

The microbiota in the colon transforms polysaccharides such as pectin and xanthan gum and contributes to the maintenance of colon health by providing the formation of short-chain fatty acids. Various studies have shown that microbiota breaks down these components and form short-chain fatty acids, gas, and various metabolites, but in studies, the microbiota has generally been examined as a community, and the contribution of different bacterial species to biotransformation has not been sufficiently demonstrated. This study investigated whether *Escherichia coli* strains isolated from the human colon, which has not been studied before, produce short-chain fatty acids using pectin or xanthan gum in vitro. The results showed that when cultures containing different concentrations of polysaccharides were compared with control cultures (without polysaccharides), the lowest pH values were observed in cultures containing 5 mg/ml xanthan gum and 10 mg/ml pectin. However, gel formation was observed in the media prepared at these concentrations, and problems were experienced during the pipetting stages. For these reasons, 2 mg/ml xanthan gum and 5 mg/ml pectin concentrations were selected to test the production of short-chain fatty acids. The results of this study showed that these strains could not produce short-chain fatty acids under the conditions examined, but it aims to examine different bacterial strains in further studies.

Keywords: pectin, xanthan gum, microbiota, *E. coli*, short-chain fatty acids

INTRODUCTION

The human digestive system harbors a complex and dynamic population of microorganisms called the gut microbiota. This population of microorganisms includes bacteria, archaea, eukaryotes, and viruses (Koppel and Balskus, 2016). This population is larger than the number of human body cells, and it is estimated that there are at least 100 trillion (10^{14}) microorganism cells in the human gut (Clemente et al., 2012). The gut microbiota has a significant effect on the health and disease status of the host. The microbiota benefits the host by performing physiological functions such as strengthening intestinal integrity, shaping intestinal epithelial cells, obtaining energy, protecting against pathogens, and strengthening the host's immunity. Disturbance of the balance of the gut microbiota (dysbiosis) has been associated with the pathogenicity of many inflammatory diseases and infections (Thursby and Judge, 2017). The composition of the gut microbiota varies significantly among individuals. It is affected by many factors such as genetics, host physiology (age, disease, stress, etc.), medications used, diet, and living environment (Holscher, 2017). Although studies on the presence of microorganisms in placenta have been published in recent years (Aagard et al., 2014; Rodriguez et al., 2015), the common belief is that the intestinal microbiota begins to form at birth (Thursby and Judge, 2017). It is also known that antibiotic use in adulthood causes changes in the composition of the intestinal microbiota and that these changes can be long-term (Modi et al., 2014).

Diet is one of the important factors affecting the intestinal microbiota. There are many published studies, which indicates the influence of diet on microbiota. For instance, when the

microbiota of people in a hunter-gatherer society in Tanzania was compared with those of people on a Western-style diet, it was found that the microbiota richness and diversity were higher in hunter-gatherers. This was associated with the fact that the diet of hunter-gatherers, unlike Western societies, included more carbohydrates that can be degraded by the microbiota (Schnorr et al., 2014). It is known that each of the macronutrients (fat, protein, carbohydrates) and many micronutrients can change the intestinal microbiota. The most prominent macronutrient among these is carbohydrates. For example, in a study examining fructose alone, it was found that it changed the composition of the intestinal microbiota (Mastrocola et al., 2018). An animal model study examining sucrose as part of a Western-style high-fat, high-sugar diet, it was observed that the microbiota was rapidly restructured (Collins et al., 2016). Furthermore, nutrients that humans cannot digest are used by bacteria in the large intestine in their basic biological processes. Therefore, changes in the human diet also affect the metabolism of these bacteria.

According to the Codex Alimentarius Commission (CAC) definition, dietary fiber is defined as carbohydrate polymers that are composed of 10 or more monomers and cannot be digested and absorbed in the human small intestine and is examined in 3 categories. These are classified as; edible carbohydrate polymers naturally found in foods; edible carbohydrate polymers obtained from raw food materials by physical, enzymatic or chemical means and having beneficial physiological effects based on scientific evidence; and finally, edible synthetic carbohydrate polymers having beneficial physiological effects based on scientific evidence. However, the definition of how many monomers dietary fiber will consist of may vary from country to country (Holsher, 2017). Dietary fibers can be obtained from plant and microbial sources. The main dietary fibers can be listed as: Cellulose, hemicellulose, guar gum, xanthan gum, alginate, carrageenan pectin, etc. (Guillon et al., 2011). These dietary fibers are broken down by intestinal bacteria when they reach the large intestine. As a result, they affect the stool mass, stool frequency, colon pH, and the energy obtained from these indigestible dietary fibers in individuals. However, the type of dietary fiber is broken down is important in terms of the metabolites formed (Guillon et al., 2011).

Epidemiological studies have shown that there is an inverse relationship between dietary fiber intake and cardiovascular diseases. The main important products formed as a result of the fermentation of these dietary fibers in the large intestine are short-chain fatty acids. The main short-chain fatty acids are acetate, propionate, and butyrate. Short-chain fatty acids play an important role in the health of the host. Butyrate contributes to the integrity of the intestinal barrier in the large and small intestines and provides energy to the epithelial cells in the large intestine (Chambers et al., 2018). In addition, studies have shown that butyrate has an inhibitory effect on colon cancer and the development of tumors. Different dietary fibers are formed with a wide variety of monosaccharide bonds. Although the human digestive system is inadequate in breaking down these bonds, the intestinal microbiota, with its diversity and gene pool, contains enzymes that can break down these bonds and can use unbreakable complex carbohydrates as an energy source (Gentile and Weir, 2018). Nutrition is one of the most important factors that shape and change the intestinal microbiota throughout human life. In addition, it is also a fact that the intestinal microbiota changes or transforms the foods consumed and the components in these foods. In this sense, the intestinal microbiota is one of the most important links in this bioavailability chain.

Pectin is one of the structural polysaccharides of plants and has a structure consisting of a polygalacturonic acid chain (Vandamme et al., 2002). It has a wide usage rate in the food industry due to its gelling, thickening and stabilizing properties. Since pectin can also be considered in the oligosaccharide class, it can also be fermented by intestinal bacteria (Willats et al., 2006). However, the rate of use by bacteria varies depending on the chemical structure and methylation degree of pectin (Hamaker et al., 2014). In some studies, it has been reported that pectic fractions support the development of bacteria such as *Bifidobacterium* and *Lactobacillus*, although it depends on the composition and prebiotic index of pectin. Thus, its benefits in protecting intestinal health and increasing digestion have been observed (Wicker et al., 2014). Gulfi and his colleagues

(2007) determined that total short-chain fatty acid production was high as a result of fermenting pectin, which was extracted from apples and has a branched structure, with bacteria in human feces. In a study conducted with mice, Fåk and his colleagues (2015) observed that pectin increased the level of short-chain fatty acids in the cecum and blood, and stated that acetic acid production was low in low-methylation pectins.

Xanthan gum is a microbial polysaccharide produced by *Xanthomonas campestris*, which is widely used as a thickener and stabilizer in food, pharmaceutical and agricultural applications (Rosalam and England, 2006). Since it is soluble in hot and cold water, it is used in many products in the food industry, and in the pharmaceutical industry, it is also used as a coating material with other polysaccharides such as chitosan (Giavasis, 2013). Xanthan gum, which is considered among the digestible carbohydrates, is also called dietary fiber and its use by intestinal bacteria was also investigated. In a study conducted by Bourquin et al., in vitro fermentation of various dietary fibers with bacteria isolated from feces was investigated, and they found that intestinal bacteria fermented xanthan and could produce high levels of acetic acid (Bourquin et al., 1996). Additionally, Schnizlein et al. (2020) found that in mice fed a diet supplemented with xanthan gum, the production of short-chain fatty acids increased and the efficacy of an antibiotic used to prevent colonization by *Colostroides difficile* bacteria was enhanced.

Studies showed that dysbiosis has been linked with many diseases. Various approaches, such as probiotics, prebiotic supplements, or fecal microbiota transplantation, have been intensively studied to cure the gut microbiota imbalance. Restoration of the levels of short-chain fatty acids is another therapeutic approach to cure dysbiosis (Fusco et al., 2023). Studies where the human microbiota was examined cumulatively showed that microbiota can degrade pectin and xanthan gum and can form acetate, propionate, and butyrate in different proportions. What has not been fully revealed in these studies and is worth examining is the contribution of individual members of the microbiota to this transformation. *Escherichia coli* is a bacterium commonly found in the human intestine. Previous studies have shown that *E. coli* strains can degrade different glucosides thanks to their different Glucosyl Hydrolase (GH) enzymes. In this context, this study investigated whether 2 different *E. coli* strains isolated from the human intestine can degrade pectin and xanthan gum and form short-chain fatty acids in vitro.

MATERIAL AND METHOD

E. coli strains used in the study were obtained from Karadeniz Technical University, Faculty of Medicine, Department of Microbiology. Nutrient Broth (Oxoid) was used to develop *E. coli* strains. After the liquid medium was prepared, the pH was adjusted to 6.8 ± 0.2 . Pectin (pectin from Citrus peel, Galacturonic acid ≥ 74.0) and xanthan gum (Xanthan from *Xanthomonas campestris*) used in the analyses were obtained from Sigma Aldrich.

The effect of different pectin and xanthan gum concentrations on the growth of *E. coli* strains were tested in the medium, 50 ml containing different concentrations of pectin (1, 2.5, 5, 10 mg/ml) and xanthan gum (0.5, 1, 2, 5 mg/ml). The media were inoculated with fresh *E. coli* F or *E. coli* C cultures and incubated for 8 hours in a shaking incubator (Heidolph, Germany) at 37°C. At the end of the incubation period, microbial growth in the cultures was determined by OD600 measurements made with a spectrophotometer (Thermo Scientific, Multiskan GO, US). The controls without pectin or xanthan gum were also prepared.

After determining the appropriate pectin and xanthan gum concentration, 50 ml media were prepared for each *E. coli* strain. These media were inoculated with fresh *E. coli* F or *E. coli* C cultures and incubated for 24 hours in a shaking incubator (Heidolph, Germany) at 37°C. At the end of the incubation period, pH measurements of the cultures were also made. In addition, fresh cultures of *E. coli* F and *E. coli* C were inoculated together on media containing pectin or xanthan gum (3 parallels, 50 ml medium). These media were incubated for 24 hours in a shaking incubator (Heidolph, Germany) at 37°C, and pH measurements were made at the end of the incubation

period. After the prepared cultures were transferred to clean falcon tubes, they were stored at -20°C until analyzed.

GC-MS analysis was performed using the method Schneider et al. used (2006) with modifications. 0.4 ml of 50% sulfuric acid and 2 ml of diethyl ether were added to a sufficient amount (2 ml) of culture; the sample was mixed in an orbital shaker for 45 minutes and then centrifuged at 3000 rpm for 5 minutes. Potassium persulfate was added to remove the remaining water and injected into the device. Shimadzu GC-MS QP2010 Ultra and DB-FastFAME 30 m, 0.25 mm, 0.25 µm (Agilent, US) columns were used in the analyses. The temperature program was programmed to increase from 100°C to 240°C and lasted for a total of 20 minutes. The split ratio was 10:1, the injection volume was 1 µl, the solvent delay time was 0, He was selected as the carrier gas, and the flow was adjusted to 1 ml/min. He was set to 30 ml/min, H2 flow to 40 ml/min, and dry air flow to 400 ml/min. The external standard method was used to quantify the samples; acetic acid, butyric acid, and propionic acid standards were run in the device at different concentrations (5, 10, 12.5, 25, 50 mol/l), and their retention times in the column were determined.

RESULTS AND DISCUSSION

Initially, each medium's pH values varied between 6.70-6.98. After the incubation, no pH below these values was observed in any culture. The samples were compared with control cultures to determine the pH decrease due to short-chain fatty acids that may occur due to *E. coli* activity during the incubation process. When the control cultures (without polysaccharides) were compared with the cultures containing different concentrations of polysaccharides at the end of the incubation, it was observed that the lowest pH values were generally in cultures containing 5 mg/ml xanthan gum and 10 mg/ml pectin (except 10 mg/ml for *E. coli* F). Gel formation was observed in the media prepared at these concentrations, and problems were experienced during the pipetting stages. For these reasons, 2 mg/ml xanthan gum and 5 mg/ml pectin concentrations were selected to test the production of short-chain fatty acids.

The retention times determined for these standards are as follows: Acetic acid; 3.2 min, propionic acid; 4.1 min, butyric acid; 5.5 min. These short-chain fatty acids were not detected in any of the examined samples. Noise peaks were observed in the GC-MS chromatograms of the samples; a sample chromatogram is shown in Figure 1.

Figure 1. GC-MS chromatogram

CONCLUSIONS

Although there is no definitive information in the literature that *E. coli* can break down pectin or xanthan gum, it has been found that D-galacturonic acid units, which are monomers of pectic components, are broken down by *E. coli* in a unique way (Richard and Hilditch, 2009), and some previous studies have shown that some bacteria members of the Enterobacteriaceae family can break down pectin with their own enzymes (Abbott and Boraston, 2008). The fact that *E. coli* is an important member of the human intestinal microbiota and has strains that can be both pathogenic and probiotic makes this bacterium significant. Therefore, although the existing *E. coli* strains were tested for short-chain fatty acid production in the first step, our aim is to identify new bacterial strains that can produce short-chain fatty acids in the human intestine. In future studies, it is aimed to isolate bacteria that can use these polysaccharides and test the production of short-chain fatty acids in these strains by culturing them in media where pectin or xanthan gum is used as the sole carbon source from human feces solution.

ABSTRACT

Snapdragon (*Antirrhinum majus* L.) flower has unique inflorescence, attractive colors, and shapes, and is known as a cut flower in the world flower market, however, it is considered a sensitive flower to ethylene. Ethylene hormone plays an important role in the senescence of ethylene-sensitive flowers, especially snapdragon flowers, and causes the stem bending of cut flowers. This complication greatly reduces the ornamental value of snapdragon flowers and causes economic damage to producers and consumers. This study investigated different levels of ethylene hormone (0, 1, 10, and 100 $\mu\text{l. L}^{-1}$) on some growth characteristics and postharvest vase life of snapdragon flowers. The first visible response of snapdragon cut flowers to ethylene treatment was florets dropping whereas the flowers were turgid. The florets dropping was observed in all three levels of ethylene and indicated a significant difference with the control treatment. Ethylene also caused a disturbance in water absorption. Consequently, the relative water content, fresh weight, protein content, and vase life decreased. The curvature angle was also maximum at 100 $\mu\text{l. L}^{-1}$ ethylene.

Keywords: *Antirrhinum majus* L, Curvature angle, Fresh weight, Post-harvest, Senescence

INTRODUCTION

The Snapdragon plant, scientifically known as *Antirrhinum majus* L., is a well-liked decorative plant appreciated for its attractive and aromatic blooms. In the United States, the sales revenue from freshly-cut snapdragons amounted to \$12.18 million in 2015, positioning it among the top ten fresh-cut flowers. Challenges arise in the postharvest stage due to the plant's vulnerability to ethylene, which triggers florets' abscission and wilting. This sensitivity contributes to issues like limited vase life, incomplete flower opening, suppression of pigmentation, and stem curvature, impacting snapdragons' overall production and market performance (Kato et al., 2022; Xiang et al., 2020).

Snapdragon petals undergo abscission upon ethylene exposure, suggesting the sensitivity of snapdragon flowers to ethylene. Ethylene is recognized for its pivotal regulatory functions across diverse plant species. The biological activity of ethylene is evident even at very low concentrations ranging from 0.01 to 1.0 parts per million (ppm) (Heffron and Korban, 2022; Kato et al., 2022).

The longevity of cut snapdragon flowers is typically dictated by stem bending, as flowers with bent stems are unsuitable for commercial use. Regrettably, stem bending frequently manifests in snapdragon cut flowers within a brief period of vase life, making it a significant postharvest challenge (Naing et al., 2021). Research using ethylene and ethylene-action inhibitors like silver thiosulfate (STS) and 1-methylcyclopropene (1-MCP) has aimed to determine the involvement of ethylene as a positive regulator in snapdragon stem-bending. However, results varied, with some studies showing no significant impact on bending with STS or 1-MCP, while others reported a

blocking effect, suggesting further research is needed to clarify ethylene's role in this mechanism (Çelikel et al., 2010; Naing et al., 2021; Woltering, 2016).

In the present study, we treated snapdragon cut flowers with ethylene and investigated the influence of ethylene on various vase-life characteristics of snapdragon, such as curvature angle and florets abscission.

MATERIAL AND METHOD

Snapdragon F1 (*Antirrhinum majus* 'Legend White') seeds were germinated in Petri dishes under controlled conditions and placed in a greenhouse with regulated temperature and natural light. The plants were watered every other day until they reached the flowering stage, at which point they were moved to a growth chamber for ethylene treatment. Snapdragon flowers were trimmed to 40 cm and then treated with ethylene at 1, 10, and 100 $\mu\text{l l}^{-1}$ for 48 h at 22 °C (each treatment with 10 repetitions). The treatment was performed in 38.8 × 39.0 × 38.8 cm glass chambers. The KOH solution (1 M) was placed inside the chamber to reduce CO₂ concentration (Chamani et al., 2005).

The cut stems were weighed on day 0 (before treatment), day 1 (1 day after treatment), day 3 (3 days after treatment), day 5 (5 days after treatment), day 7 (7 days after treatment), day 9 (9 days after treatment), and day 11 (11 days after treatment). The water absorption was also recorded at these time points. The floret's abscission was counted on day 1.

Vase life was determined by recording the number of days from treatment initiation (day 0) until 50% of the flowers in the spike began wilting or drying, indicating the end of their commercial viability. Soluble protein content in the petals was measured using the Bradford assay method to quantify the total protein content (Bradford, 1976) on day 1. Stem curvature in snapdragon cut flowers was measured using a protractor and stated in degrees on day 11. A straight stem was defined 0°.

Statistical analysis of the data was conducted using SPSS V16 software, with significance levels determined through Duncan's multiple range test at a 5% probability.

RESULTS AND DISCUSSION

Gradually, the weight of the shoot in the control increased with a gentle slope and decreased after 5 days. On the other hand, ethylene treatment (1, 10, and 100 $\mu\text{l L}^{-1}$) caused a significant decrease in shoot weight 1 day after the treatment. With increasing ethylene concentration, weight loss occurred at a faster rate (Figure 2A). According to the changes in shoot weight, water absorption also revealed a significant increase in the control. Concentrations of 10 $\mu\text{l L}^{-1}$ and 100 $\mu\text{l L}^{-1}$ prevented water absorption in flower stems and as a result, the weight of the shoots decreased (Figure 2B). The treatment of cut snapdragon flowers with ethylene (10>100>1 $\mu\text{l L}^{-1}$) caused the florets to drop severely. The lowest drop of florets was observed in the control (Figure 2C). As a result, the vase life of untreated flowers was recorded up to 8 days (Figure 2D). Ethylene also caused a significant decrease in total soluble protein content, which indicated the rapid degradation of proteins under ethylene treatment (Figure 2E). Furthermore, the degree of stem curvature observed in E10 and E100 treatments was significantly higher than those of the E1 and control treatments at 11 days after treatment (Figure 2F).

Figure 1. Comparison of the effects of different concentrations of ethylene on postharvest quality of snapdragon cut flowers. (A): control ($0 \mu\text{l. L}^{-1}$), (B): E1 ($1 \mu\text{l. L}^{-1}$), (C): E10 ($10 \mu\text{l. L}^{-1}$), (D): E100 ($100 \mu\text{l. L}^{-1}$). The photos were taken at day 5.

Figure 2. Some post-harvest characteristics of cut snapdragon flowers under ethylene treatment (0 $\mu\text{L L}^{-1}$, Control; 1 $\mu\text{L L}^{-1}$, E1; 10 $\mu\text{L L}^{-1}$, E10; 100 $\mu\text{L L}^{-1}$, E100). (A): shoot weight, (B): water absorption, (C): florets dropping, (D): vase life, (E): total soluble protein, (F): curvature angle. Different letters indicate significant differences at $p \leq 0.05$ (Duncan's test). Error bars represent $\pm\text{SD}$, $n=10$.

In this study, we investigated the effect of different concentrations of ethylene on some characteristics of snapdragon flower post-harvest. This study indicated that increasing the concentration of ethylene can strongly increase the angle of curvature and bending of the stem. This incident was accompanied by a decrease in the weight of the stem, a decrease in water absorption, severe dropping of florets, and a lack of soluble protein, which ultimately led to the loss of the useful vase life of the cut flower.

Ethylene can stimulate many degenerative processes in cut flowers (Lukaszewska, 1985). In the present study, different concentrations of ethylene decreased total protein content. Proteins, as vital cellular components, are severely sensitive to adverse environmental conditions. The decrease in total protein is attributed to the involvement of ethylene in the expression of genes related to

aging, activation of plant proteases, and proteolytic degradation (Chamani et al., 2007; Eason et al., 2002; Jones et al., 2005).

Many studies have been done on the effect of ethylene regulation on stem bending. However, the results are contradictory and it is not yet clear whether ethylene stimulates stem bending or not (Naing et al., 2021). In a study, the treatment of cut tulip stems with ethephon (ethylene-releasing compound) caused a delay in stem bending (Van Doorn et al., 2011). On the other hand, in some species such as *Calendula officinalis* and gerbera, ethylene inhibiting compounds have reduced the rate of stem bending, which depends on the structural nature of the stems of different species (Hemati et al., 2019; Lone et al., 2021; Naing et al., 2021).

CONCLUSIONS

This study revealed that the initial observable reaction of snapdragon cut flowers to ethylene exposure was the dropping of florets (in the turgid condition). This phenomenon was evident across all levels of ethylene, highlighting a notable contrast with the control group. Furthermore, ethylene led to a disruption in water uptake, resulting in reductions in relative water content, fresh weight, protein levels, and vase longevity. The highest curvature angle was recorded at an ethylene concentration of 100 $\mu\text{l. L}^{-1}$ and had a significant difference with control.

ABSTRACT

Global climate change imposes increasing and multifaceted pressures on soil health and fertility. Rising temperatures, irregular precipitation patterns, and the accumulation of greenhouse gases in the atmosphere significantly affect the physical, chemical, and biological properties of soils. Elevated temperatures accelerate the decomposition of soil organic matter, reduce soil organic carbon, and increase the risk of salinization and erosion. Intense and erratic rainfall events disrupt soil aggregate stability, lower cation exchange capacity, and enhance nutrient leaching. Conversely, reduced rainfall and drought limit soil moisture availability and nutrient uptake, while suppressing biological nitrogen fixation. Although increased atmospheric CO₂ levels may stimulate microbial activity and nutrient cycling, they can also lead to net carbon losses from the soil. This review explores the complex effects of climate change on soil health, focusing on structural degradation, shifts in pH, salinization, nutrient cycling disruptions, and microbial imbalance. Furthermore, the study discusses mitigation and adaptation strategies (such as conservation agriculture, organic matter management, and integrated nutrient management) that can help reduce climate-related soil degradation. Implementing climate-resilient soil management practices is essential to sustain long-term soil health and agricultural productivity.

Keywords: Climate change, Greenhouse gases, Carbon cycle, Sustainable agriculture

INTRODUCTION

Soils underpin terrestrial life and global food systems by regulating water and nutrient cycles, storing vast amounts of carbon, and hosting extraordinarily diverse biota that drive decomposition and fertility. Soils contain more carbon than the atmosphere and terrestrial vegetation combined, positioning them as a critical yet vulnerable component of both the climate system and agricultural productivity. Recent studies and guidance from agricultural and climate agencies emphasize that the size and persistence of this soil carbon pool confer both opportunity and risk: management can enhance sequestration, but warming and land-use pressures can accelerate losses (Keller and Handler 2024). Anthropogenic climate change, which has resulted in approximately 1.1 °C of global warming relative to the 1850–1900 baseline, has already led to widespread and multifaceted impacts on both natural and managed ecosystems. There is high confidence that continued warming will exacerbate risks to soil health and food security. The IPCC's Sixth Assessment Synthesis Report (2023) highlights that increasing temperatures, shifting precipitation regimes, and more frequent extremes are altering hydrologic and biogeochemical processes that determine soil health, with cascading effects on crop yields and rural livelihoods.

Warming directly influences the soil carbon balance by accelerating microbial metabolism and decomposition, potentially shifting soils from net sinks to net sources of CO₂ in sensitive

regions. Recent whole soil warming experiments and model data analyses published since 2023 highlight the significant vulnerability of soil organic carbon, including deeper soil layers that were previously considered relatively stable. These studies consistently report increased carbon emissions under sustained warming and underscore considerable uncertainty in both the magnitude and timing of these losses (Ren et al. 2024). Hydroclimatic change compounds these thermal effects. Intensifying heavy-precipitation events increase erosion, destabilize aggregates, and enhance nutrient leaching, while prolonged drought reduces soil moisture, suppresses biological nitrogen fixation, and impairs microbial functioning. Emerging assessments and regional projections show rising erosion risk under warmer, more variable climates, with implications for water quality and long-term soil fertility (Yin et al. 2025; Lua et al. 2024; IPCC 2023). At the farm and landscape scales, these physical and biogeochemical stresses translate into measurable risks for crop production. A 2023 article in *Nature Reviews Earth & Environment* notes that warmer temperatures, elevated CO₂, and altered water availability jointly modulate cereal yields, often exposing heat and water-stress thresholds that management must address. Complementary experimental evidence suggests that climate change and intensified cropland use can reduce soil multifunctionality, defined as the concurrent provision of nutrient cycling, carbon storage, and water regulation. This reduction in multifunctionality may, in turn, constrain agronomic resilience (Sünnemann et al. 2023)

Given soils' centrality to both mitigation (through carbon storage) and adaptation (through water retention, nutrient buffering, and biological resilience), safeguarding soil health is a prerequisite for maintaining agricultural productivity under climate change. This review synthesizes current understanding of how warming, altered precipitation, and rising atmospheric CO₂ interact to affect soil physical structure, chemistry (pH, salinity, cation exchange capacity), and biology (microbial communities and nutrient cycling). It also evaluates evidence based strategies such as conservation agriculture, organic matter management, and integrated nutrient management, which have the potential to slow or reverse climate related soil degradation while maintaining agricultural productivity.

CLIMATE CHANGE DRIVERS AFFECTING SOIL HEALTH

Rising temperatures

Global warming has led to significant increases in both air and soil temperatures, with profound implications for ecosystem processes and climate feedbacks. In China, analyses of five decades of temperature records (1962–2011) revealed that surface soil temperatures rose 31% more than air temperatures and that warming penetrated as deep as 3.2 meters, amplifying soil respiration rates by up to 28% and extending the growing season by approximately 20 days (Zhang et al. 2016). Similar long-term trends have been documented in other regions, such as North Rhine-Westphalia, Germany, where soil warming ranged from 0.36 °C to 0.47 °C per decade depending on depth (Dorau et al. 2022). Moreover, projections for the coming decades imply continued soil warming, especially in deeper layers, potentially altering global temperature regimes and cascading into ecological disruptions (Bradford 2019; Lembrechts 2022). Taken together, these findings highlight the increasingly urgent need to incorporate soil temperature dynamics, alongside atmospheric warming, into climate models and ecosystem assessments, as soil warming acts both as a driver and an amplifier of climate change.

Altered precipitation regimes

Global warming is profoundly altering precipitation regimes worldwide, intensifying both the wet and dry extremes and restructuring seasonal patterns. Rising global temperatures increase the atmosphere's capacity to hold moisture, by approximately 2 to 3 percent per degree Celsius on a global scale, with extreme precipitation events intensifying at an even faster rate. This results in more severe rainfall events and prolonged dry periods, even as average precipitation shows an overall increasing trend (Douville, 2021). Climate models reveal that precipitation becomes less frequent yet more intense in the tropics, with heavy precipitation events increasing by up to 35 % per 1°C warming, despite an overall decline in light rainfall (Guo *et al* 2022). Furthermore, the annual range of precipitation widens significantly; maximum precipitation increases by roughly 3.6 % °C⁻¹, while minimum precipitation rises by only 0.2 % °C⁻¹ (Guo *et al.* 2012). Changes in wet and dry season patterns are also evident: across the tropics, many regions are transitioning from annual to biannual precipitation regimes, with wet seasons shortening by an average of about 7 days and beginning 6 days later, while dry seasons grow both longer and drier (Guo *et al.* 2012). Moreover, projections suggest that large precipitation accumulations, which have been rare in historical records, will become exponentially more likely under continued warming, with some events projected to increase by several hundred to over one thousand percent (Neelin *et al.* 2017). Collectively, these alterations not only pose escalating risks for flooding, drought, and agricultural disruption but also challenge water-resource management and infrastructure resilience in both regional and global contexts.

Drought

Anthropogenic global warming is exacerbating drought globally through a combination of elevated atmospheric evaporative demand (AED), altered precipitation dynamics, and soil moisture depletion. Recent high-resolution global drought data (1901–2022) demonstrate that increased AED (driven by rising temperatures) has amplified drought severity by an average of 40 %, and has helped expand drought-affected land by approximately 74 % in the period 2018–2022 compared to 1981–2017, with nearly 30 % of the terrestrial surface experiencing moderate to extreme drought in 2022 alone, 42 % of which is attributable to AED (Gebrechorkos *et al.* 2025). This pattern is echoed regionally; in the Iberian Peninsula, intensified evaporative demand has led to more frequent and severe hydrological droughts, significantly reducing streamflow in both natural and regulated river basins (Lorenzo, 2014). Projections indicate that under moderate emissions scenarios (SSP2-4.5), by mid-century nearly 70 % of global land could face declining soil moisture, increasing agricultural drought risk particularly in regions like India, China, Europe, and the United States (OECD, 2025). Moreover, observational and modeling evidence indicates that drought durations, particularly the longest annual dry spells, may lengthen by the end of the century, substantially exceeding midrange estimates when models are calibrated with observational data. This convergence of rising temperatures, increased evaporation, and declining moisture storage highlights the urgent need for resilient water resource management to address more frequent, prolonged, and severe drought conditions.

Elevated atmospheric CO₂ (Eco₂)

Elevated atmospheric carbon dioxide, a central driver of anthropogenic climate change, exerts a fundamental influence on plant physiology, hydrology, and ecosystem carbon cycling. However, the magnitude and consistency of these effects remain highly dependent on environmental context. The dramatic rise in CO₂ from preindustrial ~280 ppm to over 427 ppm by 2024 underscores its critical role in enhancing the greenhouse effect and global warming (NOAA, 2024). On the positive side, Eco₂ enhances photosynthetic carbon uptake, thereby increasing terrestrial gross primary productivity (GPP) and improving leaf-level water-use efficiency by reducing stomatal conductance and transpiration (Lucas et al. 2019). Free Air Carbon Dioxide Enrichment (FACE) studies report biomass increases of approximately 20 to 30 percent, although these gains are often limited by soil nutrient availability, particularly nitrogen and phosphorus. These nutrient constraints account for a substantial portion of the variability observed in carbon fertilization responses (Fu et al. 2024). Additionally, elevated CO₂ can partially buffer plants against drought and heat stress by improving water status and mitigating oxidative damage, as seen in meta-analyses across diverse species and controlled experiments such as those involving *Arabidopsis* (Wang et al. 2022). That said, Eco₂ can also yield counterintuitive outcomes: enhanced leaf area may increase canopy transpiration, and changes in plant hydraulics (e.g., altered stomatal behavior or hydraulic conductance) may reduce drought resilience in certain contexts (Becklin et al. 2017). Moreover, the CO₂ fertilization effect may be waning globally due to nutrient constraints and ecosystem saturation, potentially weakening the land carbon sink and increasing reliance on mitigation strategies. Thus, although elevated carbon dioxide plays a critical role in modulating plant responses under climate change, its overall influence is determined by species-specific traits, environmental interactions, and resource availability. This underscores the need for nuanced, multifactor assessments in ecosystem modeling.

SOIL PROPERTY ALTERATIONS UNDER CLIMATE STRESS

The climate stress factors mentioned above reconfigure soils' physical, chemical, and biological properties in ways that directly govern fertility and yield stability.

Physical properties: structure, aggregation, and erosion susceptibility

Under climate stressors such as intensified precipitation, prolonged droughts, and fluctuating temperatures, soil physical properties undergo marked degradation. Elevated temperatures and extreme heat events can reduce cohesion among clay particles, shifting textures toward more silt-sized fractions and compromising structural integrity through induced cracking and dehydration of 2:1 clay minerals (Mangi et al. 2017). Drought exacerbates these effects by suppressing the production of root mucilage and microbial exudates that normally stabilize aggregates, leading to a decline in mean weight diameter (MWD) and aggregate stability; the removal of vegetation during drought further accelerates macroaggregate breakdown and diminishes aggregate-associated organic carbon (Reinsch et al. 2024). When heavy rainfall follows such weakened soil states, erosion susceptibility increases markedly: less aggregated soils, particularly coarser-textured ones, show higher erodibility and decreased stability across successive rainfall events, with significant reductions in soil K-factor observed (Yao 2019). Moreover, intensifying land use changes under warming climates influence aggregation through altered thermal amplitudes and

moisture regimes, which in turn affect porosity, bulk density, and infiltration potential (Li et al. 2023). Collectively, these climate-induced disruptions in soil structure, aggregation, and susceptibility to erosion threaten soil health, water retention, and ecosystem resilience.

Chemical properties: Ph, salinity, cation exchange capacity (CEC), and nutrient leaching

Under climate stressors such as shifting precipitation patterns, rising temperatures, and sea level rise, soil chemical properties are significantly disrupted. Soil Ph is highly sensitive to climate-driven changes in temperature, precipitation, and biogeochemical cycling. Increased precipitation and extreme rainfall events accelerate the leaching of base cations (Ca^{2+} , Mg^{2+} , K^{+} , Na^{+}), which normally buffer acidity, leading to progressive soil acidification (Yaseen 2024). At the same time, enhanced mineral weathering and the oxidation of soil organic matter under warming release hydrogen ions (H^{+}) and mobilize aluminum (Al^{3+}), further lowering Ph and impairing nutrient availability (Brinkman, 1990). In drought-prone regions, reduced leaching and the accumulation of soluble salts can, conversely, raise soil Ph (alkalinization), particularly in calcareous soils where carbonates become concentrated in the profile (Bui, 2017). Moreover, rising atmospheric CO_2 and associated shifts in soil respiration influence carbonic acid equilibria, which can modify Ph dynamics seasonally. Overall, climate stress exerts a bidirectional influence: acidification dominates in humid and high-rainfall systems, while alkalinization often occurs in arid and semi-arid landscapes both with profound consequences for nutrient cycling, microbial activity, and long-term soil fertility.

In coastal and semi-arid zones, sea-level rise and saltwater intrusion have increased soil salinity by between 1 % and 33 % over recent decades, while elevated evapotranspiration in arid regions inhibits salt leaching, promoting accumulation in the root zone (Rahman et al. 2018). Climate-induced warming accelerates the decomposition of soil organic matter (SOM), which critically underpins soil Cation Exchange Capacity (CEC) a determinant of the soil's ability to retain key nutrient cations. As SOM declines, especially in coarse-textured or low-clay soils, CEC diminishes, reducing nutrient retention and amplifying leaching losses when intense precipitation occurs (Mandal and Sathyaseelan, 2012). Together, these shifts diminish nutrient retention, elevate the risk of nutrient leaching, and impair soil fertility and ecosystem function under ongoing and future climate stress.

Biological properties: microbial diversity, processes, and symbioses

Climate-induced stressors such as warming, drought, and altered precipitation patterns have pronounced effects on soil microbial diversity, functional processes, and symbiotic relationships. Meta-analyses reveal that on average, global warming reduces soil bacterial and fungal diversity by approximately 16% and 20%, respectively, with projected declines reaching 56% (bacteria) and 81% (fungi) under high-emission scenarios by mid-century trends that threaten soil organic carbon (SOC) sequestration and ecosystem resilience (Sun et al. 2025). Long-term experimental observations in grasslands indicate that warming restructures microbial successional trajectories, making fungal communities increasingly divergent over time and emphasizing deterministic environmental filtering over stochastic assembly (Guo et al. 2018). Drought compounds these effects: prolonged moisture deficits and elevated temperatures significantly alter the composition of bacterial and fungal communities, reduce their richness, and disrupt established symbioses, including mycorrhizal colonization patterns (Seaton et al. 2012). At the functional level, changes

in temperature and precipitation influence the complexity of microbial networks. In temperate steppes, warming has been shown to increase fungal network complexity and stability, particularly during cooler seasons, indicating a shift toward more interconnected, fungi-driven processing networks (Yu et al. 2024). Moreover, symbiotic relationships are altered: drought promotes arbuscular mycorrhizal fungi (AMF) colonization and structural adaptations like increased hyphal networks and vesicle formation, enhancing plant drought tolerance and nutrient uptake via osmolyte production and water relations adjustments (Silva et al. 2025). Collectively, climate stress reduces microbial diversity, reshapes community assembly, alters biogeochemical functioning, and reshapes symbiotic partnerships, with profound implications for nutrient cycling, plant resilience, and ecosystem stability.

CONSEQUENCES FOR AGRICULTURAL PRODUCTIVITY

Climate-induced soil degradation exerts cascading effects on agricultural systems, ultimately eroding crop yields, resource efficiency, and resilience.

Declines in Crop Yields and Soil Multifunctionality

Climate driven soil degradation, reflected in declines in soil organic carbon, increased erosion, loss of structural integrity, and reduced microbial function, significantly undermines both crop yields and soil multifunctionality. Intense warming and drought drive accelerated SOC decomposition and erosion, reducing moisture retention, nutrient availability, and key ecosystem services that support plant growth (e.g., carbon and nutrient cycling) (Cheng et al. 2017). Empirical modeling shows that warming reduces global yields of maize by 3.4%, wheat by 2.4%, rice by 0.3%, and soybean by 5%, while improving SOC can dramatically mitigate these losses bringing yield reductions down to near-neutral levels in many cases (Deng et al. 2023). Furthermore, precipitation reduction in semi-arid grasslands disrupts microbial biodiversity and network complexity, resulting in diminished soil multifunctionality such as nutrient provisioning, microbial growth efficiency, and organic matter decomposition (Wang et al. 2023). Conservation agriculture, which enhances soil health through practices like reduced tillage and increased SOC and microbial biomass, has been shown to sustain or even boost crop yields (e.g., 9.3% wheat yield increase) under long-term warming, highlighting how degraded soils may lose resilience in the absence of such practices (Teng et al. 2024). Together, these findings illustrate a clear mechanistic pathway: climate-induced soil degradation erodes the suite of soil functions that underpin crop productivity and ecosystem resilience, unless countered by proactive soil management strategies.

Nutrient Inefficiencies and Increased Fertilizer Demand

Climate driven soil degradation, including the loss of organic matter, erosion, altered moisture regimes, and disruption of nutrient cycling, exacerbates nutrient inefficiencies in agroecosystems and consequently increases fertilizer demand. Declining soil organic matter (SOM) and fertility force farmers to rely more heavily on synthetic fertilizers, yet as SOM diminishes, soils' physical and biological ability to retain nutrients also deteriorates, causing a substantial portion of applied nutrients to be lost to leaching or volatilization (Mosier et al. 2021). For example, degraded dryland agroecosystems often exhibit both nutrient depletion and reduced fertilizer-use efficiency, prompting escalating fertilizer applications that further increase greenhouse gas emissions (Iqbal et al. 2023). Furthermore, rising temperatures above critical thresholds (e.g., 28 °C) have been empirically linked to sharp increases in fertilizer use particularly

nitrogen in irrigated regions, as farmers attempt to offset heat- and moisture-induced yield declines, even as nutrient uptake efficiency falls (Quan et al. 2024). Together, these dynamics reveal a vicious cycle: climate stress degrades soil, impairs nutrient retention, and forces greater fertilizer inputs, often with diminishing returns and increased environmental and economic costs.

Water Stress and Drought Vulnerabilities

Climate-driven soil degradation such as erosion, loss of organic matter, structural decline, and vegetation removal, significantly heightens water stress and drought vulnerability in agroecosystems. The degradation of soil structure and aggregation due to intensified erosion and compaction diminishes infiltration rates and reduces soil water-holding capacity, leading to faster runoff and reduced water availability during dry periods (Radulov and Berbecea, 2023). Degraded soils lacking organic matter retain less moisture and are more prone to moisture deficits under warming and erratic precipitation, which amplifies drought impacts on plant growth and ecosystem resilience (IUCN, 2024). Land-use changes such as deforestation and the conversion of forests and rangelands to bare or cultivated land further impair the land's capability to buffer drought by disrupting vegetation cover and hydrological buffering (Liu et al. 2025). Empirical evidence from drought studies also shows that soil drying reduces microbial function and alters soil carbon and nitrogen processes, degrading the soil habitat and making ecosystems less resistant to prolonged water deficits (De Silva, 2025). Together, these processes create a feedback loop whereby degraded soils lose both physical and biological resilience, leaving landscapes more susceptible to water stress and prolonged drought under changing climate conditions.

Enhanced Greenhouse Gas Emissions and Feedbacks

Climate-induced soil degradation through warming, drying, erosion, and land-use change leads to an increase in greenhouse gas emissions from soils, thus reinforcing a positive feedback loop that accelerates climate warming. Experimental warming studies demonstrate that a ~1.5 °C rise in temperature significantly elevates soil CO₂ emissions (~13%), nitrous oxide (N₂O) emissions (~35%), and methane (CH₄) emissions (~23–38%) in various ecosystems, collectively adding 1.8 gigatonnes CO₂-equivalent per year and undermining the mitigation potential of terrestrial carbon sinks (Liu et al. 2020). Decomposition of previously stable soil organic carbon including deep SOM and permafrost carbon is accelerated by microbial activity under warming conditions, potentially releasing hundreds of petagrams of carbon over time and substantially reducing overall SOC storage (Cheng et al. 2017). Soil erosion and topsoil loss also enhance CO₂ emissions: an experimental study found that removal of the top 20 cm of soil increased seasonal CO₂ efflux from cropland, whereas adding soil reduced emissions, indicating that degradation itself can amplify GHG flux (Liang, 2018). In peat-rich ecosystems, draining and degradation of peatlands commonly undertaken for agriculture, transforms these systems from net carbon sinks into potent sources of CO₂ (and additionally CH₄ upon rewetting), making them a major driver of GHG emissions (Leifeld and Menichetti, 2018). Together, these processes illustrate that soil degradation triggers heightened emissions of CO₂, N₂O, and CH₄, creating self-reinforcing feedbacks jeopardizing both soil carbon stocks and broader climate stability.

Table 1. Climate Change Impacts on Agricultural Productivity

Process	Impact Mechanism	Productivity Consequence
Yield reduction	Stress from heat, drought, and fragmentation of multifunctionality	Lower output and food security risks
Nutrient losses	Leaching, runoff, low CEC	Reduced fertilizer efficiency, increased inputs
Water stress	Poor infiltration, structure loss, reduced water retention	Greater drought sensitivity, yield instability
Greenhouse feedbacks	SOC loss and N ₂ O emissions	Climate feedback loop and inefficiency

MITIGATION AND ADAPTATION STRATEGIES

Soil resilience to climate change depends on integrated, site-specific combinations of practices that protect soil structure, rebuild organic matter, improve nutrient and water use efficiency, and enhance biological function. Below we synthesize the evidence for key strategies and note important caveats.

Conservation agriculture (reduced/no-till, residue retention, cover crops)

Conservation agriculture (CA), anchored by the principles of reduced or no-tillage, residue retention, and diversified cropping (including cover crops), serves as a pivotal approach for both climate change mitigation and adaptation in agroecosystems. Reduced soil disturbance preserves structure and surface organic matter, enhancing water infiltration, reducing erosion, and promoting soil carbon accumulation (Zomer, 2017). Residue retention and cover cropping further bolster these benefits by maintaining soil moisture, regulating temperature extremes, and incrementally increasing soil organic carbon (SOC), soil aggregation, and nutrient cycling (Page, 2020). Meta-analyses reveal that CA often enhances yields modestly with cumulative gains in maize of ~4 % while improving drought resilience and yield stability under variable rainfall (Corbeels et. Al. 2020). Significantly, CA practices substantially reduce nitrous oxide (N₂O) emissions by about 7 % with no-till alone, and up to 30 % when combined with residue retention and rotation and increase crop yield by over 9 %, offering synergistic mitigation and productivity gains (Zhu et al. 2025). In drought settings, implementing cover crops and residue retention has shown striking results for example, soybean yields up to 29 % higher, along with improved water-use and photosynthetic performance (Whippo, 2024). Altogether, conservation agriculture offers a multifaceted strategy: it mitigates greenhouse gas emissions, enhances soil health and resilience, and stabilizes crop productivity under climate stress though site-specific outcomes may vary.

Organic matter management: composts, manures, green manures, and biochar

Organic matter management, including the application of composts, manures, green manures, and biochar, is increasingly recognized as an effective strategy for mitigating and adapting to climate change impacts on agricultural productivity. The incorporation of composts and animal manures improves soil fertility by supplying essential macro- and micronutrients,

enhancing cation exchange capacity (CEC), and stimulating beneficial microbial activity, which together bolster plant growth and resilience under climate stress (Goldan et al. 2023). Green manures, particularly legumes, contribute biological nitrogen fixation and enhance soil organic carbon (SOC) stocks, thereby improving soil aggregation, water-holding capacity, and nutrient cycling, which are critical under conditions of drought and variable rainfall (Mandal et al., 2004). Biochar, due to its stability and high carbon content, provides long-term carbon sequestration potential while also enhancing soil structure, nutrient retention, and water-use efficiency, and has been shown to reduce nitrous oxide (N₂O) and methane (CH₄) emissions from soils (Lehmann et al., 2011). Empirical studies demonstrate that co-application of biochar with organic manures or compost further improves soil physicochemical properties, crop productivity, and microbial community dynamics, highlighting the synergistic potential of integrated organic matter management strategies (Wang et al. 2019). Collectively, these practices not only enhance soil health and crop yields but also provide critical climate mitigation benefits by sequestering carbon and reducing greenhouse gas emissions, positioning them as vital tools for sustainable agriculture in a warming world.

Integrated nutrient management (INM) and precision fertilization

Integrated Nutrient Management (INM), which combines organic sources (e.g., manures, composts, crop residues) with judicious use of inorganic fertilizers, enhances soil fertility, synchronizes nutrient release with crop demand, and improves nitrogen use efficiency thereby reducing greenhouse gas emissions and enhancing resilience under climate variability. Long-term field studies in rice–wheat systems demonstrate that INM significantly boosts soil organic carbon (SOC), aggregate stability, and soil health compared to sole inorganic treatments, while supporting sustained crop productivity (Paramesh et al. 2023). Empirical trials in dryland maize production reveal that INM using crop residue plus fertilizer substantially increases SOC (by up to ~52%) and enhances water retention, thereby bolstering drought resilience and productivity (Wang et al. 2023). Precision fertilization through spatial diagnostics, remote sensing, and targeted nutrient placement further refines INM by aligning application timing and dosage with site-specific crop needs, minimizing nutrient losses (e.g., nitrate leaching, N₂O emissions), and enhancing fertilizer use efficiency (Bayu, 2020). Overall, the integrated application of INM and precision fertilisation offers a robust pathway for climate-smart agriculture, achieving dual goals of improved productivity and reduced environmental impact under changing climatic conditions.

Water management: mulching, micro-irrigation, and landscape retention

Effective water management strategies encompassing mulching, micro-irrigation, and landscape-level retention, play a critical role in enhancing agricultural resilience amid climate change. Mulching, whether organic (e.g., straw, gravel) or synthetic (e.g., plastic film), significantly reduces soil evaporation, moderates soil temperature, enhances moisture retention, suppresses weeds, and improves soil structure and fertility, thereby reducing irrigation demand and promoting water-use efficiency under arid and semi-arid conditions (El-Beltagi et al. 2022). Micro-irrigation systems, such as drip or trickle irrigation, deliver water precisely to the root zone, minimizing losses via evaporation or runoff; they enhance water-use efficiency, support deeper root development, and can be integrated with fertigation for optimized nutrient delivery (Bwire et al. 2024). The synergy between mulching and micro-irrigation yields even greater benefits: combining mulching with drip systems can reduce water consumption by as much as 40–50%,

decrease irrigation needs by 30%, and substantially boost crop yield and water productivity in vegetable production. At the landscape or catchment scale, soil mulching and micro-irrigation can lower the blue water footprint, delivering water savings of millions of cubic meters per year in some basins (Nouri et al. 2019). Furthermore, strategic landscape water retention such as enhancing soil organic carbon can markedly buffer yield losses under drought, as demonstrated in modeling studies showing that a 1% increase in soil organic carbon reduced potato yield loss from 16.4% to 7% during a severe drought (Heinz et al. 2025). Collectively, these practices form an integrated adaptation and mitigation framework, reducing vulnerability to shifting precipitation and water stress, stabilizing crop outputs, and enhancing efficiency and sustainability of agricultural systems in a warming climate.

Agroforestry, diversification, and perennial integration

Agroforestry, diversification, and perennial integration constitute complementary mitigation–adaptation strategies that increase the resilience and sustainability of agricultural landscapes by strengthening ecological function, buffering climatic shocks, and enhancing long-term productivity. Agroforestry by integrating trees and shrubs with crops and/or livestock modulates microclimate, reduces erosion and surface runoff, improves water and nutrient retention, and stores carbon in woody biomass and soil, thereby delivering both adaptation and mitigation co-benefits at field and landscape scales (Ghanbari et al. 2025). Crop and system diversification (spatial, temporal and genetic diversification, intercropping and mixed farming) reduces yield and income volatility, spreads climate and pest/disease risk across species and time, and improves soil health and biological pest regulation, making farm livelihoods less sensitive to extreme weather and market shocks (Mihrete and Mihretu, 2025). Integrating perennial species whether as tree crops, forages, silvopasture, or newly domesticated perennial grains reduces the need for annual tillage, increases below-ground carbon allocation through deeper, longer-lived root systems, curbs nutrient leaching and erosion, and can improve drought resilience through more extensive water capture and use (Chapman et al. 2022). When combined in diversified, perennial-rich agroecosystems (for example agroforestry mosaics, perennial–annual polycultures, and mixed silvopasture), these approaches produce synergistic outcomes higher and more stable ecosystem services (carbon sequestration, water regulation, soil conservation), improved on-farm biodiversity, and reduced vulnerability of production systems to climate variability while also opening policy and market pathways for scaling adoption.

Biological and engineered soil amendments (microbial inoculants, engineered bio-products)

Biological and engineered soil amendments including microbial inoculants and cutting-edge bioengineered products offer promising pathways to bolster agricultural resilience amid climate change. Microbial inoculants, or plant growth–promoting microorganisms (PGPMs), improve soil health by enhancing nutrient cycling, increasing plant resilience to drought and salinity, and reducing reliance on synthetic fertilizers and pesticides a source of considerable greenhouse gas emissions (Díaz-Rodríguez et al. 2025). These inoculants help restore soil microbial communities degraded by intensive agriculture, enriching ecosystem functions crucial for climate mitigation and sustainable productivity (Campos-Avelar et al 2023). Furthermore, targeted applications of PGPMs in wheat under drought stress have demonstrated significant improvements in plant drought tolerance, biomass, and soil enzymatic activity highlighting their

practical effectiveness under abiotic stress (Li et al. 2023). In parallel, engineered bio-products such as biochar produced via pyrolysis of organic biomass provide multifunctional benefits: sequestering carbon over centuries, enhancing soil water-holding capacity and nutrient retention, increasing microbial activity, and reducing emissions of nitrous oxide and methane (Shyam et al. 2025). Emerging biochar–microbe synergistic systems have shown spectacular results; for example, in calcareous soils, combining biochar with auxin-producing microbial inoculants (and L-tryptophan) improved canola yield by over 200%, while amplifying nutrient uptake and soil microbial activity (Mustafa et al. 2025). These methodologies underscore a powerful suite of mitigation and adaptation strategies: they enhance soil function, improve plant stress tolerance, and help sequester carbon all critical in transitioning toward climate-smart agriculture.

Policy, incentives, and carbon programs

Policy frameworks, targeted incentives, and carbon programs form a crucial triad for catalyzing climate-resilient agricultural transformations. Effective policy instruments ranging from subsidies, taxes, rural finance, land tenure reforms, extension services, to certification schemes, can significantly enhance the adoption of climate-smart agricultural (CSA) practices among smallholder and large-scale farmers, by reducing financial risk and aligning actions with public goods objectives (Van Asseldonk et al. 2023). Carbon programs, including credits for soil carbon sequestration or regenerative practices, offer a direct financial reward mechanism for climate-positive farming. Yet program design matters greatly: recent reporting highlights that in the U.S., while programs like the USDA’s EQIP and related climate-smart initiatives channel billions in incentives, over half the funding may not effectively reduce greenhouse gas emissions; implementation gaps likewise limit program efficacy (The Guardian, 2024). Similarly, corporate-led carbon credit initiatives, such as those by Indigo Ag, have supported farmers transitioning to regenerative agriculture by paying premiums for verified carbon credits, yet critics warn that delays in payments and inequitable cost-sharing can undermine farmer engagement (Reuters, 2024). Internationally, the European Union’s Common Agricultural Policy (CAP) and eco-schemes offer adaptation and mitigation support via agri-environmental commitments and climate-related rural development funds, although recent critiques argue that policy alignment with climate goals remains inconsistent due to imprecise metrics and diluted incentives (European Commission, 2025). Collectively, these insights underscore that a blend of well-calibrated policies, robust incentive structures, and transparently governed carbon programs is essential for driving agricultural systems toward sustainability, resilience, and equitable climate mitigation.

FUTURE DIRECTIONS AND RESEARCH GAPS

Safeguarding soil health under climate change requires closing several scientific and implementation gaps. Below I synthesize the most important open questions highlighted in recent literature, then propose concrete research priorities to guide the next decade of work. Key thematic gaps are

6. Measurement, monitoring, reporting and verification (MRV) for soil carbon and other soil health indicators;
7. Mechanistic understanding of carbon stabilization and losses across depths and land-uses;
8. The soil microbiome as an actionable lever for resilience;
9. Scalable, location-specific practice packages and socio-economic pathways to adoption; and

10. Modelling and remote sensing tools for up-to-date, trustworthy decision support.

RECOMMENDATIONS

Safeguarding soil health in the era of climate change requires integrated approaches that bridge scientific research, land management, and socio-economic policy. Healthy soils underpin climate mitigation and adaptation by sequestering carbon, regulating water, and supporting biodiversity, yet they remain vulnerable to degradation from unsustainable practices, land-use change, and governance gaps. Embedding soil health explicitly into climate policies at national and international levels is therefore essential to meet long-term environmental and food security goals, as exemplified by initiatives such as the European Union's Green Deal.

At the same time, economic incentives play a pivotal role in aligning farmer and landowner decision-making with environmental objectives. Payment for ecosystem services, subsidies for agroecological practices, and programs that reward carbon sequestration can make sustainable land stewardship financially viable. Secure land tenure and robust governance frameworks further underpin these efforts, empowering communities to prioritize long-term soil health investments over short-term exploitation.

Moving forward, several priorities emerge for policymakers and practitioners. Developing standardized soil health indicators encompassing physical, chemical, and biological dimensions, will enable consistent monitoring and adaptive management across regions. Greater investment in research and farmer education is equally vital, fostering innovation and knowledge transfer that accelerate the adoption of resilient practices. Moreover, the promotion of sustainable agricultural systems, including crop rotation, cover cropping, reduced tillage, and organic farming, offers proven pathways to strengthen soil functions and buffer climate extremes. Finally, broad-based public awareness and inclusive stakeholder engagement are critical to ensure that soil health remains a shared societal priority.

In sum, advancing soil health requires more than agronomic interventions; it demands coherent policies, supportive institutions, and active engagement across scales. By aligning science, practice, and governance, soil can be secured as both a natural capital asset and a cornerstone of climate resilience in the decades ahead.

CONCLUSION

Soil health is a cornerstone of sustainable development and climate resilience. Effective policies that integrate soil conservation into broader environmental and economic frameworks are essential for safeguarding this vital resource. By implementing the recommendations outlined above, governments can foster an environment where soil health is prioritized, leading to enhanced agricultural productivity, environmental sustainability, and climate change mitigation.

ABSTRACT

The integration of organic fertilizers into horticultural systems has gained increasing importance as a sustainable strategy to enhance soil fertility and crop productivity under challenging soil conditions. This study aimed to evaluate the effects of various organic fertilizers including manures from small ruminants, cattle, poultry, and vermicompost on the chemical properties of a sandy-calcareous soil and the growth performance of melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.). The study focused on how recommended fertilizer doses influence soil chemical quality and plant growth. The results indicated that organic fertilization altered soil electrical conductivity (EC) and available phosphorus (P) levels. Poultry and cattle manures led to notable improvements in soil nutrient content. Additionally, plant growth parameters such as stem diameter and fruit weight were positively affected by organic fertilizers, particularly poultry manure. Crop-specific responses were observed: melon plots exhibited higher soil EC and available P, while watermelon plants showed superior performance in stem diameter, fruit flesh thickness, and soluble solid content. In contrast, melon plants recorded higher chlorophyll levels. Overall, poultry manure emerged as the most effective input for enhancing plant growth, while vermicompost and cattle manure also contributed depending on the crop type. These results suggest that organic fertilizers, especially poultry manure, are valuable tools for improving soil fertility and crop productivity in calcareous soils.

Keywords: Calcareous soils, Fruit quality, Mediterranean climate, Organic amendments

INTRODUCTION

Sustainable agricultural systems are an emerging model that promotes the integrated use of organic materials as alternatives to chemical inputs are being developed to ensure more environmentally friendly and efficient food production. In this context, organic fertilizers that enhance soil fertility have come to the forefront. The core component of organic fertilizers, organic matter, serves as a primary source of energy and nutrients for soil-dwelling microorganisms. However, in Turkey and many other agricultural countries, inadequately matured animal manures characterized by high C/N ratios and the presence of root rot pathogens or weed seeds have long been used in crop production. These manures often fail to provide the expected agronomic benefits for both soil and plants (Karaman 2012).

In recent years, there has been a growing demand particularly in intensively cultivated horticultural and greenhouse production areas for thermally treated or fermented organic fertilizers. This trend reflects efforts to promote sustainable agriculture and to optimize the

combined use of organic and chemical fertilizers. Nevertheless, these processed fertilizers are significantly more expensive than traditionally matured manures, due to additional processing, packaging, registration, and storage costs. Furthermore, their claimed benefits for practical use often rely more on manufacturer assertions than on robust scientific evidence. Therefore, it is essential to evaluate their effects on soil fertility and plant growth in order to better understand their potential contribution to sustainable agricultural systems and to promote their effective and economical use.

Melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.), among the most widely produced and consumed vegetables globally and in Turkey, are annual crops adapted to warm and temperate climates. While both crops are cultivated in open fields and greenhouses, only about 3% of melon and 2% of watermelon production is conducted under protected cultivation (Anonymous 2001; Taşkaya and Keskin 2004). These crops are valued not only for their edible parts but also for their seeds and rinds, which are utilized across the food, pharmaceutical, and cosmetic industries, making them strategic export commodities. Deep, well-drained, sandy-loam or loamy-sand soils with high water-holding capacity are ideal for watermelon cultivation, while poorly drained soils with shallow groundwater levels (below 1 meter) are unsuitable (Tuna and Özer 2005). Like many other cultivated plants, melons and watermelons respond positively to organic fertilization. Accordingly, the application of solid and/or organic fertilizers in the cultivation of these crops is considered important for improving both yield and quality, as well as enhancing soil health (Bayram et al. 2020).

In this study, the effects of processed organic fertilizers including sheep, cattle, and poultry manures, as well as vermicompost on the chemical properties of calcareous sandy soils and on plant growth in melon and watermelon cultivation were investigated. Additionally, the study aimed to assess how the optimum application rates recommended by organic fertilizer manufacturers for plant growth influence soil fertility. By comparing the effects of these commonly used organic fertilizers on both soil chemical parameters and plant growth indicators, this study identified the strengths and weaknesses of each fertilizer type. The findings offer valuable insights into the practical use of organic fertilizers in sustainable farming systems.

MATERIAL AND METHODS

Site Description

This study was conducted as a field trial at the Finike campus of Akdeniz University (36°18'31"N, 30°08'48"E; altitude: 40 m). According to meteorological data collected during the trial period, the site had an average daily temperature of 19.3 °C, an average daily sunshine duration of 9.10 hours, an average daily open surface evaporation of 125.58 mm, an average daily rainfall of 1.4 mm, an average daily wind speed of 1.6 m/sec, and an average relative humidity of 66.03%.

Soil samples collected to represent the trial area were analyzed prior to the experiment. The soil was classified as sandy loam in texture. It had a neutral pH and was classified as non-saline. The soil also contained a high level of lime and was rated as sufficient in terms of humus content. Total nitrogen (N) and available phosphorus (P) levels were determined to be adequate, while the cation exchange capacity (CEC) was classified as low.

Organic Fertilizers and Fertilization Practices

In this trial, various heat-treated organic fertilizers (processed at 65–70 °C) were applied, including small ruminant manure (goat and sheep manure; T1), cattle manure (T5), poultry manure (T4), and vermicompost (T2) (Table 1). Additionally, control (T3) plots were established, which received only chemical fertilizers (detailed below) without any organic fertilizer input. The application rates of the organic fertilizers were determined based on the manufacturers' recommendations and supported by findings from previous studies (Maltaş 2023; Maltaş et al. 2024). This approach aims to develop practical organic fertilization strategies suitable for field conditions, specifically for melon and watermelon cultivation, while improving soil chemical properties and supporting plant growth.

Table 1. Some properties of organic fertilizers used in the experiment

Parameter	Organic fertilizer			
	Vermicompost	Chicken manure	Cow manure	Goat-sheep manure
Organic matter, %	45	62	35	70
EC (dS/m)	6.0	2.6	11.2	7.5
Organic C, %	26.1	35.96	20.3	40.6
Humic/fulvic acid, %	41.5	36	15	28
Total N, %	3.0	2.2	1	1.5
Total P, %	1.5	1.76	1.5	1.5
Total K, %	1.0	1.62	-	2
Humidity max., %	20	20	20	20
pH	6-8	6.2	7-9	8-10
C/N	9/1	16/1	20/1	27/1
C/P	17/1	20/1	13/1	27/1

The application rates were as follows: 4 Mg ha⁻¹ for vermicompost, 8 Mg ha⁻¹ for cattle manure, 6 Mg ha⁻¹ for goat manure, and 4 Mg ha⁻¹ for poultry manure. In addition to these inputs, chemical fertilizers certified for use in organic farming were applied through a drip irrigation system to support plant nutrition throughout the experimental period. These chemical inputs were selected based on the initial soil analysis and estimates of nutrient removal by the crops (Zengin 2023).

Previous studies have demonstrated that the use of organic mulching materials (such as straw, sawdust, and compost) can improve microclimatic conditions and enhance the effectiveness of organic fertilizers (Gao et al. 2019; Teasdale and Mohler 2000). Mulching has been shown to promote soil biological activity, thereby improving nutrient uptake efficiency by plants and contributing to sustainable farming practices (Li et al. 2019). Therefore, in this study, a mulch was applied to the experimental plots to maximize the effectiveness of organic fertilizers.

Implementation of the Experiment

In this study, melon and watermelon cultivation was carried out using four types of heat-treated organic fertilizers. The experimental setup was established according to a randomized block design with three replications. The organic fertilizers were applied uniformly to the plots based on their respective application rates (in dry weight).

Melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.) seedlings were procured from a commercial nursery. Melon seedlings (Anka F1) were transplanted at a spacing of 2.0 m between rows and 0.3 m within rows, while watermelon seedlings (Peykan F1) were

planted at 2.0 m between rows and 0.6 m within rows. Both crops were cultivated over a vegetation period of approximately 90–100 days.

Throughout the growing period, all essential cultural practices such as weed control, hoeing, and plant protection treatments were carried out. In addition, irrigation and fertigation were performed using a drip irrigation system. The daily irrigation requirements of the plants were calculated based on climatic parameters (including rainfall, temperature, and relative humidity), soil texture and moisture, and plant needs (e.g., signs of wilting). These water requirements were integrated with the optimized fertilization strategy to ensure proper crop management.

Sampling and Analysis

Soil samples were air-dried and sieved through a 2 mm mesh prior to analysis. To characterize the initial soil conditions, samples were collected from the 0–30 cm soil depth using an auger before the experiment began. These samples were analyzed for texture, pH, electrical conductivity (EC), lime content, organic matter, total nitrogen (N), available phosphorus (P), and cation exchange capacity (CEC). Additionally, to evaluate the effects of organic fertilizer applications on soil chemical properties, samples collected at harvest were analyzed again for organic matter, total nitrogen, available phosphorus, and CEC.

The methods used for analyzing the above-mentioned soil parameters were as follows: soil texture was determined using the hydrometer method (Bouyoucos 1955); pH and EC were measured in a 1:2.5 soil-to-water suspension (Jackson 1967; Anonymous 1982); lime content was determined using the calcimeter method (Çağlar 1949); organic matter was measured using the modified Walkley-Black method (Black 1965); total nitrogen was determined using the Kjeldahl method (Kacar 1995); available phosphorus was analyzed according to the Olsen method (Olsen and Sommers 1982); and CEC was determined using the ammonium acetate method (Kacar 1995).

At the end of the experiment, pomological and physiological traits were assessed in plant and fruit samples (Figure 1 and Figure 2). For each treatment replication, measurements and evaluations were performed on three randomly selected plants per plot. The results were expressed as the average of these three plants.

Figure 1. Views of selected physiological and pomological traits in watermelon plants (A: Soluble solids content, B: Chlorophyll content, C: Fruit flesh thickness, D: Stem base diameter, E: Fruit juice pH, F: Fruit weight)

Figure 2. Views of selected physiological and pomological traits in watermelon plants (A, C: Harvested fruits; B: Fruit juice pH)

The evaluated pomological characteristics included: stem base diameter (cm; measured with a caliper), fruit fresh weight (g; measured with a precision balance), and yield (kg da^{-1} ; calculated). The physiological parameters included: soluble solids content (SSC), fruit juice pH, total chlorophyll content (measured with a chlorophyll meter), and rind thickness (mm; measured with a caliper).

Statistical Analyses

The numerical data obtained in this study were statistically analyzed using the SPSS 23.0 software package. The significance levels of soil chemical properties and plant pomological and physiological parameters were determined through analysis of variance (ANOVA) at the 5% significance level. Parameters showing statistically significant differences were further evaluated using Duncan's multiple range test for mean separation. In addition, Pearson correlation analysis was performed to determine the relationships among the measured parameters (SPSS 2008).

RESULTS AND DISCUSSION

Soil Chemical Properties

At the end of the growing season, the effects of different organic fertilizer treatments on soil cation exchange capacity (CEC), organic matter (OM) content, total nitrogen (N%), and available phosphorus (P, mg/kg) were evaluated for watermelon cultivation (Table 2). According to the statistical analysis, changes in CEC, total N, OM (%), and available P values in watermelon plots were found to be statistically non-significant.

Table 2. Effects of applications on CEC, OM, total N and available P contents in watermelon soil

Treatments	CEC (meq/100)	% OM	% N	P (mg/kg)
T1	26.54	2.26	0.16	22.17
T2	29.33	2	0.15	19.47
T3	31.04	2.1	0.16	13.36

T5	30.58	1.92	0.18	38.54
ANOVA (%5)	NS ¹	NS	NS	NS

¹ NS; not significant.

In contrast, in melon cultivation plots, although changes in CEC, total N, and OM (%) were also statistically non-significant, the variation in available phosphorus content was statistically significant at the $P < 0.05$ level (Table 3). Among the treatments, T4 (48.60 mg/kg) resulted in the highest increase in available phosphorus content compared to the other applications.

Table 3. Effects of applications on CEC, OM, total N and available P contents in melon soil

¹ Differences between values not indicated by the same letter are significant at the 5% level. ² **, significant at the 1% level. ³ NS; not significant.

Previous studies have indicated that increasing doses of poultry manure significantly contribute to the enhancement of soil nitrogen content (Okur et al. 2008), while farmyard manure has been found to have a more pronounced effect on available phosphorus levels in soils (Agbenin and Goladi 1997). In the present study, the available phosphorus level in soils under melon cultivation (T4: 48.60 mg/kg) was approximately 20% higher than that in watermelon soils.

Göksu and Kuzucu (2017), in their study investigating the effects of different vermicompost doses on yield and quality parameters in watermelon, reported that vermicompost and chemical fertilizer applications increased the soil ion exchange capacity. However, in the current study, organic fertilizer treatments did not result in statistically significant changes in CEC for either melon or watermelon soils.

Similarly, Kılıç and Sönmez (2019), in their study on the effects of increasing doses of various organic materials (vermicompost, poultry manure, farmyard manure, leonardite) on soil fertility parameters in lettuce cultivation, found that the effects on soil organic matter content were statistically significant. In contrast, the findings of the current study showed that different organic matter applications had no statistically significant effect on soil organic matter levels in either melon or watermelon cultivation.

Plant Growth Properties

At the end of the cultivation period, among the yield and quality parameters obtained from the watermelon plant, leaf chlorophyll content (SPAD), fruit flesh thickness, fruit juice pH, and soluble solid content were found to be statistically non-significant (Table 4). However, collar

diameter was found to be statistically significant at the $P < 0.01$ level, with higher values observed in T1 and T4 (23.41 mm and 23.23 mm, respectively) compared to other treatments. Fruit weight was also found to be statistically significant at the $P < 0.05$ level, with higher fruit weights recorded in T2, T4, and T5 (7.38 kg, 8.13 kg, and 7.52 kg, respectively).

Table 4. Effects of treatments on SPAD, root collar diameter (RCD), fruit weight (FW), fruit flesh thickness (FFT), fruit juice pH (FJpH) and soluble solid content (SSC) in watermelon

Treatments	SPAD	RCA (mm)	FW (kg)	FFT (cm)	FJpH	SSC

Regarding the melon plant, leaf chlorophyll content (SPAD), fruit flesh thickness, fruit juice pH, and soluble solid content were also found to be statistically non-significant (Table 5). However, root collar diameter was found to be statistically significant at the $P < 0.05$ level, with higher values observed in T1, T3, and T4 (14.67 mm, 14.83 mm, and 14.85 mm, respectively). Fruit weight was found to be statistically significant at the $P < 0.01$ level, with the highest fruit weight observed in T1 (2.02 kg).

Table 5. Effects of treatments on SPAD, root collar diameter (RCD), fruit weight (FW), fruit flesh thickness (FFT), fruit juice pH (FJpH) and soluble solid content (SSC) in melon

Üçok et al. (2019), in their study investigating the effects of different organic fertilizer applications on yield, quality, and plant nutrient contents in lettuce (*Lactuca sativa* L. var. *crispa*), reported no significant differences in chlorophyll content among the treatments. Similarly, in our study, although the differences between applications were not statistically significant for both watermelon and melon plants, the chlorophyll value in melon was found to be approximately 20% higher than in watermelon.

Özen (2018) investigated the effects of different doses of mushroom compost, leonardite, and vermicompost on lettuce yield and quality, and reported that increasing doses of organic material applications resulted in increased collar diameter. In a study conducted on watermelon (*Citrullus lanatus* (Thunb.) Matsum & Nakai), it was reported that different doses of vermicompost (0, 300, and 600 kg/da) did not have statistically significant effects on fruit flesh thickness, fruit juice pH, and soluble solid content (Göksu and Kuzucu 2017). Similarly, in our study, although the differences between treatments were not statistically significant in both watermelon and melon, the collar diameter, fruit flesh thickness, and soluble solid content in watermelon were found to be 40%, 40%, and 100% higher, respectively, compared to melon. In addition, the fruit weight of watermelon was found to be six times higher than that of melon. One of the main reasons for this large difference is the physiologically larger fruit size of watermelon compared to melon.

Correlations Between Soil Properties and Plant Growth

Based on the numerical data obtained from the trial, relationships between soil chemical properties and plant growth parameters were examined. Accordingly, in melon soils, a negative correlation was observed between fruit flesh thickness and organic matter content ($r = -0.539^*$), while a positive correlation was found between root collar diameter and organic matter content ($r = 0.728^{**}$). These correlations suggest that soil organic matter may play a dual role in influencing plant morphological traits. While the positive correlation between root collar diameter and organic matter content implies a supportive role of soil organic matter in promoting vegetative growth and stem development, the negative correlation between fruit flesh thickness and organic matter content might indicate a potential trade-off between vegetative and reproductive growth processes under certain soil conditions. This could be due to nutrient partitioning or changes in water-holding capacity and aeration associated with increased organic matter. However, these relationships are likely to be influenced by plant species, growth stage, and environmental factors.

CONCLUSION

This study aimed to evaluate the effects of various organic fertilizers including manures from small ruminants, cattle, poultry, and vermicompost on the chemical properties of a sandy-calcareous soil and the growth performance of melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.). The study focused on how recommended fertilizer doses influence soil chemical quality and plant growth. Poultry and cattle manures stood out in improving soil chemical properties in watermelon cultivation areas, whereas vermicompost and poultry manure significantly enhanced plant growth parameters. For melon cultivation, cattle manure was most effective for soil chemical improvements, while small ruminant, poultry, and cattle manures showed prominent positive effects on plant development. Overall, poultry manure emerged as the most effective input for enhancing plant growth, while vermicompost and cattle manure also contributed depending on the crop type. These results suggest that organic fertilizers, especially poultry manure, are valuable tools for improving soil fertility and crop productivity in calcareous soils. Nonetheless, expanding these findings through comprehensive studies involving different crops, soil types, cultivation locations, and production systems (e.g., greenhouse or organic farming) will be essential to deepen understanding and broaden the applicability of these organic fertilization strategies. These results underscore the critical role of optimized organic fertilization in promoting sustainable agricultural productivity, supporting both soil health and crop performance in Mediterranean agroecosystems.

ABSTRACT

Cancer is a disease caused by uncontrolled cell proliferation and abnormal cells that gain the ability to spread to surrounding tissues. According to the 2025 Cancer Statistics, prostate, lung and colorectal cancers are the most common cancers in men, while breast, lung and colorectal cancers are the most common in women, with prostate and breast cancers alone having the highest rates.

In recent years, the increase in the incidence of cancer and its tendency to be seen at young ages has attracted attention, while healthy nutrition and natural bioactive compounds, especially medicinal mushrooms (such as *Inonotus obliquus*, *Schizophyllum commune*, *Trametes versicolor*, *Grifola frondosa*, *Ganoderma lucidum*, *Lentinula edodes*, *Laetiporus sulphureus*, *Boletus edulis*) have significant potential in the field of cancer prevention and supportive therapy.

In this study, it was aimed to investigate the cytotoxic activity of different extracts of *Inonotus tamaricis* (Pat.) Maire from Southwest Anatolia, Türkiye, against lung and colon cancer cell lines (A549 and HT-29) and healthy fibroblast cell line (CCd18Co). This mushroom is naturally distributed in south west anatolia, non-toxic, consumed as tea and has commercial potential. Extractions of the fungus (hexane, ethyl acetate, methanol and water) were carried out according to increasing polarity respectively, then the cytotoxic activities of the extracts were investigated using MTT method. As a result, ethyl acetate extract of *I. tamaricis* showed highly selective cytotoxic activity against HT-29 colon cancer cells (IC₅₀: 25.02 µg/mL). In A549 lung cancer cells, IC₅₀ was determined as 150.81 µg/mL. Hexane and water extracts were moderately effective in HT-29 (IC₅₀ ~100 µg/mL), while methanol extract showed weak activity. All extracts showed low toxicity in healthy fibroblast cells (IC₅₀ >100 µg/mL). *I. tamaricis* shows a promise as a source of bioactive compounds and detailed phytochemical investigations are needed. Future studies on this species may reveal new bioactive metabolites with pharmaceutical potential, especially in colon cancer.

Keywords: *Inonotus tamaricis*, mushroom, cytotoxic activities, MTT, lung cancer, colon cancer

INTRODUCTION

In recent years, there has been a significant increase in the incidence of cancer worldwide and the average age of patients is getting younger. This trend poses serious risks to the general health status and treatment processes of cancer patients (Górska-Jakubowska et al., 2025). In 2025, the most commonly diagnosed cancers in men are prostate cancer (30%), lung cancer (11%) and colon & rectal cancer (8%), accounting for around 48% of all new cases, with prostate cancer alone accounting for 30% of cases. In women, breast cancer (32%), lung cancer (12%) and colon &

rectum cancer (8%) accounted for 51% of all new diagnoses, with breast cancer alone accounting for 32% of cases (Siegel et al., 2025).

Fortunately mushrooms contain polysaccharides (especially β -glucans), triterpenoids and phenolic compounds and wood mushrooms show protective effects against cancer by mechanisms such as strengthening the immune system, reducing oxidative stress and regulating the cell cycle (Deveci et al., 2019; Zhao et al., 2021; Meng et al., 2022; Korkmaz et al., 2024;). The anticancer, antioxidant, antitumor, antiviral, antibacterial, antifungal, anti-inflammatory, immunomodulatory activities and cholesterol-lowering effects of lectins, polysaccharides, polysaccharide-peptides, polysaccharide-protein complexes, lanostene-type triterpenoids, phenolic and flavanoid-structured compounds obtained from edible mushroom species have been revealed (Duru and Çayan, 2015; Maity et al., 2021; Lowenthal et al., 2023; Şavkancı et al., 2024). Recent studies support the anticancer potential of species such as *Ganoderma lucidum* (Reishi), *Trametes versicolor* (Turkey tail) and *Inonotus obliquus* (Chaga) (Tel-Çayan et al., 2015; Camilleri et al., 2024; Górska-Jakubowska et al., 2025; Ikram et al., 2025).

Türkiye, has a very important geographical position in terms of species richness of macromycetes. *I. tamaricis* belongs to the Hymenochaetaceae family (Sesli et al., 2020). In this present study, *I. tamaricis*, which is naturally distributed in our country, consumed as tea and has commercial potential, was extracted with increasing polarity (hexane, ethyl acetate, methanol and water) and cytotoxic activities of the extracts on lung (A549) and colon cancer (HT-29) cell lines as well as normal colon cell line (CCd18Co) were investigated using MTT ((3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) method.

MATERIAL AND METHOD

1. Mushroom Material

I. tamaricis was collected from *Tamarix parviflora* DC species in this natural habitat in Datça, Türkiye. The collected samples were taxonomically identified using the identification keys provided by Piątek (2001), Ghobad-Nejhad and Kotiranta (2008), Sharma et al. (2013), and the updated List of Fungi of Turkey (Sesli et al., 2020). A voucher specimen was deposited in the Natural Products Laboratory of Muğla Sıtkı Koçman University under the code ME2305. Macroscopic images of *I. tamaricis* is shown in Figure 1.

Figure 1. Macroscopic views of *I. tamaricis*

2. Mushroom Extract

A total of 1000 grams of dried *I. tamaricis* material was subjected to solvent extraction at room temperature using a sequential method with increasing solvent polarity: hexane, ethyl acetate, methanol, and water. Each extraction was performed three times (24 h $\times$ 3). After filtration, solvents were evaporated under reduced pressure using a rotary evaporator. The masses and yields of each extract are listed in Table 1.

Table 1. Quantities and yields of *I. tamaricis* extracts.

Mushroom	Extract	Code	Quantities (g)	% Yields
<i>I. tamaricis</i>	Hexane	ICH	1.95	0.20
	Ethyl acetate	ICE	20.33	2.03
	Methanol	ICM	12.95	1.30
	Water	ICS	9.94	0.99

3. Cytotoxic Activity

The cytotoxic effects of *I. tamaricis* extracts (hexane, ethyl acetate, methanol and water) were evaluated against two human cancer cell lines A549 (lung cancer cell line) and HT-29 (colon cancer cell line) as well as a non-tumorigenic normal human colon fibroblast cell line (CCd18-Co). Cytotoxicity was assessed using the MTT assay (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide), according to the method described by Plumb (2003) and Korkmaz et al (2024). The IC₅₀ values ($\pm$ standard deviation) for each extract were calculated for the 72-hour treatment period to assess the cytotoxic potential against cancer cell lines and normal cell lines.

4. Statistical Analysis

For cytotoxic activity, statistical analysis was performed using GraphPad Prism version 8, including one-way ANOVA followed by Tukey's multiple comparison tests. p value < 0.05 was considered statistically significant. The IC₅₀ values were determined from regression curves generated from the percentages of inhibition or absorbance at different concentrations, as previously described.

RESULTS AND DISCUSSION

The cytotoxic effects of *I. tamaricis* extracts (hexane, ethyl acetate, methanol and water) on A549 and HT-29 cancer cell lines and healthy human cell line CCD18Co were determined after 72 hours treatment based on IC₅₀ values. The cytotoxic activity results of the extracts are given in Table 2.

Table 2. Antioxidant Activity Results of *I. cuticularis* Extracts (p<0.05).

Extracts/ Reference	Cancer Cell Lines		Human Healthy Cell Line
	A549	HT-29	CCD18-Co
	IC ₅₀ (μ g/mL)		
Hexane	>200	100.02 $\pm$ 0.03*	>100
Ethyl acetate	150.81 $\pm$ 0.03	25.02 $\pm$ 0.02*	180.85 $\pm$ 0.05
Methanol	>200	147.25 $\pm$ 0.04	>200
Water	172.53 $\pm$ 0.02	100.03 $\pm$ 0.07*	>100
Reference			

Cisplatin	4.28±0.05	4.05± 0.04	NT

*Activity results expressed as mean ± standard deviation (SD) of 3 parallel tests (p<0.05)

As shown in Table 2, at the end of the 72-hour test period, *I. tamaricis* ethyl acetate extract showed the highest cytotoxic activity in HT-29 (IC₅₀: 25.02± 0.02 µg/mL) and A549 cell lines (IC₅₀: 150.81± 0.03 µg/mL) compared to other extracts (hexane, methanol and water). Because IC₅₀ value (180.85µg/ml) of ethyl acetate for normal cell line CCD18-Co is higher than those of A549 and HT-29, it can be concluded that ethyl acetate extracts of *I. tamaricis* is selective for cancer cell lines.

The hexane and water extracts of *I. tamaricis* showed moderate cytotoxic effect on HT-29 cancer cell line (IC₅₀: 100.02± 0.03 and IC₅₀: 100.03± 0.07µg/mL, respectively) compared to methanol extract (IC₅₀: 147.25± 0.04 µg/mL). In contrast, the toxicity of all *I. tamaricis* extracts on healthy human fibroblast cell line was IC₅₀>100.

The main active components of polysaccharide (anticancer, anti-inflammatory, antiviral, antioxidant, immunomodulatory, hypoglycemic, hypolipidemic, hepatoprotective), polyphenol (antioxidant), triterpenoid (anticancer, anti-inflammatory, antiviral) and melanin (antioxidant, anti-inflammatory, antiviral) isolated from the tree fungus *Inonotus obliquus* (Hymenochaetaceae) have been reported to be the source of increasing pharmacological research over the last two decades (Lu et al. , 2021; Camilleri et al., 2024; Ikram et al., 2025). In the study by Lee et al. (2021), substance found in Chaga (*I. obliquus*) called ergosterol peroxide works as an antiproliferative agent and prevents colony formation in colon cancer cell lines. By inhibiting the -catenin pathway in colorectal cancer, it raises the possibility that it can be used to treat the disease (Camilleri et al., 2024).

We believe that in the future, the extraction, purification and identification techniques of bioactive compounds from edible and medicinal fungi will be improved; the mechanism of anticancer effects (especially targeted studies in colon cancer) of these species will be more comprehensively understood and will find wider use in pharmaceutical applications.

CONCLUSIONS

In conclusion, ethyl acetate extract of *I. tamaricis* exhibited higher cytotoxic activity against cancer cell lines compared to the other extracts examined in this study. Therefore, ethyl acetate extract of this macrofungi requires extensive research on the characterization and purification of their bioactive metabolites, potentially opening new windows in mycochemistry, natural discovery and medicine.

ACKNOWLEDGEMENT

This study is supported by TUBITAK 2218 domestic postdoctoral research fellowship program number 123C399 hosted by Muğla Sıtkı Koçman University. The authors would like to thank “TUBITAK 2218 domestic postdoctoral research fellowship program (BİDEB 2218)” for providing a postdoctoral fellowship to Cansu Korkmaz.

CURRENT STATUS AND POTENTIAL APPLICATION OF MICROALGAE PRODUCTION

Seyit Uguz, Arda Sozcu, Ercan Simsek, Erkan Yaslioglu

ABSTRACT

Microalgae production has garnered significant attention across various industries due to its diverse applications and potential benefits. This study explores the current status and potential applications of microalgae production, focusing on its role in biodiesel production, cosmetics, thalassotherapy, bioremediation, and feed materials. The high lipid content of certain microalgae species makes them a promising source for sustainable biofuels, while their utilization in cosmetics and thalassotherapy underscores the value of microalgae-derived compounds in high-value products. Microalgae are also being explored for bioremediation purposes, particularly in treating textile wastewater, showcasing their versatility in environmental applications. Genetic engineering strategies are being developed to enhance biofuel production by increasing lipid accumulation in microalgae strains.

Keywords: Microalgae, feed, food, biofuel, treatment, waste

INTRODUCTION

Microalgae production has gained significant attention due to its diverse applications and potential benefits across various industries, including renewable energy, biopharmaceuticals, and nutraceuticals. The potential of microalgae production extends to biofuels, feed, food products, and other valuable compounds. Researchers have highlighted the rich energy content, rapid growth rate, cost-effective cultivation methods, and environmental benefits of microalgae, positioning them as a promising feedstock for biofuel generation. The current status of microalgae production is characterized by ongoing research and technological advancements aimed at maximizing the efficiency and scalability of microalgae cultivation. One prominent application of microalgae lies in biodiesel production, where the high lipid content of certain microalgae species presents a promising source for sustainable biofuels (Wu et al., 2012). Beyond biofuels, microalgae are being explored for bioremediation purposes, particularly in treating textile wastewater, showcasing the versatility of microalgae in environmental applications (Andrade & Andrade, 2018). The potential of microalgae extends to genetic engineering for enhanced biofuel production, with metabolic engineering strategies being developed to increase lipid accumulation in microalgae strains (Banerjee et al., 2016). Moreover, the biotechnological applications of microalgae have expanded to include the production of cosmetics, health products, fertilizers, feeds, and food, emphasizing the versatility of microalgae biomass in various industries (Ugya & Meguellati, 2022). Additionally, the utilization of microalgae in cosmetics and thalassotherapy has gained traction, highlighting the value of microalgae-derived compounds in high-value products (Mourelle et al., 2017).

The biotechnological potential of native microalgae from diverse ecosystems, such as the Peruvian Amazon, underscores the growing relevance of microalgae biotechnology in harnessing

unique strains for specific applications (Cobos et al., 2020). Furthermore, the incorporation of microalgae into innovative food products and the extraction of valuable compounds like phytosterols for functional food and pharmaceutical applications highlight the growing interest in utilizing microalgae for health and nutrition purposes (Caporgno & Mathys, 2018; Luo et al., 2015). The development of low-cost and high-volume open microalgae biofuel production technologies signifies progress towards commercial-scale microalgae biofuel production, addressing the need for sustainable and renewable energy sources (Moheimani et al., 2013). Additionally, the genetic manipulation of microalgae for bioproducts and enhancing microalgae traits demonstrate the continuous advancements in biotechnology for optimizing microalgae-based applications (Vázquez-Villegas et al., 2018; Shin et al., 2016).

In conclusion, the current status and potential applications of microalgae production encompass a wide range of industries, from biofuels and cosmetics to bioremediation and feed products. The ongoing research and technological innovations in microalgae cultivation and genetic engineering are paving the way for a sustainable and versatile bio-based economy with microalgae at its forefront.

Curent status of Microalgae Production

Potential Applications

Food and feed material

Microalgae production is recognized for its potential as a sustainable and versatile source of food and feed materials, offering a wide array of nutritional and functional benefits. Microalgae have historically been consumed by humans for their nutritional value and medicinal properties (Sathasivam et al., 2019).

Studies have demonstrated the feasibility of large-scale cultivation of microalgae for feed purposes, particularly in livestock and poultry production (Saadaoui et al., 2021). In the realm of food production, microalgae present a sustainable alternative as feed material for monogastric animals, providing a viable option to supplement or replace traditional feedstuffs like corn and soybean (Chaves et al., 2021). The nutritional composition of microalgae, which includes proteins, polyunsaturated fatty acids, antioxidants, and phytosterols, positions them as promising sources for food and feed applications (Sui & Vlaeminck, 2020). Additionally, the bioactive lipids found in microalgae have applications not only in aquaculture feed but also in the food and pharmaceutical industries, showcasing the versatility of microalgae-derived compounds (Luo et al., 2015).

Microalgae play a crucial role in aquaculture by serving as essential sources of polyunsaturated fatty acids for aquatic species (Soto-Sánchez et al., 2023). Their high nutritional value makes them suitable food sources for larval bivalves, shrimps, and fish, emphasizing their significance in aquaculture feed formulations (Ma, 2023). Furthermore, the industrial utilization of microalgae biomass includes the production of feeds, underscoring their importance in the food chain (Ugya & Meguellati, 2022). The nutritional composition and functional properties of microalgae proteins have been well-established, positioning them as a simple and effective protein source for food and feed applications (Hashim et al., 2023). Commercially, microalgae are already integrated into various food products, demonstrating their potential as versatile ingredients with nutritional benefits (Igual et al., 2021). The expanding industrial applications of microalgae encompass food, nutraceuticals, pharmaceuticals, animal feed, cosmetics, and biofertilizers, showcasing the diverse opportunities presented by these microorganisms (Udayan et al., 2021).

Microalgae production holds vast promise as food and feed material, providing sustainable and nutrient-rich alternatives for various industries. The nutritional value, bioactive compounds, and functional properties of microalgae make them valuable resources for addressing food scarcity, ensuring adequate nutrition, and promoting sustainable living practices.

Pharmaceutical and cosmetic industries

The pharmaceutical sector is increasingly exploring the therapeutic potential of microalgae-derived compounds, such as antioxidants, anti-inflammatory agents, antimicrobials, and anti-cancer agents, highlighting their pivotal role in biomedical applications (Khavari et al. 2021). These bioactive metabolites from microalgae hold significant promise for developing novel pharmaceutical products due to their diverse pharmacological activities (Kaur et al., 2023). In the cosmetic industry, microalgae have gained attention for their cosmetic and cosmeceutical applications, with compounds like astaxanthin being utilized as pigments in cosmetics and as active ingredients in skincare products (Villaró et al., 2021). The bioactive compounds present in microalgae, including pigments, vitamins, and minerals, offer a natural and sustainable source for formulating cosmetic products, catering to the increasing consumer demand for natural and eco-friendly alternatives (Dussably et al., 2022). Moreover, marine microalgae and cyanobacteria have been identified for their potential use in cosmetics and thalassotherapy, underscoring their significance in the cosmetic industry (Mourelle et al., 2017). The pharmaceutical and cosmetic industries are increasingly turning to microalgae as a valuable resource for developing high-value products. Microalgae's ability to produce a wide range of bioactive compounds, such as carotenoids, phytosterols, and fatty acids, positions them as versatile sources for pharmaceutical and cosmetic applications (Balasubramaniam et al., 2021). The bioactive metabolites synthesized by microalgae have demonstrated antioxidant, anti-inflammatory, and anti-microbial properties, making them attractive candidates for pharmaceutical formulations and cosmetic products (Morais et al., 2015). Furthermore, the sustainable production of microalgae biomass offers a cost-effective and environmentally friendly approach to sourcing bioactive compounds for pharmaceuticals and cosmetics (Jeevanandam et al., 2020). The potential of microalgae in producing value-added lipids, proteins, and other bioactive molecules presents opportunities for developing innovative pharmaceutical and cosmetic formulations (Conde et al., 2021). The bioprospecting of microalgae for biopharmaceutical applications underscores the growing interest in harnessing the therapeutic potentials of microalgae in the pharmaceutical industry (Saeed et al., 2021). In conclusion, microalgae production holds immense promise for the pharmaceutical and cosmetic industries, offering a sustainable and bioactive-rich source for developing a wide range of products. The diverse bioactive compounds synthesized by microalgae present opportunities for formulating novel pharmaceutical drugs, nutraceuticals, and cosmetic products, catering to the evolving needs of these industries.

Biodiesel production

Microalgae production has attracted significant interest as a sustainable and efficient feedstock for biodiesel production, offering a promising solution to the global energy demand and environmental concerns. The potential applications of microalgae in biodiesel production have been extensively studied, highlighting their viability as a renewable energy source (Ajala et al. 2022). Microalgae possess characteristics that make them ideal for sustainable biodiesel production, including high lipid content and the ability to be genetically optimized for enhanced lipid accumulation (Mohamed et al., 2022).

The utilization of microalgae for biodiesel production involves various advanced technologies and influencing parameters that contribute to maximizing the efficiency of lipid extraction and conversion processes (Cao et al., 2013). The unique properties of microalgae, such as their ability to effectively remove nutrients and heavy metals from wastewater, further enhance their appeal as a biodiesel feedstock (Cobos et al., 2020). Additionally, the direct conversion of lipids within microalgae cells into biodiesel through in situ transesterification has emerged as an effective and simplified approach in biodiesel production (Hidalgo et al., 2015).

The potential of microalgae for biodiesel production extends to their high lipid content, which allows for the generation of saturated and monounsaturated fatty acids ideal for biodiesel

synthesis (Mohammed et al., 2022). The sustainable production of biodiesel from microalgae offers advantages over traditional plant crops, as microalgae can accumulate significant quantities of triglycerides and free fatty acids, making them a valuable resource for biofuel production (Andrade & Andrade, 2018). Furthermore, the joint production of biodiesel and bioethanol from microalgae biomass presents a cost-effective and efficient approach to biofuel production (Sendzikiene & Makareviciene, 2022). The biodiesel potential of microalgae is further underscored by their ability to grow in the presence of sunlight and carbon dioxide, making them excellent sources of biofuels after processing (Ma et al., 2014). The differential fatty acid profiles of microalgae grown with organic materials highlight the versatility of microalgae in biodiesel production and wastewater treatment applications. The integration of oleaginous microalgae cultivation with wastewater treatment is considered a low-cost and sustainable approach for producing algae-based biodiesel.

Biomethane and biogas production

Microalgae production has emerged as a promising avenue for biomethane and biogas production, offering sustainable solutions for renewable energy generation and waste management. The potential applications of microalgae in biomethane and biogas production have been extensively explored, showcasing their versatility as a renewable energy feedstock (Poggio et al. 2023). Microalgae possess unique characteristics that make them ideal for biomethane and biogas production, including their ability to capture CO₂ and convert it into valuable methane gas (Prandini et al., 2016). The integration of microalgae-based wastewater treatment with biogas purification accelerates nutrient removal while producing valuable biomass and biomethane, highlighting the dual benefits of microalgae in waste management and energy production (Ahmad et al., 2014). Furthermore, co-digestion of microalgae with organic waste streams, such as palm oil mill effluent, has been shown to enhance biogas and biomethane production rates, demonstrating the potential of microalgae in optimizing anaerobic digestion processes (Córdova et al., 2018).

The advantages of using microalgae as a substrate for biogas and biomethane production stem from their high productivity, ability to capture CO₂, and convert organic matter into biofuels efficiently (Jensen & Skovsgaard, 2017). The upgrading of raw biogas to biomethane involves removing excess CO₂ to produce a higher quality fuel suitable for various applications, such as transportation and heat generation (Machado, 2023). The scalability of anaerobic digestion of microalgae biomass within water resource recovery facilities further emphasizes the potential of microalgae in large-scale biomethane production (Milbrandt et al., 2016). Photosynthetic biogas upgrading has enabled the production of biomethane while concurrently treating digestate in constructed wetlands to obtain biofertilizers, showcasing the integrated approach of utilizing microalgae for energy and environmental benefits (Díez-Montero et al., 2020). The techno-economic analysis of biogas production from microalgae through anaerobic digestion highlights the feasibility and sustainability of biomethane production from this renewable feedstock (Murano et al., 2021). Moreover, modeling studies on hydrogen sulfide removal under biomethane production underscore the importance of optimizing biogas purification processes for efficient biomethane generation (Chernysh et al., 2021).

Bioremediation of air and wastewater

Microalgae have been recognized as a versatile and sustainable solution for bioremediation of air and wastewater, offering a promising approach to environmental cleanup and resource recovery. Extensive research has demonstrated the ability of microalgae to efficiently remove pollutants and contaminants from various environmental matrices (Jalilian et al. 2020; Uguz et al., 2022). Microalgae are well-known for their capacity to thrive in wastewater environments and effectively remediate pollutants, making them valuable assets in the pursuit of cleaner ecosystems and sustainable resource management.

The utilization of microalgae for bioremediation of wastewater presents a win-win paradigm, where the bioremediation capacity of microalgae is harnessed to treat wastewaters, thereby promoting the development of the microalgae industry and offering alternatives to conventional wastewater treatment processes (Delrue et al., 2016). Microalgae-based bioremediation processes have been shown to be cost-effective, energy-efficient, and highly effective in reducing pollutant levels compared to traditional wastewater treatment methods (Singh et al., 2022). The ability of microalgae to assimilate organic nutrients from wastewater for growth while simultaneously reducing pollutant content underscores their dual role in bioremediation and biomass generation (Chew & Show, 2022). Studies have demonstrated that microalgae can effectively remove contaminants from wastewater, leading to a reduction in biological oxygen demand and nutrient levels, thereby contributing to cleaner water sources and sustainable environmental practices (Rawat et al., 2011). The bioremediation potential of microalgae extends to the treatment of various types of wastewaters, including industrial effluents and urban waste, highlighting their versatility in addressing pollution challenges (Mutanda et al., 2020). The integration of microalgae-based bioremediation processes with biofuel production further enhances the sustainability and efficiency of wastewater treatment, offering a holistic approach to environmental stewardship (Renuka et al., 2014). Moreover, the application of microalgae in bioremediation of air and wastewater is not only effective in pollutant reduction but also contributes to biomass production, which can be utilized for various purposes, including biofuel production and nutrient recycling (Miazek et al., 2015). The ability of microalgae to thrive in contaminated environments and remove pollutants, such as heavy metals and organic compounds, underscores their potential as eco-friendly bioremediation agents (Li et al., 2018). The integration of microalgae with other remediation technologies, such as sulfate-reducing bacteria, in continuous treatment systems further enhances the efficiency and effectiveness of bioremediation processes. In conclusion, microalgae offer a sustainable and effective solution for bioremediation of air and wastewater, providing a dual benefit of environmental cleanup and biomass generation. The diverse applications and promising results of microalgae-based bioremediation processes highlight the potential of microalgae in promoting environmental sustainability and resource recovery.

CONSLUSION

Microalgae production is at the forefront of a sustainable bio-based economy, with applications in various industries. High lipid content in some microalgae species makes them a promising source for sustainable biofuels, addressing energy demands and environmental concerns. Their bioactive metabolites are increasingly used in pharmaceuticals and cosmetics. Microalgae biomass production provides a cost-effective and eco-friendly source of bioactive compounds for these industries. On the other hand, microalgae offer nutrient-rich alternatives for livestock, poultry, aquaculture feed, and food products, addressing food scarcity and promoting sustainability. Additionally, microalgae serve as feedstock for biomethane and biogas, offering renewable energy solutions and waste management. Integrating microalgae-based wastewater treatment with biogas purification accelerates nutrient removal and biomass production, showcasing dual benefits. Their application in bioremediation of air and wastewater offers sustainable solutions for environmental cleanup, contributing to cleaner ecosystems. In summary, microalgae-based technologies hold significant potential for environmental sustainability, resource recovery, and developing a bio-based economy that addresses energy demand, pollution, and resource management challenges.

THE ROLE OF THE WOMEN ON ACHIEVING THE LDN

Pınar Topçu

Strategy and Budget Office, Ankara, Türkiye

Corresponding author e-mail: topcupinar08@gmail.com

ABSTRACT

Land degradation is one of the most significant problems affecting global habitats, leading to a decrease in productivity and food production. Considering these negative and destructive effects, urgent and decisive actions need to be taken on a global scale. Despite there being individual country efforts on this issue, it is also on the agenda of the sustainable development. In this regard, the concept of Land Degradation Neutrality (LDN) is seen as an important tool, aiming to prevent land degradation where possible and to restore degraded land in other cases. There are numerous links between the LDN and the Sustainable Development Goals (SDGs). One of the main ones is the role of women farmers in providing the LDN target. The women farmers are predominantly employed in low-paid and precarious jobs in the agriculture and are therefore disproportionately affected by the socio-economic challenges posed by the land degradation. In order to achieve the LDN objectives, a gender equality perspective needs to be integrated into the process and women's knowledge, labour and leadership must be brought to bear in the agriculture sector. Based on this information, the results of the survey in Türkiye conducted within the scope of the study in order to show the impact of women farmers on achieving the LDN goals are shared.

Keywords: Women, Survey, Sustainability, Degradation, Land Management

INTRODUCTION

Population growth continues with a rising momentum, and ongoing expectation is to reach approximately 9.8 billion by 2050, which significantly result in increases in food demand (UN, 2025). 2025 Global Report on Food Crises points out that 53 countries and regions experience acute food insecurity and need urgent food, nutrition, and livelihood assistance in 2024 (GRFC, 2025). In this case, Türkiye ranks 49th among 113 countries in terms of the 2022 Global Food Safety Index (GFSI, 2022). In addition to this indicator, Türkiye differs from the other countries in terms of some economic aspects, e.g. food price stability.

Besides this situation, degradation processes become a dominant pressure on arid and semi-arid fragile parts of Türkiye (Karagöz et al., 2017). Recently, it is reported that 12.7% of total land is categorized as “weak”, 53.2% is “moderate”, and 25.5% is located in the “high-risk” class in terms of desertification scale (CEM, 2017; Türkeş et al., 2019). Due to these compelling effects on limited natural resources, the Ankara Initiative has been prepared (UNCCD, 2019) to achieve Land Degradation Neutrality (the LDN) as a priority step to be taken by Türkiye. In addition to reaching the LDN targets, this document also aimed to implement the decisions taken at the 12th meeting of the Conference of the Parties to the Convention on Biological Diversity (COP 12) and the United Nations Sustainable Development Goals (SDGs).

The SDGs serve as an important tool in reaching the LDN. While some targets focus on solely the biophysical indicators, the others, concentrate on the socio-economic structure. Among them, only SDG 15 (Life on Land) has a direct relation with the LDN. The sub-goal 15.3 of the SDG 15 is particularly effective in determining the targets for extensively degraded countries

(FAO, 2019; UN, 2021). Otherwise, SDG 5 (Gender Equality) is also related to implemented activities of soil conservation and management (UN Women, 2019; Topcu, 2019) (Figure 1). In particular, research on the LDN can advocate for the women's land ownership and contribute to SDG 5 (Feng et al.,2022).

Figure 1. Empowering the women farmers for land restoration

As emphasized by Liniger et al. (2019), Sustainable Land Management (SLM) helps to halt the land degradation. Ensuring that the land users are supported by financial resources, an enabling legal framework and, in particular, information on the SLM practices is the most rational way to promote the adoption of the SLM and ultimately the achievement of the LDN.

Considering the pressure of the agricultural sector on natural resources, it is important to strengthen the effectiveness of the women farmers, who play an active role in the agricultural sector, in the field for the sustainable management of the agricultural lands. However, the male farmers mainly have been worked with in projects and activities aiming to improve the living standards of local people living in rural areas and to reduce the problems in the agricultural sector, and the women farmers have been mostly neglected in this process. Consequently, as a result of the acceptance of the women only as “agricultural labourers”, “land” has come to be seen only as a “working area” for the women farmers. This has caused natural assets, which should be used and managed with a sustainable approach, to become a commercial commodity.

Furthermore, it is known that the women farmers who are actively involved in agriculture are seen as agricultural labourers and do not have any role in the land ownership or decision-making processes in production. Indeed, the women farmers need to be more active in the field due to the pressure of the agricultural sector on natural resources in order to ensure sustainable management of the agricultural lands. In this context, trainings on awareness-raising activities should be organized to include the women farmers and projects for the women should be diversified. Regarding this issue in Türkiye, projects and programmes such as Contribution of Women's Cooperatives in Rural Areas to Social Change: The Case of Ankara Province, Women Farmers Agricultural Extension Project, Safe Agriculture and Healthy Nutrition Project with Women and Their Families are being carried out.

The purpose of this study is to reveal the role of the women in land acquisition and sale transactions, their place in agricultural education and extension services, their activity in agricultural production and their status in decision-making processes by utilising the survey findings applied to two districts with intensive land use due to agricultural activities.

MATERIAL AND METHOD

The study area is particularly selected in central Anatolia where rainfed agriculture under semi-arid climate prevails as irrigated agriculture concentrates at the valley bottoms of mountainous topography. The main reason of choosing Kırbaşı and Tacettin villages was that the areas have a high-to-moderate sensitivity to desertification, and agricultural production activities are actively carried out by local farmers. The study was conducted in these villages in Beypazarı district located 100 km from the Ankara province in the Central Anatolia Region of Türkiye.

The economy of these villages is mainly based on the plant production. The average landholding size is 8-10 ha per household and significant numbers of scattered plots are very common. The reason for the fragmentation of these lands is that they are divided by inheritance, which has devastating effects on the stability of the agricultural sector in central Anatolian villages. The women farmers of the villages, who work as unpaid agricultural labourers, take an active part in almost all agricultural activities, mainly in crop production, as well as fulfilling household responsibilities such as child and elderly care. A survey of the study was conducted these two villages. The questionnaire was divided into seven main sections (Figure 2).

In the scope of this study, the questions belonging to sections 1 (General Information), 2 (Household Structure) and 6 (Gender Roles) were utilized.

Figure 2. Basic parts of the questionnaire

Face-to-face interviews were held with the 206 farmers who voluntarily accepted to do the survey. Particular attention was paid to the participation of female farmers as much as possible in the survey application. The study was based on 5% error margin and 95% confidence

level. In the analysis of the data, it was evaluated as percentage and frequency by using frequency analysis.

RESULTS AND DISCUSSION

In the “General Information” section of the questionnaire, “gender” and “age” information of the farmers in the two villages were included (Table 1). When the respondents are analyzed in terms of gender, 56.3% of the farmers are “men” and 43.7% are “women”. The minimum age of the interviewed farmers is 31, the maximum age is 74 and the average age is 52.8.

The household structure in the villages is presented in Table 2. When the household data are examined, it is seen that the weight of the household is mostly in families of “5” to “6” people. This shows that “family farming” is dominant in these villages. The family farmers have a great impact on the sustainable use and management of natural resources as well as their other role in society (Shaban et al., 2021). In particular, it is effective in the protection of soil ecosystems and the transfer of knowledge and culture between generations (FAO and IFAD, 2019).

The LDN-gender relationship was determined in the 6th section of the questionnaire (Table 3.). To the first question “The role of women in land acquisition and sale transactions” asked to the farmers operating in two villages, 72.8% answered “none” and 27.2% answered “yes”. Although the continuity of women-land-productivity is the life assurance of Anatolian society, an analysis of statistics over time reveals that the women engaged in agricultural activities are unpaid “agricultural labourers” rather than “land owners” (Sabbağ, 2017). However, the fact remains that empowering the women farmers by strengthening and enforcing land use and land decision-making rights can ensure long-term productivity thereby achieving the purpose of the LDN targets (Collantes et al. 2018).

On the other hand, studies show that the women farmers’ participation in agricultural extension services helps to reduce poverty, increase food security, improve family health and nutrition status, and create new job opportunities. In Table 3., 52.4% of the respondents answered “yes” and 47.6% answered “none” to the question “Involvement of the women in agricultural training and extension services”.

As Sharma and Badodiya (2016) emphasised, the women farmers face some challenges in carrying out their agricultural activities, such as access to finance. A reflected pattern of similar situations was observed for the farmers in these two villages. All of the farmers who participated in the survey (n: 206) answered “none” to the question “Women’s access to agricultural financial resources”, even though there are various agricultural support payments of the T.R. Ministry of Agriculture and Forestry and also Instrument for Pre-Accession Assistance for Rural Development (IPARD) supports with a special scope for Beypazarı district. This shows that these financial resources are available but access is mostly by the male farmers.

The women farmers continue to account for a large share of the labour force devoted to the agriculture. It indicates that the women farmers constitute about 43% of the agricultural labour force globally and in developing countries (FAO, 2011). Continuing in this section (Table 3.), 68.4% of the respondents answered “yes” and 31.6% answered “none” to the question “Women’s activism in agricultural production”.

All of the farmers responded as “none” to the question of “women having agricultural or non-agricultural business contacts”. This adverse situation once again highlights the fact that women are employed as family workers and that they need to be empowered in rural areas by increasing their opportunities to engage in individual work, particularly through cooperatives.

Lastly, regarding the role of women in decision-making processes within the scope of agricultural activities, 84% of the farmers stated “none” and 16% stated “yes”. Asking the farmers

who answered “yes” to this question, it was found that the women have a say in the decision-making process was stated by all of the farmers (n: 33) as “consulted/speaking in land sales”.

Table 1. General information of farmers (n=206)

Variable	Category	f	%
Gender	Women	90	43.7
	Men	116	56.3
	Total	206	100.0
Age	Mean age 52.8		

Table 2. Household structure (n=206)

Variable	Category	f	%
Family size (household size as person)	3	24	11.7
	4	33	16.0
	5	55	26.7
	6	49	23.8
	7	30	14.6
	8	12	5.8
	9	3	1.4
	Total	206	100.0

Table 3. Gender roles (n=206)

Variable	Category	f	%
The role of the women in land acquisition and sale transactions	Yes	56	27.2
	None	150	72.8
	Total	206	100.0
- If yes, why?	Consulted in buying and selling	42	75.0
	Has a say in buying and selling	14	25.0
	Total	56	100.0
Involvement of women in agricultural education and extension services	Yes	108	52.4
	None	98	47.6
	Total	206	100.0
- If yes, why?	Participates in trainings-courses	108	100.0
Access to agricultural financial resources	None	206	100.0
Active in agricultural production	Yes	141	68.4
	None	65	31.6
	Total	206	100.0
- If yes, why?	Works in the field	141	100.0
Having agricultural or non-agricultural business contacts	None	206	100.0
	Yes	33	16.0

The role of women in decision-making processes	None	173	84.0
	Total	206	100.0
- If yes, why?	Consulted/speaking in land sales	33	100.0

CONCLUSIONS

The findings show that the women farmers are still active in the agricultural lands, but they face some difficulties despite this vital role within the scope of the questions asked in the survey. Nevertheless, it is a fact that in order to ensure the SLM and thus the achievement of the LDN targets it is critically important that they have a say in the production phase, especially in the land ownership, and have easy access to financial resources. Therefore, any initiative on this subject will contribute to the achievement of this goal.

ACKNOWLEDGEMENTS

This study was conducted as a part of PhD thesis under the supervision of Prof. Dr. Günay Erpul. I would like to thank the staff of Ankara University and the farmers in the surveyed villages who contributed to the effective progress of the study.

ABSTRACT

The *Echium amoenum* Fisch & Mey., as a native plant of Iran, has unique properties in traditional Iranian medicine. *E. amoenum* is rich in numerous phytochemical compounds such as rosmarinic acid, anthocyanidins, and flavonoids that are utilized as a new source of materials in different industries such as drug, food, and cosmetic. These bioactive compounds are used for treatment of many infectious and fungal diseases such as herpes, oral infections, colds, pneumonia, congestion, coughs and stress. Microorganisms can interact with plants and play a significant role to produce plants with high nutritional value. Recently, the isolation of endophyte bacteria from some medicinal plants and their application as an elicitor, has attracted the attention of researchers. Hence, in this study, a novel strain of endophytic bacterium *Bacillus amyloliquefaciens* was isolated from the *E. amoenum* plants. After that, the elicitation effects of autoclaved bacteria were investigated on phenolic production of *E. amoenum* plant *in vitro*. Based on the results, total phenolic content and total flavonoid content were positively increased under the influence of different concentrations of bacterial extract. The results also showed that *Bacillus amyloliquefaciens* extract can be used as a new elicitor for the biosynthesis of phenolic compounds in future research.

Keywords: *Bacillus amyloliquefaciens*, Flavonoid, Interaction, Microorganism, Phenol

INTRODUCTION

Echium amoenum Fisch & Mey. (Gol-e-Gav-Zaban) belongs to the *Boraginaceae* family. This perennial plant, as a medicinal plant native to Iran, grows wild in the mountainous regions of northern Iran and the Caucasus. *E. amoenum* is a valuable medicinal plant that has been used for more than a thousand years in the treatment of many infectious and inflammatory diseases (Jamnani et al., 2023).

Phytochemical studies have indicated that *E. amoenum* has bioactive compounds, such as polyphenols, flavonoids, anthocyanins, shikonin derivatives, rosmarinic acid, and sterones. These phytopharmaceutical compounds possess a range of beneficial activities, including antibacterial, anti-mutagenic, anti-carcinogenic, cytotoxic, anti-inflammatory, antidepressant, and anti-proliferation properties. They are commonly used to treat various conditions such as herpes, oral infections, colds, pneumonia, sore throat, and cough. In addition, the extract of *E. amoenum* is used as a sedative in the treatment of stress and anxiety (Amjadi et al., 2023).

Medicinal plants are great reservoirs of microorganisms and valuable sources of specialized metabolites. The previous studies have revealed that endophytes can produce some secondary metabolites in their host plants (Ptak et al., 2022). However, data on the isolation of endophytes from the *Boraginaceae* family and their ability to biosynthesize polyphenols are limited. In a previous study, the endophytic bacteria belonging to the *Actinobacteria* phylum have been isolated

from *E. amoenum* plants. However, the *Bacillus* genus has not yet been isolated from *E. amoenum* (Oloumi et al., 2023).

Endophytic bacteria can be used as elicitors of metabolite biosynthesis in plants. Biotic elicitors can be either raw or autoclaved endophytic bacterial cells. According to previous studies, the autoclaved endophytic *Bacillus megaterium* was able to stimulate the production of quinone-methide triterpene in adventitious *Peritassa campestris* root cultures (Ptak et al., 2022). To our knowledge, no biotic elicitors have been studied in *in vitro* *E. amoenum* cultures. Therefore, in this study, the *Bacillus amyloliquefaciens* was identified and isolated from plants of *E. amoenum*. After that, the ability of *Bacillus amyloliquefaciens* to biosynthesize total phenolics and flavonoids was investigated.

MATERIAL AND METHOD

This study was conducted at the University of Mohaghegh Ardabili, Ardabil, Iran, in 2025. The *Echium amoenum* Fisch & Mey plants (Fig. 1A) were collected from the mountain regions of Ardabil. First, the roots were washed with water and surface disinfected with ethanol and hypochlorite. Finally, they were rinsed 3 times with sterile water, and the last rinse was cultured in LB agar plates to ensure the removal of non-endophytic bacteria. Then, the roots were cut into smaller pieces and placed in LB and PDA media and incubated at 37°C (Fig. 1B). After bacterial growth, several subcultures were performed, and bacterial colonies were isolated from each other.

Figure 1. A, collected *Echium amoenum* plants, B, root pieces cultured in PDA medium

Bacteria obtained from LB plates were used for DNA extraction. A single bacterial colony was inoculated into 10 mL of LB medium and placed in a 37 °C incubator on a shaker at 100 rpm. The cells were isolated by centrifugation at 6000 × g for 10 min. Pellet was used for genomic DNA extraction using the Ptak et al. method (Ptak et al., 2022). Taxonomic analysis of the isolated strain and search for the most similar species were done using the NCBI web server.

For elicitor preparation, briefly, one colony of isolated bacteria was incubated in 10 mL of LB liquid medium and placed at 37 °C on a shaker at 100 rpm for 24 h. After bacterial quantification and centrifugation, the supernatant was removed, and the cell sediment was resolved in sterile distilled water and applied for elicitation (Ptak et al., 2022).

Echium amoenum plants 1-month old were obtained from *in vitro* seed culture. These plants were transferred to a solid MS medium. Autoclaved *Bacillus amyloliquefaciens* group sp. strain

EA-1 was added to the medium at concentrations of 0% (as a control), 0.01%, 0.02%, and 0.04%. The pH of all media was adjusted to 5.8. This study was established in five replications. The plants were investigated for phytochemical analyses after 30 days.

Methanolic extract from leaf tissue was prepared using the Wang et al. method (Wang et al., 2015). The total phenolic content was quantified according to the Folin-Ciocalteu method (Singleton et al., 1965). The absorbance of the samples was read at 765 nm. Gallic acid was considered the standard (Fig. 2A). The total phenolic content was expressed as mg gallic acid equivalent (GAE) per 1 g FW (fresh weight). Total flavonoid content was measured using the aluminum chloride method. The sample's absorbance was read at 510 nm. Quercetin was used as a standard (Fig. 2B). Total flavonoid content was expressed as μg quercetin equivalent (QE) per 1 g FW (Wang et al., 2015).

This study followed a completely randomized design (CRD) with five replications. All quantitative data were subjected to one-way ANOVA using SAS 9.1 to indicate significant differences. Means were separated at a 5% level of probability by Dun- can's Multiple Range Test. All graphs were drawn with Excel.

Figure 2. A, gallic acid standard curve, B, quercetin standard curve.

RESULTS AND DISCUSSION

In this study, *Bacillus amyloliquefaciens* group sp. strain EA-1 was isolated from *Echium amoenum* plant roots (Fig. 3). Two 16S forward and reverse primers, including AGAGTTTGATCCTGGCTCAG and CGGTTACCTTGTTACGACTT, were used for PCR analysis, respectively. Genome sequencing of the isolated strain resulted in 1094 (forward) and 1114 bp (1114). Assemblies were finally deposited in the GenBank under the Bio Project number PV731489.1, and the strain was labeled as EA-1. Based on Blast in EzBioCloud and NCBI sites, it was found (when considering 16S rDNA sequence) that the most related species was *Bacillus amyloliquefaciens* group sp. To our knowledge, this is the first study to report the isolation of *Bacillus amyloliquefaciens* group sp. from *Echium amoenum* plant roots. Previously, Oloumi et al. isolated bacteria belonging to the *actinobacteria* from *Iris persica* and *E. amoenum* plants (Oloumi et al., 2023).

Figure 3. The isolated *Bacillus amyloliquefaciens* group sp. strain EA-1 from *Echium amoenum* plants on PDA medium

Endophytic bacteria live inside plant tissues without the plants exhibiting symptoms of disease. The result of this study indicated that endophytic *Bacillus amyloliquefaciens* group sp. strain EA-1 isolated from *Echium amoenum* plant roots increases the synthesis of phenolic compounds and flavonoid content. Based on this experiment, the autoclaved endophytic bacteria of *Bacillus amyloliquefaciens* group sp. strain EA-1 acted as an elicitor and increased the total phenolic content (88.5333 GAE mg/g FW) and total flavonoid content (2153 QE μ g/g FW) (Fig. 4A and 4B). Previous studies have revealed that the autoclaved endophytic *P. lautus* strain PLV increases the production of galanthamine and lycorine in *Leucojum aestivum* L. tissue cultures (Ptak et al., 2022). Liu et al. indicated that inoculation of in planta *Lycoris radiata* with live endophytic bacteria increased the plant dry weight, enhancing the total yield of alkaloids (Liu et al., 2020). Inacio et al. indicated that eliciting *Peritassa campestris* culture with autoclaved endophytic *Bacillus megaterium* increased the biosynthesis of 22 β -hydroxymaitenin (Inácio et al., 2017).

Figure 4. Effect of *Bacillus amyloliquefaciens* group sp. strain EA-1 elicitation on total phenolic content and total flavonoid content in *E. amoenum* in vitro plants. A, total phenolic content, and B, total flavonoid content. Different letters indicate significant differences determined using Duncan's multiple range test ($p < 0.05$). Error bars represent $\pm$ SE, $n=5$.

CONCLUSION

This research was conducted to isolate endophytic bacteria and investigate the effects of autoclaved endophytic bacteria as an elicitor on the synthesis of phenolic and flavonoid content in in vitro *Echium amoneum*. In this study, a new strain of *Bacillus amyloliquefaciens*, designated EA-1, was identified from the roots of *E. amoneum*. The obtained results revealed that this new elicitor increased the total phenol and total flavonoid content. Furthermore, it may elicit the biosynthesis of other secondary metabolites that can be investigated in future research.

ABSTRACT

Canned tuna is one of the most traded food products around the world due to its availability in processing and consumption. Similar to other seafood processing methods, many by-products are generated during the tuna canning process and utilization of these by-products in the alternative value-added products production is a promising approach for circular economy and the environment. In this research, tuna pate was produced with the usage of chunks and trimming of canned tuna products. For these aims, two tuna pate groups were produced from without or dill leaf addition. Then each pate group was separated into three sub-groups in terms of packaging material; flint glass (F), amber glass (A), and plastic container (P). Packaged tuna pate groups are stored in the refrigerator during six months. Sensory attributes such as colour, odour, taste, texture, and general acceptance were also determined. The results showed that the sensory quality of dill leaf enriched tuna pate groups had higher sensory scores than control tuna pate groups. The results has also revealed that the tuna pate groups in the glass jar, especially in amber glass groups compared to plastic container groups had been evaluated more appropriate by panelists.(P<0.05). These results revealed that the usage of dill leaf prolonged the shelf life of tuna pate within sensory quality of tuna pate. The structure and colour of packaging materials also impacted the quality of tuna pate sensory quality.

Keywords: Seafood, quality, sensory attributes, dill leaves, tuna, spreadable pate

INTRODUCTION

With increasing demand of healthy food products globally, alternative products have become popular in the food industry. In particularly, ready-to-eat food items are most commonly preferred by consumer due to can be easily consumed and do not required any process. Pate is one of the ready to eat food products containing meat, spice, additional oil and other food additives. Traditionally, pate prepared with goose liver which is known as "foie-grass", the increasing demand to this product and the price had to tended to producer usage to alternative sources. From pork livers and chicken livers to different animals offal have been used for pate production (Estévez et al., 2007; Polak et al., 2011). The market size of pate was more than a billion USD in 2018, and it is estimated to increase total size by 1.3 % up to 2025 (Grand View Research, 2019). Recently fatty fish species have used in pate production due to their functional characteristics resulted by fat content and health benefits. Higher bioavailability rate and containing 20% more protein than meat pate make fish pate a popular seafood product (Branciarri et al., 2019).

Especially, fatty fish species such as tuna and anchovy are used for pate production owing to their desirable taste and other sensory quality parameters.

Tuna species known as a large group of important fishes that belong to the Scombridae family, are classified into three genera, *Katsuwonus*, *Sarda*, and *Euthynnus* and one of the most consumed species globally (Abdullah and Rehbein, 2016). Especially canned tuna has been accepted as one of the traded food products due to its efficiency to processing, easy availability, and sensory attributes to consumer preference (Dantas et al., 2021). Same as other seafood processing methods, a wide range of by-products such as tuna trimming and tuna chunk generated during canning process (Malaweera and Wijesundara, 2014). Valorisation of these by-products in value-added novel food products offers economic and eco-friendly production with contributing to sustainable development goals and sustainable production. Since, pate products are highly susceptible to oxidation as a result of containing external high lipid rate and commonly fatty species preferred. Different processing techniques, using of natural antioxidants, packaging materials are robust approaches to avoiding chemical quality deterioration and improving sensory quality. Utilization of several plants directly using leaves or indirectly using extracts leads to delaying to oxidation in addition to improvement of the sensory attributes of food products. Thus, this research aimed to investigate dill leaf usage as taste enhancer and sensory quality improver of refrigerated tuna pate in different packaging materials during 6 months.

MATERIAL AND METHOD

Materials

Tuna (*Katsuwonus pelamis*) by-products (chunks and trimmings obtained after canned tuna processing) in pre-cooked form used as raw material for tuna pate production. The chunks and trimmings were obtained from seafood processing plant (Sasu Ltd., Adana, Turkey) the other ingredients (milk powder, spices, starch, and lemon juice) were obtained from local market located in Adana, Turkey in fresh form. Dill leaves (*Anethum graveolens*) were also obtained from the local market as fresh form and then washed, dried and grinded. All reagents used were of analytical grade and obtained from Sigma-Aldrich, Inc. (St. Louis, MO, USA) and Merck (Darmstadt, Germany).

Tuna pate preparation and storage

For the production of the tuna pate, tuna chunks and other ingredients were mixed in two different formulations. Frozen tuna trimmings and tuna chunks were thawed and chopped then mixed with mush potato, milk powder, salt, starch, and sunflower oil, spices and other ingredients in a dough mixer (AHE.PM.5, Alveo, Turkey) at 4°C until obtaining a homogeneous tuna trimmings dough (10 min). Mixed pate was divided into 2 groups: Control group (C) without any other ingredient, and for dill leaf enriched (DE) group, dried dill leaves and lemon juice were added to control groups while mixing slowly. Then, each pate group was divided into three sub-groups depending on packaging material (F: flint glass jar, A: amber glass jar and P: plastic container). Different tuna pate groups (C and DE) in different packaging materials classified as CF, CA, CP, DEF, DEA, DEP. The control and dill leaves enriched pate sample were manually full filled into the glass jars and plastic container as around 100 g. Then, the packaged tuna pate pasteurized at 80 °C for 45 min laboratory-type oven (Tefal model; 18L; Tefal, Barcelona, Spain) with slight modification the method described by Estévez, and Cava, (2004). Pate groups were stored under refrigerated conditions at 2±1 °C during 6 month. For each groups, sensory analysis were carried out on week 0, 7, 12, 16, 20, 22 and 24 of storage.

Sensory attributes of tuna pate during storage

The sensory evaluation of the tuna pate (CF, CA, CP, DEF, DEA, DEF) was conducted with 10 experienced panelists (5 women, 5 men). Panelists assessed flavor, odour, taste texture and general acceptance of pate groups. Sensory assessment performed with nine-point descriptive scale described by UNE 87-020-93 (UNE, 1993). According to scale, higher scores were evaluated as “good quality”, and lower scores evaluated as deterioration of quality.

RESULTS AND DISCUSSION

Sensory Attributes of tuna pate

The descriptive sensory attributes of tuna pates during storage period shown in Figure 1. Significant differences were detected related to sensory quality in terms of taste, odour, texture, general acceptance ($P < 0.05$). Dill leaf enrichment lead to improvement of sensory attributions of tuna pate regardless of packaging material especially for odour and taste parameters. Control groups reached the rejection limit at the 22th week of storage and the dill leaves enriched groups reached the same limit at the end of storage (24th week).

Dill leaves enrichment extended the shelf life of tuna pate stored in refrigerated storage by 2 weeks compared to the control tuna pate groups. Similar findings reported by Özoğul et al., (2017) who declared the usage of plant based material on the sensory quality of fish products.

Packaging material also impacts the sensory quality of tuna pate. While, tuna pate stored in plastic packaging material reached at the rejection limit at the 22th week, the tuna group stored in the glass jar achieved at the 24 th week of storage.

Figure.1. Sensory attributions of tuna pate during refrigerated storage

Groups: CF: Control tuna pate stored in flint glass jar, CA: Control tuna pate stored in amber glass jar, CP: Control tuna pate stored in plastic container, DEF: Dill leaf enriched tuna pate stored in flint glass jar, DEA: Dill leaf enriched tuna pate stored in amber glass jar, DEP: Dill leaf enriched tuna pate stored in plastic container

CONCLUSIONS

Due to sensory quality impacts on the product acceptability and the feasibility of processing of any food products, this quality is so important. Tuna pate enriched with dill leaf proved the sensory quality which could be related to lower oxidation capacity. In terms of packaging material, stored in glass jar especially in amber glass jar lead to higher sensorial acceptance. In terms of sensory attributes, texture, color, odor and general acceptance among tuna pate groups, dill leaf enrichment protect the sensory quality. This report recommended that dill leaf could be an useful taste and odor enhancer for other food items have high fat content such as pate products. Glass jar could be a more suitable packaging material for pate type products, especially during refrigerated storage. The findings of research revealed that usage of plant allows better quality of seafood in addition to improving of taste and the packaging material impact on the quality of food product, especially high lipid contained food.

ABSTRACT

While the importance of marine sources for not only food and feeding but also for biomaterial and sustainability of fisheries has become more essential for the public, decision-makers and researchers; the threat of invasive species on the marine sources has still been an important problem. According to the research, the main effects that threaten the coastal system are invasive species, tourism, destruction of the coasts and the lack of awareness of people. Alien species, which are one of these effects, face very different ecological factors in the geography where they have just moved. Some of these alien species spread rapidly, using the environment's available resources better than other species that already existed in the environment, and over time, they become invasive species, replacing natural species in the environment and invading new ecosystems to which they are moved. The lionfish, which is naturally found in the Pacific Ocean, has attracted the attention of researchers in recent years with its spread in different seas of the Earth. This invasive species has become prevalent in Turkey from Eastern Mediterranean to the Aegean Sea. Using and valorization of natural sources for maximum benefits are one of the important parts of sustainability goals globally. Therefore the usage of invasive marine species as an alternative for food and feed sources is a promising approach for converting a threat into benefits. This review will evaluate the potential of utilization of lionfish as a food or feed sources model for invasive species in Turkey. The proximate composition, nutritional benefits and potential risks such as bioaccumulation of heavy metals or other environmental pollutants will be criticized. The economical feasibility will also determine within previous research. The results could be useful for the food industry and fisheries science.

Keywords: Lionfish, seafood, invasive fish species, valorization, and nutritional value

INTRODUCTION

Invasive species that settle in the area where they have just moved, cause damage by competing with native species, change the balance in the ecosystem, and have negative effects on human health and economy are classified as IS. Circular Bioeconomy is defined as "the conversion of biological residues (residual) into bio-based products that can be shared/reused/reproduced, recycled or safely released into the biosphere through organic and nutrient cycles". Depending on Circular Economy and bioeconomy: some of the main aims accepted as ;prevention and reduction of urban biological waste, conversion of inevitable urban biological waste into valuable resource management, Climate change mitigation: Reducing greenhouse gas emissions by avoiding landfill and capturing carbon in bio-waste-based products, Industrial symbiosis : Linking the bio-waste and wastewater sectors with other sectors such as bio-based, chemicals, plastics, food and feed,

etc., Resource efficiency and safety: Conversion of municipal biological waste into valuable substances such as Nitrogen (N), Phosphorus (P) and Potassium (K), Sustainable food and nutrition security: Improving local food systems through bio-based solutions such as the production of feed (and ultimately food) components from urban biological waste

All species of Pterois, which belong to the family of scurvyes (Scorpaenidae), have poisonous dorsal, anal and pelvic spines (Froese and Pauly, 2019). The poison of these spines is effective enough to cause injury and death for fishermen and divers (Schofield, 2009). Due to its poisonous spines, it has few natural predators. P.miles of Indo-Pacific origin live in hard ground structures, longoses, seagrass meadows, coral reefs, artificial reefs, cliffs, muddy bottoms and sandy habitats in temperate waters deep between 1-300 feet (Khalaf and Kochzius, 2002; Albins and Hixon, 2008; Ferrieira et al., 2015). They hide on rocks and in hollows (Hare and Whitfiel, 2003).

The lesepien species entering the Mediterranean ecosystem, the evaluation of ecological niches that are not evaluated by native species, their easy population formation and the dominance on native species in bilateral competition are interpreted as an indication that this migration will be continuous (Ergüden and Doğdu, 2020). While the process is still experienced in the form of pressure of foreign species on native species, it is expected that new foreign species will replace the foreign species that have become dominant in areas where native species are found. Studies on biodiversity in the region show that this change can only be experienced in a few years (Gürlek, Erguden, Dogdu and Turan, 2016). For these reasons, the importance of combating the species that valorization of invasive species in circular economy is so important since the easiest and most functional way to combat these species is to bring the species into the economy (Zenetos et al., 2012).

VALUE-ADDED PRODUCTS FROM LIONFISH

The lionfish, whose spiny fins are poisonous, but whose meat does not contain poison, was taken to the menu of social facilities in order to spread its consumption. Lionfish are generally served after their spines are cleaned and processed into soup, grilled, steamed and fried. For the processing and consumption of an animal source as safe food; Physicochemical suitability (Nutrient composition, fat protein ratios) ,Textural properties Heavy metal, Pesticide, Pcb content should be tested to be safe in terms of Cytokoxydede and in terms of allergen.Purification of protein isolate or other biomaterial from lionfish is another alternative for processing of this species.

CONCLUSIONS

It is important to investigate the availability of fish species that show invasive characteristics in the waters of our country as functional products together with their nutritional composition, suitability for processing techniques and other food matrices. It affects the feasibility of processing during the use of invasive species as raw materials as food products, and the composition of nutrients, which differ from species to species and even from individual to individual in a bear species, leads to differences in the accumulation of aquatic pollutants in fish muscle.

The processing, packaging and introduction of invasive aquatic species, which are one of the leading environmental risk factors and which cannot have economic importance, to the aquaculture processing sector with different methods will give a new perspective to the aquaculture circular economy, which is one of the leading adequate and balanced nutrition, which has become increasingly important recently.With this application, the AIM is to hunt the existing invaders in an environment, process them and bring them to the economy and turn them into high value-added

products. The risk of invasive species moving to a new location and showing their effect there is the most important part of feasibility studies.

ABSTRACT

Origanum is a significant medicinal and aromatic plant belonging to the Lamiaceae family. In parallel with the developments in studies on the isolation and determination of various bioactive substances contained in *Origanum* species, it has been determined that they contain many different compounds. The main groups of these compounds are terpenoids, triterpene acids, hydroquinones, flavonoids, phenolic acids, hydrocarbons containing carvacrol, thymol, and various extracts as the main bioactive components. Studies on the effects of these different components against plant diseases have been the focus of attention of researchers in recent years. In studies on the impact of essential oils obtained from *Origanum* species on plant diseases, the effects of essential oils obtained from *Origanum vulgare*, *O. compactum*, *O. heracleoticum*, *O. onites*, *O. syriacum*, *O. dictamnus*, *O. acutidens*, *O. rotundifolium*, and *O. majorana* species were mostly investigated. Essential oils obtained from *Origanum* species are used as antifungal agents against *Alternaria* spp., *Aspergillus* spp., *Penicillium* spp., *Rhizopus* spp., *Fusarium* spp., *Phytophthora* spp., *Pythium* spp., *Colletotrichum* spp., *Monilinia* spp., *Geotrichum citri-aurantii*, *Verticillium dahliae*, *Botrytis cinerea*, *Plasmopara viticola*, *Sclerotium rolfsii*, *Rhizoctonia solani*, *Macrophomina phaseolina*, *Sclerotinia sclerotiorum*, *Phoma tracheiphila*, *Stemphylium beticola* and *Aphanomyces euteiches*. They also have been observed to be effective as antibacterials in research on *Clavibacter* spp., *Xanthomonas* spp., *Pseudomonas* spp., *Erwinia* spp., *Ralstonia solanacearum* and *Pectobacterium carotovorum*. The essential oils from the *O. vulgare* plant were effective against Zucchini yellow mosaic virus coat protein (ZYMV-CP) and tomato leaf curl New Delhi virus (ToLCNDV) infections. Further studies are needed to evaluate the efficacy of the model products of these essential oils.

Key words: *Origanum* spp., antifungal, antibacterial, antiviral, plant diseases

INTRODUCTION

Origanum is an important medicinal and aromatic plant belonging to the Lamiaceae family. In parallel with the developments in studies on the isolation and determination of various bioactive substances contained in *Origanum* species, it has been determined that they contain many different compounds. The main groups of these compounds are terpenoids, triterpene acids, hydroquinones, flavonoids, phenolic acids, hydrocarbons containing carvacrol, thymol and various extracts as the main bioactive components. Studies on the effects of these different components against plant diseases have been the focus of attention of researchers in recent years.

Essential oils (EO) are aromatic oily liquids obtained from various plants, generally localized in temperate and hot countries. Essential oils, as secondary metabolites in nature, play an important

role in the protection of plants as antibacterial, antiviral, antifungal and insecticide (Bakkali et al., 2008).

As observed from antifungal trials in different literature, essential oils have a great antifungal effect on many plant pathogens and have been determined to inhibit most of the plant pathogens tested in the laboratory (Omar and Kordali, 2019).

EFFECT of *Origanum* spp. ESSENTIAL OILS AGAINST FUNGAL DISEASES

Guzmán-Guzmán et al. (2003) reported that the preventive effect of various concentrations of peppermint, eucalyptus, laurel, clove, sweet marjoram, rosemary, cinnamon, pepper, grapefruit and *origanum* spp. essential oils (1,250, 2,500 and 3,750 ppm) was possible to control *Fusarium oxysporum* f. sp. *phaseoli*. Eight substances, three of which are the main components of essential oils, from Mediterranean aromatic plants (*Verbena officinalis*, *Thymus vulgaris* and *Origanum vulgare*), were tested in vitro against some phytopathogenic fungi and postharvest fruit rot agents such as *Botrytis cinerea*, *Penicillium italicum*, *P. expansum*, *Phytophthora citrophthora* and *Rhizopus stolonifer*, which were previously found to be active against them. The tested compounds, β -phellandrene, β -pinene, camphene, carvacrol, citral, o-cymene, γ -terpinene and thymol exhibited fungicidal activity (Camele et al., 2012). The essential oil and various extracts obtained from *Origanum acutidens* and methanol extracts were evaluated for their antioxidative, antimicrobial and antiviral properties obtained from callus cultures (MeOH). In particular, the essential oil exhibited strong antimicrobial activity with a significant inhibitory effect against 27 of 35 bacteria (77%), 12 of 18 fungi (67%) and tested. GC and GC-MS analyses resulted in the identification of 38 components of the oil, the main component being carvacrol. MeOH Extracts obtained from plant parts showed better antioxidative activity than butylated extracts (Sökmen et al., 2004). *Origanum onites* and other essential oils were evaluated for their antibacterial and antifungal properties. The investigated oils showed antimicrobial activity and provided antifungal activity at a high concentration of 200 μ g/mL. The fungi that *Origanum onites* is active against can be listed as follows; *Colletotrichum acutatum*, *C. fragariae* and *C. gloeosporioides* (Altintas et al., 2013). 83.37% carvacrol was observed as the main component in the essential oil obtained from *Origanum vulgare*. Germination of *Aspergillus flavus*, *A. parasiticus*, *A. terreus*, *A. ochraceus*, *A. fumigatus* and *A. niger* agents was inhibited by the obtained oil (Carmo et al., 2008; Mitchell et al., 2010). *Origanum vulgare* essential oil was found to be effective against *Colletotrichum gloeosporioides*, *F. oxysporum*, *Rhizoctonia solani*, *P. ultimum*, *Botrytis cinera* (Sun et al., 2007) (Table 1).

Plant essential oils can potentially replace synthetic fungicides in the management of postharvest fruit and vegetable diseases. This study evaluated the in vitro and in vivo activities of thymol, carvacrol, linalool and trans-caryophyllene, the single components of *Origanum vulgare* essential oil, against *Monilinia laxa*, *M. fructigena* and *M. fructicola*, which are important phytopathogens and causative agents of brown rot in pome and stone fruits before and after harvest. Furthermore, the possible phytotoxic activities of these components were evaluated and their minimum inhibitory concentrations (MICs) were determined. In vitro experiments showed that thymol and carvacrol had the highest inhibitory concentrations. The results of in vivo experiments confirmed the potent activity of thymol and carvacrol against brown rot of peach fruits. The MIC value of thymol was found to be 0.16 lg/L against *M. laxa* and *M. fructigena* and 0.12 lg/L against *M. fructicola*, while for carvacrol it was found to be 0.02 lg/L against the first two *Monilinia* species and 0.03 lg/L against the third. The results of this study showed that thymol and carvacrol can be used after appropriate formulation to control postharvest fruit diseases caused by the examined *Monilinia* species (Elshafie et al., 2015). In addition, the oil obtained from the *Origanum compactum* plant, which contains carvacrol and thymol in its components, was found to be

effective against *Alternaria alternata*, *Bipolaris oryzae*, *Fusarium graminearum*, *Fusarium equiseti*, *Fusarium verticillioides* agents (Santamarina et al., 2015) (Table 1).

It has been found to be quite successful against *Origanum majorana*, *Aspergillus niger*, *Monilinia fructicola*, *Penicillium expansum*. Its components include terpinen-4-ol, δ -2-carene, γ -terpinene, carvacrol (Della Pepa et al., 2019). *Origanum acutidens* and its components are carvacrol, thymol, p-cymene; In vitro studies against *Alternaria alternata*, *A. solani*, *Botrytis* sp., *Fusarium acuminatum*, *F. culmorum*, *F. equiseti*, *F. nivale*, *F. oxysporum*, *F. sambucinum*, *F. semitectum*, *F. solani*, *Monilinia* sp., *Pythium ultimum*, *Phytophthora capsici*, *Rhizoctonia solani*, *Sclerotinia minor*, *Verticillium dahliae* have shown that thymol and carvacrol, which contain free hydroxyl groups in the p-cymene skeleton, are more fungitoxic than p-cymene (Kordali et al., 2008) (Table 1).

In the study, an alternative to the synthetic fungicides used was sought. *Botrytis cinerea*, a destructive fungal pathogen that causes gray mold disease in tomatoes. Antifungal activities of essential oils obtained from the aboveground parts of aromatic plants belonging to the Lamiaceae family. *Origanum* (*Origanum syriacum* L. var. *bevanii*), lavender (*Lavandula stoechas* L. var. *stoechas*) and rosemary (*Rosmarinus officinalis* L.) were investigated against *B. cinerea*. It was found that the contact and volatile phase effects of different concentrations of essential oils inhibited the growth of *B. cinerea* in a dose-dependent manner. It was found that the volatile phase effects of essential oils were more effective on fungal growth than the contact phase effect. It was found that the volatile vapor of *Origanum* oil in air at 0.2 μ g/ml completely inhibited the growth of *B. cinerea* (Soylu et al., 2010).

Plasmopara viticola is the most important pathogen in vine cultivation. Alternatives to reduce fungicides are needed to ensure a fully sustainable vineyard ecosystem, consumer health and public acceptance. Essential oils are among the most promising natural plant protection alternatives and have demonstrated antibacterial, antiviral and antifungal properties in various products. In the study, grape leaves were infected with *P. viticola* and then continuously fumigated. *Origanum vulgare* essential oil was proven to be sufficient to reduce the development of the pathogen by 95% 24 hours after infection during the steam treatment (Rienth et al., 2019) (Table 1).

Legumes products such as chickpeas, lentils and dry peas are widely grown for human and animal consumption. It is quite difficult to combat pathogens that cause yield losses. Alternative methods should be resorted to due to the negative effects of fungicides used on human and environmental health. Safe and environmentally friendly plant-derived essential oils have been reported to be effective against some pathogenic fungi. Growth in essential oil supplemented growth media and inverted petri plate assay were used to determine the effects of 38 oils and their volatiles on mycelial growth and spore germination of important pathogenic fungi: *Aphanomyces euteiches*, *Botrytis cinerea*, *Colletotrichum lentis*, *Didymella pisi*, *D. rabiei*, *D. lentis*, *Fusarium avenaceum*, *Stemphylium beticola*, *Sclerotinia sclerotiorum* and *Pythium sylvaticum*. Addition of palmarosa, thyme, clove, cinnamon, lemongrass, citronella and oregano oils to the media inhibited the mycelial growth of all pathogens by 100% at 1:1,000 to 1:4,000 dilutions (Parikh et al., 2021) (Table 1).

The antioxidant and antimicrobial activities of methanol or dichloromethane extracts obtained from wild and organic culture samples of *Origanum dictamnus* were determined. Rancimate and malondialdehyde (MDA) were used to measure the antioxidant activity by HPLC methods in comparison with common commercial antioxidants butylated hydroxytoluene (BHT) and α -tocopherol. Extracts showing high antioxidant activity were encapsulated in liposomes and their antioxidant activity was estimated again by differential scanning calorimetry (DSC). Thermal-oxidative decomposition of samples (pure liposomes and encapsulated extracts) and

modification of the main transition temperature for lipid mixture and splitting of the calorimetric peak in the presence of antioxidants were also investigated by DSC method. All extracts showed antioxidant and antimicrobial activities. Their effects were proved to be superior to α -tocopherol. Methanol extract (240 ppm) of organically grown *O. dictamnus* showed higher activity than butylated hydroxytoluene. After encapsulation in liposomes, antioxidant and antimicrobial activities were proven to be higher than the same extracts in pure form (Gortzi et al., 2007) (Table 1).

In the study, in vitro antifungal activities of essential oils and their main components (carvacrol, trans-etol and 1,8-cineole) obtained from taxonomically different medicinal plants such as thyme (*Origanum syriacum* L.), fennel (*Foeniculum vulgare* Mill.) and laurel (*Laurus nobilis* L.) growing naturally in different regions of Hatay province were investigated. The effectiveness of essential oils investigated against soil-borne fungal disease agents of bean plants, *Sclerotium rolfsii*, *Rhizoctonia solani* and *Macrophomina phaseolina*, has been determined to be quite high (Türkölmez and Soylu, 2014) (Table 1).

EFFECT of *Origanum* spp. ESSENTIAL OILS AGAINST BACTERIAL DISEASES

Origanum heracleoticum, whose main component is carvacrol, has been found to be effective against fungal agents such as *Aspergillus niger*, *Botrytis cinerea*, *Monilinia fructicola*, *Penicillium expansum* and bacterial agents such as *Clavibacter michiganensis*, *Xanthomonas campestris*, *Pseudomonas fluorescens*, *Pseudomonas syringae* pv. *phaseolicola* (Della Pepa et al., 2019). *Clavibacter michiganensis* subsp. *michiganensis* (Smith) Davis et al. (Cmm) and *Ralstonia solanacearum* Yabuuchi et al. (Smith) (Rs) are important seed-borne bacterial pathogens of tomato (*Solanum lycopersicum*) listed as A2 pests in the EPPO (European and Mediterranean Plant Protection Organization) region. Currently, there are few strategies to control these pathogens and seed control with eco-compatible approaches is widely promoted. In this study, essential oils (EOs) of oregano (*Origanum vulgare*), garlic (*Allium sativum*), basil (*Ocimum basilicum*), cinnamon (*Cinnamomum zeylanicum*), clove buds (*Syzygium aromaticum*), thyme (*Thymus vulgaris*) were tested in vitro for their antimicrobial activities against Cmm and Rs. The tested essential oils caused significant inhibition of bacterial growth with very promising MBC (minimum bactericidal concentration) and MIC90 (minimum inhibitory concentration that causes 90% growth inhibition) values. Furthermore, in vivo germination test showed that there was no significant reduction in seed germination when the substances were applied as seed treatments. To test the antimicrobial activity of thyme and cinnamon oil in seed treatment in vivo, a rapid molecular screening method was developed for the specific quantification of Cmm in the presence of a plant matrix by real-time PCR without resorting to time- and space-consuming whole plant experiments (Orzali et al., 2020) (Table 1).

Hydrodistilled essential oils from *Origanum acutidens*, *O. rotundifolium* and *O. vulgare*. showed a broad spectrum of antibacterial activity on *Xanthomonas axonopodis*. At the same time, other main components such as carvacrol, thymol and terpinen-4-ol and linalool were found to have antimicrobial activity (Dadaşoğlu et al. 2011) (Table 1).

In vitro activity of *Origanum heracleoticum* L. essential oil compounds was tested against *Verticillium dahliae*, *Fusarium oxysporum*, *Phoma tracheiphila*, *Phytophthora cactorum* and *Botrytis cinerea* using four different concentrations (1×10^4 to 1×10^{-2} $\mu\text{g.ml}^{-1}$) by well diffusion method. Carvacrol and plain essential oil showed inhibitory effect against all tested pathogens at higher concentrations (Salomone et al., 2008). In this study, essential oils of four aromatic plants were tested. The compositions and antimicrobial effects of the essential oils of cinnamon (*Cinnamomum zeylanicum*), thyme (*Thymus vulgaris*), oregano (*Origanum vulgare*) and clove (*Syzygium aromaticum*) were investigated against plant pathogenic bacteria (*Pectobacterium* spp. and *Pseudomonas* spp.). Both are commonly associated with diseased fruit trees. As a result, it

was concluded that some essential oils can be used for the control of postharvest bacterial pathogens. The findings of the present study showed that essential oils have the potential to be used as antibacterial agents (Božik et al., 2017) (Table 1).

Erwinia amylovora was found to be susceptible to essential oils obtained from *Melissa officinalis*, *Mentha arvensis*, *Origanum compactum*, *O. vulgare*, *Thymus vulgaris*, *Eugenia caryophyllata*, *Mentha pulegium* plants (Kokoškova and Pavela, 2007) (Table 1).

EFFECT OF *Origanum* spp. ESSENTIAL OILS AGAINST VIRAL DISEASES

A study aimed to evaluate the antiphytoviral activity of applications with three essential oils obtained from *Origanum vulgare*, *Thymus vulgaris* and *Rosmarinus officinalis* and their corresponding hydrosols on *Zucchini Yellow Mosaic Virus* and *Tomato Leaf Curl New Delhi Virus* infected squash plants. Applications were applied after or simultaneously with virus inoculation to detect an inhibition or curative activity, respectively. Symptoms were observed and weekly samplings were done. Virus titer and expression levels of phenylalanine ammonia lyase gene (PAL) were measured in treated and untreated infected plants by real-time PCR. PAL gene plays an important role in plant defense response as it is involved in tolerance/resistance to phytopathogens. A significant inhibition was observed with *O. vulgare* essential oil and hydrosol, resulting in a 10⁻⁴ fold reduction in virus titer after 3 weeks of treatment (Taglienti et al., 2022) (Table 1).

CONCLUSIONS

In recent years, interest in the biological activities of natural compounds has been increasing due to the increasing use of fungicides that pose a risk to human and environmental health. In plant protection, essential oils are reported to exhibit antiviral, antifungal and antibacterial activities and are considered promising for the formulation of safe antimicrobial agents. Essential oils are considered as an alternative method due to their low cost and availability, and further research is required to make their use widespread.

ABSTRACT

Plants and beneficial soil bacteria engage in dynamic and reciprocal interactions that influence plant development, nutrient acquisition, and stress resilience. Among these, plant growth-promoting bacteria (PGPB) have garnered considerable attention due to their ability to support plant health through a range of biochemical and physiological mechanisms. These bacteria produce a variety of bioactive compounds that enhance plant stress tolerance, improve nutrient availability, and offer protection against phytopathogens.

PGPB influence plant performance through both direct and indirect mechanisms. Direct pathways include the biosynthesis of phytohormones (such as indole-3-acetic acid), solubilization of essential nutrients like phosphate, zinc, and potassium, ammonia production, and atmospheric nitrogen fixation. Indirectly, they contribute by secreting siderophores, lytic enzymes, hydrogen cyanide, and antibiotics, which suppress harmful microorganisms and enhance plant immunity. These functional traits position PGPB as valuable components in sustainable agriculture, especially for the development of bioformulants including biofertilizers, biopesticides, and biofungicides. Such alternatives reduce dependency on chemical inputs and contribute to environmentally responsible crop management. Nonetheless, despite the expanding repertoire of beneficial strains, the practical implementation of PGPB in agriculture remains challenging. Factors such as microbial survival, strain specificity, plant-microbiome compatibility, and fluctuating environmental conditions can influence their efficacy in field applications.

This review explores recent advances in understanding PGPB-mediated plant adaptations to abiotic and biotic stressors, with emphasis on molecular mechanisms, signaling pathways, and metabolite production. It also discusses formulation strategies and delivery systems designed to maximize their stability and performance. Ultimately, leveraging PGPB potential requires a deeper integration of microbiology, plant physiology, and environmental science to ensure their consistent and scalable use in sustainable agricultural systems.

Keywords: Plant Growth-Promoting Bacteria, stress tolerance, sustainable agriculture, biocontrol

INTRODUCTION

Through the release of bioactive chemical signals, bacteria and plants interact and communicate in a dynamic and ongoing co-evolutionary relationship. Both positive and negative interactions are possible (Wille et al., 2019). The plants gain from positive relationships because they help them acquire minerals, phytohormones, and other nutrients. By releasing a number of bioactive chemicals, these helpful bacterial species can also combat phytopathogens and help plants withstand a variety of stressful situations. Conversely, detrimental interactions are detrimental because infections infiltrate plant tissues, which causes the host plants to die (Dolatabadian, 2021; Adedayo et al., 2022). Utilizing these advantageous microbes can therefore help plants withstand stress that reduces their yield.

As part of the soil ecosystem, microorganisms have a major impact on the nitrogen cycle, soil fertility management, and plant diversity preservation. According to Zhou et al. (2020), a crucial area for important biological interactions between plants and microorganisms is the rhizosphere, a tiny area that surrounds the plant roots. Microorganisms such as bacteria, actinobacteria, fungus, algae, and protozoa aggressively compete for food and space in this productive area (Manghwar et al., 2023). Both the host and the microorganisms benefit from the ability of the plant growth promoting microorganism (PGPM) to live in and interact with plant roots; a population of rhizospheric bacteria and fungi may also serve as a home for other microbes (dos Lopes et al., 2021). The most prevalent of all the helpful microorganisms are bacteria, which are followed by fungus and actinobacteria (Poria et al., 2021). Through direct or indirect methods of nutrient absorption and assimilation, they have a beneficial effect on the plant (Kumari et al., 2018).

Food security is threatened by the world's population growth, which increases the need of fertilizers based on inorganic chemicals, which is bad for the environment and human health (Mitter et al., 2021). Because of the numerous environmental stressors that also contribute to low crop yields, organic farming that relies on microflora such as PGPM guarantees food availability while improving crop quality, productivity, and environmentally friendly farming practices (Jalal, et al., 2023). Therefore, by reducing the use of chemical fertilizers, crop production using PGPM provides sustainability and protects soil biodiversity (dos Lopes et al., 2021).

The majority of plant growth-promoting bacteria (PGPB) are proteobacteria. It includes genera like *Pantoea*, *Thiobacillus*, *Pseudomonas*, *Micrococcus*, *Rhodococcus*, *Azospirillum*, *Azotobacter*, *Acinetobacter*, *Acetobacter*, *Klebsiella*, *Enterobacter*, *Alcaligenes*, *Arthrobacter*, *Burkholderia*, *Azorhizobium*, *Achromobacter*, *Serratia*, *Bradyrhizobium*, *Flavobacterium*, *Mesorhizobium*, *Microrhizobium*, *Streptomyces*, *Bacillus*, *Azoarcus*, *Aeromonas*, *Azoarcus*, *Caulobacter*, *Chromobacterium*, *Delftia*, *Frankia*, *Flavobacterium*, *Gluconacetobacter*, *Paenibacillus*, *Rhizobium* and *Streptomyces* (Table 1).

In addition to helping plants tolerate a variety of biotic and abiotic stressors, the PGPB also promotes plant growth by promoting the solubility of various inorganic mineral nutrients, fixing nitrogen, releasing plant growth regulators, and producing a number of other biochemicals that either directly or indirectly increase plant productivity. Figure 1 shows the several ways that bacteria can promote plant growth.

Table 1. Plant growth promoting bacteria and their common host plant family (from Fanai et al., 2024).

Family	Plant	Plant growth-promoting bacteria
Fabaceae	<i>Phaseolus vulgaris</i>	<i>Rhizobium acidisoli</i> , <i>R. endophyticum</i> , <i>R. esperanzae</i> , <i>R. etli</i> , <i>R. hidalgoense</i> , <i>R. mesoamericanum</i> , <i>R. tropici</i> , <i>Acinetobacter</i> sp.
Poace	Rice, wheat, maize, sorghum, sugarcane	<i>Azospirillum</i> sp.
Asteraceae	Puticaria	<i>Bacillus cereus</i> , <i>Agrobacterium fabrum</i> , <i>Brevibacillus brevis</i> , <i>Bacillus subtilis</i> , <i>Paenibacillus</i> sp., <i>Acinetobacter radioresistant</i> , <i>Burkholderia</i> sp.
Solanaceae	<i>Artemisia annua</i>	<i>Brevibacillus</i> sp., <i>Bacillus</i> sp., <i>Pseudomonas</i> sp., <i>Azospirillum</i> sp., <i>Klebsiella</i> sp., <i>Enterobacter</i> sp., <i>Alcaligenes</i> sp., <i>Azotobacter</i> sp., <i>Streptomyces</i> sp., <i>Pantoea</i> sp., <i>Bacteroides</i> sp., <i>Proteobacteria</i> sp., <i>Radiobacter</i> sp., <i>Stenotrophomonas</i> sp.
Brassicaceae	<i>Brasica oleraceae</i>	<i>Pseudomonas</i> sp., <i>Enterobacter</i> sp., <i>Arthrobacter</i> sp., <i>Pantoea</i> sp.
Crasulaceae	<i>Echevari laui</i>	<i>Erwinia</i> sp., <i>Pantoea</i> sp.

Figure 1. Functions that plant growth-promoting bacteria provide. The impacts of both biotic (caused by living things) and abiotic (induced by environmental variables) stress on plants demonstrate how PGPB helps to lessen the effects of stress. Through processes including siderophores, lytic enzymes, HCN, antibiotics & nitrogen fixation, hormone synthesis, etc., PGPB improve plant development, nutrient absorption, and stress tolerance (from Fanai et al., 2024).

One possible approach to a sustainable future is the use of helpful microorganisms as bioinoculants in agricultural systems. As an effective, environmentally friendly, and productive fertilizer that could help meet the growing demand for food from the world's population, it is a

good substitute for chemical fertilizers. They improved the soil microbiota and preserved soil fertility in addition to promoting plant growth.

ABIOTIC AND BIOTIC STRESS FACTORS

Continuously subjecting plants to biotic and abiotic stressors has a negative effect on their growth and development, which lowers yield and quality (Singh et al., 2021). With the help of a naturally occurring PGPB that increases resistance against different phytopathogens by generating biochemicals and improving soil fertility, plants subsequently develop particular kinds of defense mechanisms for stress response (Leontidou et al., 2020). Figure 2 shows the various stressors and bacterial stress tolerance systems.

Figure 2. Various stressors and bacteria that support plant growth react to provide plant growth promotion. The impacts of both biotic (caused by living things) and abiotic (induced by environmental variables) stress on plants demonstrate how PGPB helps to lessen the effects of stress. By means of processes like nitrogen fixation, hormone synthesis, and biocontrol, PGPB improve plant growth, nutrient absorption, and stress tolerance (from Fanai et al., 2024).

Drought stress is categorized into hydrological, socio-economic, meteorological, and agricultural types, each leading to soil moisture deficits and the accumulation of reactive oxygen species that damage plant structure and function (Ahluwalia et al., 2021). Traditional mitigation measures—such as biochar amendments, nanoparticle treatments, film farming, and drought-resistant cultivars—have shown only limited benefits in real agricultural systems (Fadiji et al., 2022). By contrast, plant growth-promoting bacteria (PGPB) enhance drought tolerance through improved water uptake, root architecture modification, and production of protective phytochemicals (Khan and Bano, 2019). For example, inoculation with *Bacillus pumilus* and

Pseudomonas putida improved maize drought resilience and nutrient acquisition (Kálmán et al., 2024), while *Bacillus subtilis* and *Azospirillum brasilense* increased osmolyte synthesis to support wheat germination under water deficit (Ilyas et al., 2020). Strains such as *Pseudomonas lini* and *Serratia plymuthica* enhance soil aggregate stability, and *Bacillus albus* together with *Bacillus cereus* boost seed vigor, pigment concentration, and antioxidant activity, collectively strengthening photosynthetic efficiency and stress defenses (Zhang et al., 2020; Ashry et al., 2022; Saleem et al., 2021). Other notable drought-tolerant bacteria include *Achromobacter xylosoxidans*, *Pseudomonas aeruginosa*, *Lelliottia adecarboxylata*, *Enterobacter cloacae*, *Pseudomonas fluorescens* S3X, and *Staphylococcus sciuri* (Danish et al., 2020; Khalilpour et al., 2021).

A rise in average global temperatures poses a significant abiotic challenge for crop productivity (Desaint et al., 2021). Heat-tolerant microbes—including *Bacillus cereus*, *Serratia liquefaciens*, *Pseudomonas putida*, *P. fluorescens* (Mitra et al., 2021), *Burkholderia phytofirmans*, *Curvularia protuberata* (Rana et al., 2021), *Paraburkholderia phytofirmans*, and various *Bacillus* and *Pseudomonas* spp. (Ahmad et al., 2023)—mitigate thermal damage by modulating plant hormone levels (e.g., cytokinins, ACC deaminase) and activating antioxidant enzymes that control water uptake and induce heat-shock protein expression (Moumbock et al., 2021). Exogenous application of specific amino acids further alleviates heat-stress effects by enhancing stress-responsive pathways (Santos et al., 2022). Inoculation with *B. cereus* has been shown to boost overall biomass, chlorophyll content, and heat-shock protein accumulation (Khan et al., 2020b), while *Enterobacter* sp. SA187 increased wheat and *Arabidopsis* heat endurance, leading to higher grain yield, plant height, and seed weight. Moreover, *B. cereus* enhances carotenoid, protein, ascorbate peroxidase, chlorophyll, and superoxide dismutase levels (Bisht and Mishra, 2020), and strains such as *B. thuringiensis*, *B. subtilis*, *P. brassicacearum* (Ashraf et al., 2019), and *B. velenzensis* further demonstrate the promise of microbial inoculants for improving plant thermotolerance.

Soil salinization, driven by water scarcity and the accumulation of NaCl-rich compost from sewage and waste treatment, and the build-up of soluble ions—bicarbonate, magnesium, sodium, chloride, sulfate, carbonate, and calcium—alters soil composition, diminishes fertility, impairs germination, and disrupts chloroplast structure, leading to reduced pigment synthesis, ion toxicity, and osmotic imbalance (Ahmed et al., 2020; Krishnamoorthy et al., 2022). Salinity stress further reduces plant development, fruit yield, biomass, stomatal conductance, and water movement (Ansari et al., 2019). Plant growth-promoting bacteria counteract these adverse effects by inducing stress-responsive pathways that lower reactive oxygen species production, synthesizing Na⁺-binding exopolysaccharides, and producing phytohormones to enhance root growth and water uptake (Subramaniam et al., 2020). For instance, *Bacillus amyloliquefaciens* GB03 releases volatile organic compounds that boost stress mitigation sixfold (Cappellari et al., 2020). Additionally, halotolerant strains of *Streptomyces*, *Aneurinibacillus aneurinilyticus*, *Paenibacillus* spp., *Pseudomonas azotoformans*, and other genera such as *Bacillus*, *Enterobacter*, *Klebsiella*, *Agrobacterium*, and *Ochrobactrum* can tolerate NaCl up to 150 g/L, highlighting their promise in reclaiming saline soils (Liu et al., 2021).

Plant growth-promoting microbes (PGPM) suppress biotic stresses from pathogenic fungi, bacteria, nematodes, insects, and weeds by activating systemic acquired resistance (SAR) and induced systemic resistance (ISR). SAR arises when PGPM directly inhibit pathogens, whereas ISR is triggered by bacterial elicitors such as volatile organic compounds (VOCs), microbe-associated molecular patterns (MAMPs), and bioactive secondary metabolites (Dubey et al., 2020). These microbes employ lytic enzymes, antibiotics, and VOCs for direct antagonism and enhance plant defenses indirectly through nitrogen fixation, siderophore production, phosphate solubilization, and phytohormone signaling (Migunova and Sasanelli, 2021). For instance, *Pasteuria penitans* and *Brevibacillus laterosporus* secrete proteases that inhibit *Heterodera glycines* (Mohan et al., 2020), while *Bacillus megaterium* combats *Meloidogyne graminicola* similarly. Strains like *Pseudomonas aeruginosa*, *P. cepacia*, and *P. fluorescens* exhibit broad-

spectrum antimicrobial and anthelmintic activities (Bhavya and Geetha, 2021), and *Bacillus subtilis* and *B. pumilus* produce chitinases and antifungal VOCs that disrupt nematode chitin synthesis. *Bacillus amyloliquefaciens* FZB42 and *Arthrobacter nicotianae* release bacteriocins and VOCs that inhibit *Meloidogyne* spp. By colonizing the rhizosphere and producing siderophores, phytohormones, and antibiotics, PGPM also inhibit soil-borne fungi, solubilize phosphate, and promote plant growth via indole-3-acetic acid synthesis. These combined actions outcompete pathogens for nutrients and induce ISR against bacterial genera—such as *Erwinia*, *Pectobacterium*, *Pantoea*, and *Xanthomonas*—that cause wilts, blights, galls, and root rots (Nazari and Smith, 2020; Nabila and Kasiamdari, 2021).

Table 2. Overview of Plant Growth-Promoting Rhizobacteria functions (from Priyanka et al., 2020)

Function of PGPR	Description	PGPR strain
Nitrogen fixation	Conversion of free atmospheric nitrogen into oxide form that can be used	<i>Enterobacter</i> , <i>Klebsiella</i> , <i>Burkholderia</i> , and <i>Stenotrophomona</i>
Phosphate solubilization	Conversion of insoluble phosphate into the soluble form absorbed by the plants	<i>Achromobacter</i> , <i>Agrobacterium</i> , <i>Bacillus</i> , <i>Enterobacter</i> , <i>Erwinia</i> , <i>Escherichia</i> , <i>Flavobacterium</i> , <i>Mycobacterium</i> , <i>Pseudomonas</i> and <i>Serratia</i>
Potassium solubilization	Conversion of potassium in the useful form	<i>Acidithiobacillus ferrooxidans</i> , <i>Bacillus edaphicus</i> , <i>Bacillus mucilaginosus</i> , <i>Burkholderia</i> , <i>Paenibacillus</i> sp. and <i>Pseudomonas</i>
Production of siderophore	Enhancing the source of iron in the soil that can be absorbed by the plants	<i>Aeromonas</i> , <i>Azadirachta</i> , <i>Azotobacter</i> , <i>Bacillus</i> , <i>Burkholderia</i> , <i>Pseudomonas</i> , <i>Rhizobium</i> , <i>Serratia</i> and <i>Streptomyces</i> sp.
Phytohormone production	Production of phytohormones such as auxin, cytokinins, gibberellic acid and ethylene	<i>Azotobactersp.</i> , <i>Rhizobium</i> sp., <i>Pantoea agglomerans</i> , <i>Rhodospirillum rubrum</i> , <i>Pseudomonas fluorescens</i> , <i>Bacillus subtilis</i> and <i>Paenibacillus</i> sp.

DIRECT AND INDIRECT MECHANISMS OF PGPB IN ENHANCING PLANT PERFORMANCE

Indirect mechanisms

Siderophore production: Bacteria secrete ferric-specific ligands (hydroxamates, phenolates, carboxylates) to solubilize iron for themselves and host plants, enhancing root colonization and outcompeting pathogens; common producers include *Bacillus*, *Chryseobacterium*, *Phyllobacterium*, and *Pseudomonas* spp. (Bhatt et al., 2019).

Protease secretion: Microbial proteases (alkaline, acidic, neutral)—notably from *Bacillus* spp.—hydrolyze pathogen proteins and generate antifungal metabolites (e.g., serine proteases,

subtilisins), serving as an indirect plant defense; activity is screened on skim-milk agar by clear halo formation (Castaldi et al., 2021).

Catalase activity: Catalase-positive strains (e.g., *Bacillus marinus*, *B. sphaericus*, *Staphylococcus aureus*) detoxify H₂O₂ at root interfaces, mitigating oxidative damage under stress; detected by bubble formation in 3% H₂O₂ (Talaiekhazani, 2022).

Amylase production: Alpha-amylases from endophytes like *Bacillus amyloliquefaciens* and *B. licheniformis* degrade pathogen cell walls and contribute to industrial applications (detergents, stain removal); screened on starch agar via iodine-stained halos (Ismail et al., 2021).

Urease activity: Ureolytic bacteria hydrolyze urea into plant-available ammonium and nitrates, supporting nitrogen nutrition and biomineralization (soil enrichment, concrete repair); measured by pH-dependent color change in urea broth (Cui et al., 2022).

Hydrogen cyanide (HCN) release: Rhizobacteria (mostly *Pseudomonas* and *Bacillus* spp.) emit HCN to inhibit fungi, nematodes, insects, and weeds without harming the host plant; detected via alkaline-picric acid colorimetric assay (Alemu, 2016).

Table 3. Mechanisms and functions of PGPB (adapted from Olanrewaju et al. (2017) and Fanai et al. (2024))

Mechanism	Category	Primary Function	Reference
Indole-3-acetic acid (IAA)	Direct	Stimulates root initiation, cell division, lateral root formation	Olanrewaju et al. (2017)
ACC deaminase activity	Direct	Degrades precursor of ethylene; alleviates abiotic-stress inhibition	Olanrewaju et al. (2017)
Cytokinin production	Direct	Promotes shoot growth, delays leaf senescence	Fanai et al. (2024)
Nitrogen fixation	Direct	Converts atmospheric N ₂ into bioavailable NH ₄ ⁺	Fanai et al. (2024)
Phosphate solubilization	Direct	Releases organic acids to convert insoluble P into plant-available forms	Fanai et al. (2024)
Siderophore production	Indirect	Sequesters Fe ³⁺ , suppresses pathogen growth, improves iron nutrition	Olanrewaju et al. (2017)
Lytic enzyme secretion	Indirect	Produces chitinases/proteases to degrade fungal and nematode walls	Olanrewaju et al. (2017)
Hydrogen cyanide (HCN) emission	Indirect	Volatile compound that inhibits soil-borne pathogens and weeds	Olanrewaju et al. (2017)
Antibiotic metabolite release	Indirect	Synthesizes antimicrobial compounds against bacteria and fungi	Olanrewaju et al. (2017)
Induced systemic resistance (ISR)	Indirect	Elicits plant defense pathways via MAMPs and VOCs	Fanai et al. (2024)

Direct mechanisms

Phytohormone production: Plant growth-promoting bacteria (PGPB) synthesize cytokinins, gibberellins, and especially indole-3-acetic acid (IAA), which regulate cell division, root initiation, and stress responses. Strains such as *Paenibacillus polymyxa*, *Rhizobium leguminosarum*, *Pseudomonas fluorescens* produce cytokinins (Mekureyaw et al., 2022), while *Bacillus pumilus* and *B. licheniformis* generate multiple gibberellins (Gutiérrez-Mañero et al., 2001). IAA producers, including *Azospirillum*, *Arthrobacter*, *Bradyrhizobium*, *Pantoea*, *Rahnella*, and *Enterobacter*, enhance root elongation and nutrient uptake (Rehman et al., 2020).

Phosphate solubilization: PSB release organic acids (citric, gluconic) that chelate cations and convert insoluble phosphates (tricalcium, rock phosphate) into bioavailable forms. Key taxa include *Pseudomonas putida*, *Azospirillum lipoferum*, *Bacillus firmus*, *B. polymyxa*, *Serratia*

marcescens, and *Arthrobacter aureofaciens*. PSB inoculation boosts phosphorus availability and activates stress-responsive genes in crops like potato and sugarcane (Lin et al., 2023).

Ammonia production: Ammoniogenic PGPB such as *Pseudomonas putida*, *Klebsiella* spp., and *Enterobacter asburiae* generate NH_3 , raising soil pH to suppress pathogens and supply inorganic nitrogen, which enhances root/shoot growth and biomass (Gohil et al., 2022).

Nitrogen fixation: Symbiotic genera (*Bradyrhizobium*, *Mesorhizobium*, *Sinorhizobium*, *Azorhizobium*, *Neorhizobium*) and free-living diazotrophs (*Azotobacter*, *Azospirillum*, *Burkholderia*, *Pseudomonas*, cyanobacteria) convert atmospheric N_2 into plant-available forms, supporting growth and yield (Basile and Lepek, 2021). Microbial consortia of *B. subtilis* and *A. brasilense* enhance root/shoot development, gas exchange, and grain yield in wheat, while co-inoculation of *Bradyrhizobium* and *Bacillus* improves nodulation and *Vigna unguiculata* productivity (Galindo et al., 2024; Gaspareto et al., 2023).

Zinc solubilization: Zinc is a vital enzyme co-factor, with optimal plant tissue levels at 30–100 $\text{mg}\cdot\text{kg}^{-1}$; deficiency impairs growth and causes necrotic lesions. Zinc-solubilizing bacteria secrete organic acids and iron-chelating enzymes to lower rhizosphere pH and release Zn^{2+} (Eshaghi et al., 2019). Key taxa include *Pseudomonas aeruginosa*, *Gluconacetobacter diazotrophicus*, *P. striata*, *P. fluorescens*, *Burkholderia cenocepacia*, *Serratia liquefaciens*, *S. marcescens*, *Bacillus thuringiensis*, *B. aryabhattai*, *B. subtilis*, *Thiobacillus thiooxidans*, and cyanobacteria. *Rhizobium*, *Pseudomonas*, and *Bacillus* spp. enhance Zn translocation and grain biofortification, improving wheat quality via exopolysaccharide and siderophore production (Jalal et al., 2024). Co-inoculation of *B. subtilis* or *P. fluorescens* with foliar ZnO further boosts maize chlorophyll, amino acids, glutelin, and prolamin content. Bacterial Zn nanoparticles inhibit biofilm formation in pathogens and augment human oral microbiome antimicrobial activity (Lallo da Silva et al., 2019).

Figure 3. Overview of the main mechanisms used by PGPB to improve plant growth (from Vuolo et al., 2022)

Potassium solubilization: Although abundant in soils, K often exists in insoluble forms; PGPB release organic acids (citric, oxalic, tartaric) to chelate and solubilize K⁺, facilitating uptake (Olaniyan et al., 2022). Potassium activates over 60 plant enzymes, regulates stomatal dynamics, enhances disease resistance, fiber strength, and produce quality, and mitigates water-stress sensitivity (Rawat et al., 2022). Notable K-solubilizers include *Acidithiobacillus*, *Burkholderia*, *Pseudomonas* spp., *Bacillus megaterium*, *Arthrobacter*, *Pantoea ananatis*, *Rahnella aquatilis*, *Enterobacter* sp., *Bacillus/Paenibacillus mucilaginosus*, *Bacillus licheniformis*, *P. azotoformans*, *B. edaphicus*, and *Pseudomonas putida* (Bakhshandeh et al., 2017).

CONCLUSION

Plant growth-promoting bacteria represent a cornerstone of sustainable agriculture by naturally supplying key metabolites—phytohormones, siderophores, lytic enzymes, hydrogen cyanide, and ammonia—and by solubilizing essential nutrients (P, Zn, K) or fixing atmospheric nitrogen. Their multifaceted modes of action not only enhance crop yield and quality under both biotic and abiotic stresses but also reduce reliance on synthetic agrochemicals, thereby protecting soil health and the broader environment.

To translate this promise into practice, future work must prioritize the development and field-ready formulation of robust biofertilizers and biocontrol agents tailored to specific crops and stress conditions. Equally critical is the systematic evaluation of PGPB–host compatibility to safeguard beneficial traits during root colonization, as well as the design of microbial consortia whose members coexist synergistically without compromising individual functionality. Addressing these challenges will pave the way for precision applications of PGPB, driving both productivity gains and ecological resilience in modern farming.

ABSTRACT

Ants (Family Formicidae) are essential eusocial insects crucial for ecosystems, often used as environmental indicators due to their sensitivity to ecosystem changes. This study examines the specific role of the species *Cataglyphis nodus* (Brullé, 1833), known for its adaptation to dry and high-temperature environments, within the wetland ecosystem of Narta Lagoon, an internationally important Protected Area in Albania. Through sampling with "Pitfall Traps" at 11 stations during June-July 2025, we analyzed the distribution of *C. nodus* based on soil moisture, soil type, vegetation, and anthropogenic impacts. The results clearly showed that the highest density of individuals was found in areas with sandy/gravelly, dry soil and herbaceous vegetation. Zones with agricultural activities and those used as pastures also showed a high presence, suggesting that human interventions might create suitable habitats for this xeric species. This highlights its role as a valuable ecological indicator in the lagoon ecosystem, signaling xeric (drought) conditions, open and sandy microhabitats, and anthropogenic impact. In conclusion, *C. nodus* is an important indicator species for monitoring drought trends, changes in habitat structure, and assessing the impact of human activities in lagoon ecosystems. Continued studies of this nature are recommended to gain clearer information on ecosystem adaptations and their services to climate change.

Keywords: Formicidae, indicators, ecological, xeric species, *Cataglyphis nodus*, lagoon.

INTRODUCTION

The family Formicidae, commonly known as ants, is a diverse and successful group of eusocial insects belonging to the order Hymenoptera. Ants are a dominant group of insects in many terrestrial habitats and play a key role in the functioning of ecosystems. Ants are extremely adaptable and successful insects, and their study has provided deep insights into social behavior, communication, and ecology. As predators, scavengers, seed dispersers, and ecosystem engineers, changes in ant populations can reflect larger changes in ecosystem functioning. Different ant species have different levels of tolerance to environmental changes (Tibcherani et al., 2018). Some are "opportunistic" species that thrive in altered environments, while others are "specialists" that are sensitive to disturbances. These characteristics make formicidae good indicators of environmental change and indicators of microhabitat conditions (Keshamma 2022). *Cataglyphis nodus* (Brullé et al., 1833) is a species of ant known to survive and thrive in extreme, arid environments (Agosti et al., 1990). It is able to physiologically adapt to harsh conditions, especially high temperatures (Boulay et al., 2017). This species is mainly found in arid and semi-arid regions of the Mediterranean basin, the Middle East and North Africa. They prefer sandy,

gravelly or clayey soils with good drainage, where they can build their underground nests (CERDA 2013). *Cataglyphis nodus* favors open habitats, with little dense vegetation, which allows maximum exposure to sunlight and increased surface temperatures. This makes them common in dunes, dry grasslands and degraded areas. They are among the few species that are active and hunt during the hottest hours of the day, tolerating ground temperatures that often exceed 50°C, when most other creatures hide. Their long legs help them keep their bodies off the hot ground. They have also developed specific hydrocarbons in their cuticle that minimize water loss and protect them from dehydration. They move at high speed and in an irregular manner to minimize contact time with the hot ground, and often seek out small objects such as leaves or pebbles to cling to and cool off for a few moments. They feed mainly on dead insects and other arthropods, which have often died from the heat. This makes them important scavengers in desert ecosystems. They may also consume live insects, as well as other food sources such as nectar, seeds, depending on availability. Due to their specific requirements for dry and hot environments, the presence and density of "*Cataglyphis nodus*" can serve as an indicator of xeric (drought) conditions, habitat degradation (creation of open and exposed areas), and the impact of anthropogenic activities (such as grazing or agriculture that favor dry and open lands) within ecosystems that may normally be wetter, as is the case with wetland ecosystems (antwiki.org). Overall, "*Cataglyphis nodus*" is an interesting species that highlights the power of natural adaptation to environmental challenges and provides valuable data on the health and changes of the ecosystems where it is found.

MATERIALS AND METHODS

Study Area

The Narta Lagoon is a key wetland ecosystem in Albania, of great national and international importance. Located north of the city of Vlora, it covers an area of approximately 42 km² and is part of the "Pishë Poro – Nartë" Protected Landscape, as well as the "Karaburun-Sazan" National Marine Park (Protected Landscape "Vjosë-Nartë").

Narta is an area of particular importance for biodiversity. It has been declared a Ramsar Wetland (a wetland of international importance), as well as an Important Bird Area (IBA) (Bino et al., 2019). These statuses reflect its high ecological value.

As a coastal lagoon, Narta is characterized by brackish and semi-braked waters, which are influenced by the connection to the Adriatic sea and the freshwater inflows from small streams and canals. Its depth is generally shallow, which creates ideal conditions for many aquatic and wetland species.

The lagoon is a key resting and feeding point for thousands of migratory birds, including globally endangered species such as the flamingo and the dalmatian pelican. It also supports a rich variety of fish, amphibians, reptiles and mammals (Saçdanaku et al., 2020).

The plant landscape around Narta is diverse. In addition to typical wetland vegetation such as reedbeds, there are also areas with halophilic (salt-tolerant) vegetation, Mediterranean shrubs, sandy areas (dunes) and areas with herbaceous vegetation, especially on the outskirts and small islands (Meço et al., 2024).

Despite its protected status, the lagoon is affected by human activities such as traditional fishing, livestock grazing, and agricultural activities in the surrounding areas. These impacts can cause changes in habitats and pose challenges to sustainable ecosystem management.

Fig.1 Map of the study area and sampling points

As an area with a mediterranean climate (hot, dry summers), the Narta Lagoon and its coastal areas exhibit interesting interactions with drought-adapted species, such as *Cataglyphis nodus*, which serve as potential indicators of microhabitat shifts towards more xeric conditions.

Sampling method

Sampling was carried out at 11 stations (St.I to St.XI) within the lagoon ecosystem of the Narta lagoon. Sampling was carried out during June and July 2025. The method used for sampling is “Pitfall Traps” (Borowiec et al., 2022). The method consists of placing cups or containers on the ground, with the rim level with the ground surface (Jiménez-Carmona 2020). A preservative solution (water with detergent, 70-95% ethyl alcohol, or propylene glycol) is placed inside to capture and preserve the ants that fall inside. The traps are fitted with a small cover that can be placed on top of the trap to prevent rainwater from entering and reduce evaporation (antwiki.org). The determination of the samples was carried out based on the determination keys for the family formicidae for the European region (Key to *Cataglyphis* of Greece).

Fig.2 Sampling stations

Fig.3 Photo during laboratory determinations

RESULTS AND DISCUSSION

Data Analysis

Based on the data analysis, the following conclusions were reached (Table 1):

Station IV stands out immediately with 38 individuals (0.372%), while the other points have significantly lower numbers (2-12 individuals). This point is sandy, has herbaceous vegetation with few pine trees and is partially dry. This matches well with the preferences of *Cataglyphis nodus*.

Stations IX and X have sandy and clayey/gravelly soil, herbaceous vegetation, and are areas used as pastures. The soil moisture condition is "dry". These characteristics are very favorable for *Cataglyphis nodus*.

Station XI has sandy soil, herbaceous vegetation and agricultural trees, has agricultural activities and is "dry". This point also meets many of the ants' requirements.

Stations II and III, although "dry" and with pine forest, are clayey (not ideal) and have low numbers of individuals. The forest fire at St.III may have changed the conditions (perhaps making it more open and hotter) but the fact that the soil is clay remains a disadvantage.

Stations V and VI are sandy but "wet", explaining the low numbers.

Station VIII is sandy and clay, with vegetation and pine forest, and dry. We would expect more individuals here based on the dryness, but perhaps the dense pine forest vegetation affects things differently.

Table 1. General data collected in the field

Sampling Point	No. of Individuals	D (%)	Soil Type	Vegetation Types	Observations on Pollution/Changes	Soil Moisture Condition
St.I	6	0.06%	Clay	Herbaceous	No	Moist
St.II	4	0.04%	Clay	Pine Forest	No	Dry
St.III	2	0.02%	Clay	Pine Forest	No (forest burned a few years ago)	Dry
St.IV	38	0.37%	Sandy	Partially Pine and Herbaceous Vegetation	No	Partially Dry
St.V	5	0.05%	Sandy	Pine Forest and Herbaceous Vegetation	No	Moist
St.VI	5	0.05%	Sandy	Herbaceous Vegetation	No	Moist
St.VII	2	0.02%	Sandy	Herbaceous Vegetation	Moist, with water during the winter season	Moist
St.VIII	5	0.05%	Sandy and Clay	Herbaceous Vegetation and Pine Forest	Area used as pasture	Dry Soil
St.IX	12	0.12%	Sandy and Clay	Herbaceous Vegetation	Area used as pasture	Dry Soil
St.X	12	0.12%	Gravelly and Clay	Herbaceous Vegetation	Area used as pasture	Dry Soil
St.XI	11	0.11%	Sandy	Herbaceous Vegetation and Agricultural Trees	Agricultural activities	Dry

Analysis of the distribution of *Cataglyphis nodus* according to soil moisture condition

To assess the impact of moisture, the stations were grouped according to moisture condition and the average number of individuals was calculated:

Wet: Average individuals 4.5 (St.I, St.V, St.VI, St.VII)

Partially dry: Average individuals 38 (St.IV)

Dry: Average individuals 7.67 (St.II, St.III, St.VIII, St.IX, St.X, St.XI)

This distribution shows a clear trend: the points with lower humidity (partially dry and dry) exhibit a significantly higher number of *Cataglyphis nodus* individuals, with St.IV significantly dominating in this respect. Although the "dry" stations have a lower average than St.IV, they are the group with the second highest density, highlighting the preference for dryness.

Analysis of *Cataglyphis nodus* distribution by soil type

To understand soil preferences, stations were analyzed by substrate type:

Clay: Average of individuals 4 (St.I, St.II, St.III)

Sandy: Average of individuals 12.2 (St.IV, St.V, St.VI, St.VII, St.XI)

Sandy and Clay: Average of individuals 8.5 (St.VIII, St.IX)

Gravel and Clay: Average of individuals 12 (St.X)

The results show that soil types with sandy or gravelly content (Sandy, Sandy and Clay, Gravel and Clay) support larger populations of *Cataglyphis nodus* compared to clay soils. This is in line with the ecological requirements of desert species that prefer soils with good drainage and high drying rates.

Analysis of the impact of vegetation and anthropogenic changes

Herbaceous Vegetation: Stations with high numbers of individuals (St.IV, St.IX, St.X, St.XI) display dominant herbaceous or mixed vegetation. This indicates a preference for open areas, where sunlight can warm the soil surface without obstacles, a key requirement for thermophilic species.

Anthropogenic Impacts: The high-density points (St.IX, St.X) are located in areas used as pastures, and St.XI has agricultural activities. These activities may contribute to the creation of a more open and potentially drier habitat, favoring the presence of *Cataglyphis nodus* through the reduction of plant cover and exposure of the soil surface. The observation at St.III of the "burnt forest" suggests a change in habitat, but the clayey nature of the soil and the possible residual moisture may have limited the number of individuals.

Analyzing the Role of *Cataglyphis nodus* as an Ecological Indicator

Based on the above analyses, *Cataglyphis nodus* appears as a valuable ecological indicator in the wetland ecosystem, signaling the following directions.

Indicator of xeric conditions:

The presence and high density of *Cataglyphis nodus* is directly related to "dry" or "semi-arid" soil conditions. This suggests that areas with large populations of this species are experiencing habitat drying and may be under the influence of climatic or hydrological changes leading to more xeric conditions.

Indicator of open and sandy microhabitat:

The species' preference for sandy/gravelly soils and areas with herbaceous vegetation indicates that they serve as indicators of open, sun-exposed, and rapidly draining microhabitats. This is particularly significant within a wetland ecosystem that is typically characterized by humidity.

Anthropogenic Impact Indicator: High density in areas of pastures and agricultural activities suggests that human interventions may create or expand suitable habitats for *Cataglyphis nodus*, altering the local ecosystem.

CONCLUSIONS AND RECOMMENDATIONS

Sampling data clearly show that *Cataglyphis nodus* prefers and is found in dry, sandy and open microhabitats within the wetland ecosystem. This makes it an important indicator species for:

- Monitoring drought or desertification trends in coastal areas.
- Identifying changes in habitat structure that favor xeric species.
- Assessing the impact of human activities such as grazing and agriculture on the ecosystem.

The presence and high density of *Cataglyphis nodus* is directly related to "dry" or "semi-arid" soil conditions. The species' preference for sandy/gravelly soils and areas with herbaceous vegetation indicates that they serve as indicators of open, sun-exposed and rapidly draining microhabitats. This is particularly significant within a wetland ecosystem that is typically characterized by humidity

The use of environmental indicators provides us with clearer information on long-term environmental conditions and the state of microhabitats.

This study provides a solid basis for understanding the ecological role of *Cataglyphis nodus* and

their interaction with environmental conditions in a wetland ecosystem.

To protect our ecosystems in the future, it is recommended to continue such studies, as we obtain clearer information on ecosystem adaptations related to climate change.

ABSTRACT

In Giresun, one of the important fishing cities of the Black Sea with a total coastline of 122 km, the fishing gears used intensively in small-scale fishing are gillnet and trammel net and various hand lines. With these, fish species such as whiting, turbot, horse mackerel, anchovy, red mullet, garfish, bluefish are mainly caught. In addition, trout production is also abundant in the pools along the rivers in the region. The present study was conducted in the central district of Giresun with the objective of ascertaining the present status of fishery cooperatives and certain socio-demographic characteristics of fishermen, in addition to the problems with which they are confronted. The present study was conducted in the fishing ports of Giresun Fishery Cooperative, Üçkayalar Fishery Cooperative and Aksu Neighbourhood Fishery Cooperatives between October 2023 and April 2024. Thirty-two fishermen were interviewed in person. The participants were boat owners who were members of cooperatives in the ports. The status of fishery cooperatives in the region was determined, as were the regional fisheries and problems.

Keywords: Small-scale fisheries, marketing, cooperative, Eastern Black Sea

INTRODUCTION

As in all Eastern Black Sea cities, fishing is one of the most important occupations for the local population. Fishing in Giresun is conducted in a coastal manner, based on observing schools of fish. Anchovy, whiting, turbot, horse mackerel, sea bream, scorpionfish, red mullet, grey mullet, bluefish, and bonito are the most commonly targeted fish species. 3% of the total registered fishing vessels in our country are in Giresun, and a total of 563 boats operate in the fishing sector throughout the province, 545 of which are between 0-12 m in length and 18 of which are >12 m in length (Erdoğan Sağlam and Çalık, 2016a).

Fisheries cooperatives are a form of organization that brings together stakeholders engaged in fishing, processing, aquaculture, or marketing activities within the sector. These cooperatives are focused on the development of the fishing industry and the improvement of fishermen's welfare. They aim to increase income, improve living standards, and increase production. Their primary purpose is to rationally and economically meet and provide for the professional and livelihood needs of individuals lacking sufficient financial resources through mutual aid, solidarity, and guarantees (Ünal and Yercan, 2006).

The Black Sea Region, where fishing is widespread, accounts for 75% of the fish production (TRGM/TEPGE, 2024). Eastern Black Sea region is providing 58% of total production. Giresun is one of the most important fishing centers of the Eastern Black Sea Region. There are not many studies on the status of the fisheries cooperatives and fishermen operating in the city center. Some studies have been found on a general overview of fisheries in Giresun (Erdoğan Sağlam and Çalık, 2016a), an examination of fisheries associations and

cooperatives in Giresun (Erdoğan Sağlam and Çalık, 2016b), an economic analysis of fishing activities in Giresun (Mutlu et al., 2018), and the fishing coastal structures of Giresun Province (Tokmak Kırkses and Samsun, 2020). The purpose of this study is to examine the functioning of three fisheries cooperatives located in the central district of Giresun, to determine some socio-demographic characteristics of fishermen, and to identify current problems of the fishermen and cooperatives.

MATERIAL AND METHOD

This study was conducted at three different Fisheries Cooperatives and their fishing ports in the central district of Giresun between November 2023 and April 2024. Face-to-face interviews were conducted with 32 fishermen, members of the cooperatives at the fishing ports of the Giresun Fishery Cooperative, Üçkayalar Fishery Cooperative, and Aksu Neighbourhood Fishery Cooperative. The fisheries in the region, the socio-demographic characteristics of the fishermen, the current status of the cooperative, and their problems were identified on-site.

RESULTS

Fish auction is not held in the cooperatives studied. The catch fish is sold early in the morning to retailers at the fishing port. In addition, fish are sold to buyers from other provinces, especially Samsun. There is also a fish market in central Giresun, built by the Municipality and allocated the fishmongers. During anchovy season, fish are transport throughout Türkiye, but mostly to Ankara and Istanbul.

Giresun Fishery Cooperative

The oldest cooperative in Giresun province, the Giresun Fisheries Cooperative, was established in 1955. The fishing port, operated by the cooperative, has 150 registered members. Fishing boats in the port ranged in length from 4 to 48 m. The most commonly used fishing gear includes purse seines, gill / trammel nets, and fishing lines for fish such as horse mackerel, anchovy, red mullet, garfish, and bluefish.

Üçkayalar Fishery Cooperative

It is located in central Giresun. Also known as Gemilerçekeği, this place has the second largest fishing port and boatyard in Giresun. It was built in 1974. The cooperative was established in 2015. The main breakwater is 270 m long. The infrastructure includes electricity and fresh water connections, while the superstructure includes an administrative building and restrooms. It is a boatyard with a high density of boats. There are 130 registered boats using the boatyard. The lengths of the boats ranged from 4 to 10 m. Fishing is done with gill / trammel nets and fishing lines. Depending on the season, the catch is mostly horse mackerel, whiting, red mullet, bluefish, and garfish.

Aksu Neighbourhood Fishery Cooperative

The Aksu fishing port and boatyard are located east of Giresun city center. The cooperative was established in 2014. The main breakwater is 127 m long. There are no infrastructure or superstructure facilities. The length of vessels varies between 4 and 7 m. Fishing activities use gill / trammel nets, and the catch is generally horse mackerel, garfish, bonito, whiting, and bluefish.

Socio-Demographic Characteristics of Fishermen

During the interviews with the fishermen, questions were asked about their personal characteristics, level of education, fishing experience, and why reasons for choosing fishing (Table 1).

Table 1. Some socio-demographic characteristics of fishermen in Giresun (min-max values in the right parenthesis).

Age of fisherman (mean $\pm$ SD)	56.6 $\pm$ 10.6 (29–80)
Fishing experience (year, mean $\pm$ SD)	30.4 $\pm$ 13.3 (4–60)
Number of days spent fishing (year, mean $\pm$ SD)	128.3 $\pm$ 55.2 (4–60)
Number of crew on board (mean $\pm$ SD)	2.1 $\pm$ 5.5 (0–25)
Those all income comes from fishing (%)	31.2
Married (%)	87.5
Going fishing with his wife (%)	18.7
Wants their child to become a fisherman (%)	25.0
Reason for choosing fishing (%)	
-Sea passion	53.0
-Father's profession	35.0
-Subsistence	9.0
-Other	3.0
Has social security (%)	
-SSK	62.5
-Bağ-Kur	21.9
-Emekli Sandığı	15.6
Crew payment method (%)	
-Share	44.4
-Per diem	11.2
-Other	44.4
Marketing type (%)	
-Middleman	68.8
-Self	15.6
-Retailer	3.1
-Wholesale market	3.1
-Other	9.4
Income satisfaction (%)	
-Very good	9.4
-Good	15.6
-Average	21.9
-Poor	53.1
-Other	3.0

When we look at how the fishermen market their products, we see that, due to the lack of a fish whole sale market in the province, they largely sell their products to middleman. Some of their products are sold at the fish market built by the Giresun Municipality, while the rest is sent to other provinces.

When looking at the educational background of the fishermen, 60% have completed elementary school, 34% have completed high school, and 6% have completed college education.

Considering the fishermen's professional experience, 34.4% have less than 20 years, 21.9% have 21-30 years, and 28.2% have 31-40 years.

When we asked fishermen, "Do you make your living solely from fishing?" Because the region is predominantly populated by amateur fishing vessels, we found a large proportion of boat owners with diverse income sources. It appears that 69% of boat owners also earn money from non-fishing sources (55% are retired, while the remainder are workers, tradesman, teachers, and farmers).

A significant portion of fishermen are amateur fishermen and own small boats, so their sea passion (53%) is the primary reason for choosing fishing. 35% continue their father's profession.

When working hours are examined, it is seen that 59.4% of fishermen work between 4 and 6 hours.

Fishermen's Opinions and Problems About the Cooperative

In this section, fishermen were asked about their opinions about cooperatives, whether they had any problems with other fishermen, and whether they had any problems with the adequacy of the fishing ports they were in.

When fishermen were asked about their reasons for becoming members of the cooperative, they stated that their reasons for becoming members were largely to secure a place in the port (43.8%) and to benefit from bureaucratic conveniences (34.4%).

When we asked the fishermen, "Do you think cooperatives are successful?", most of the fishermen (63%) think that cooperatives are unsuccessful.

We asked the fishermen, "Would fish be sold at a lower price if the cooperative didn't exist?" All of the fishermen stated that the cooperative had no impact on fish prices.

Sixty-three percent of fishermen report that their fishing ports are inadequate.

We asked the small-scale fishermen if they had any problems with large-scale fishermen, and 56% said they did. These problems generally arise from competition for fishing in the same area. Small-scale fishermen say large-scale fishermen are overfishing and decreasing fish stocks. As a solution, they suggested that fish-finding devices like sonar and echo-sounders should be avoided and that fisheries authorities should implement stricter inspections.

When we asked fishermen, "Do you have any problems with dolphins and marine mammals?" 56% of them said yes. According to them, dolphins (65%) are the most problematic species. 35% of fishermen reported having problems with both dolphins and rays, while 17% reported having problems with both dolphins and rays, plus sharks.

DISCUSSIONS

This study conducted interviews with fishermen in three different cooperatives located in the central district of Giresun to determine some of the socio-demographic characteristics of the fishermen in the region and their opinions about the cooperatives. The majority of the fisheries in Giresun are small-scale and recreational fishermen. The most important target species in the region are horse mackerel, whiting, horse-mackerel, red mullet, garfish, bonito, bluefish, and anchovy. Sea snail (*Rapana venosa*) fishing is also very common. Fishermen generally use gillnets, beam-trawls, and various hand lines.

Coastal fishermen sell their fish through middlemen in fishing ports. Income from fish sales is received weekly (Mutlu et al., 2018).

All three cooperatives in the city center face significant problems. The fishing ports are inadequate and poorly maintained, the cooperatives' impact on fisheries is weak, they lack sustainable fishing initiatives, auctions are not even held, and they lack cold storage facilities. Similar problems have been confirmed by Erdoğan Sağlam and Çalık (2016b). Furthermore, almost all cooperatives report insufficient dues and rental income, leading to financial difficulties due to their inability to secure a source of income (Erdoğan Sağlam and Çalık, 2016b). Furthermore, it has been reported that none of the coastal facilities have pre-cooling storage, ice production facilities, or retail outlets (Tokmak Kırkses and Samsun, 2020).

This study suggests that the primary reason fishermen join cooperatives is to secure or retain their port space. A significant portion of the region's fishermen are amateur fishermen. They engage in this work either because they enjoy the sea or as a side hustle. Consequently, only a small portion of fishermen earn their entire living from fishing.

Most fishermen work 4-6 hours a day. Because there is no wholesale fish market in the province, they sell their products through middlemen or on their own. Most fishermen fishing during 100-200 days a year. The majority of fishermen are between 51 and 61 years old. Most fishermen are dissatisfied with their income. Despite this, while they have no intention of quitting fishing, they do not want their children to take up this profession.

Fishermen in Aksu fishing port are disturbed by the fact that the Giresun Municipality's zoning plan to remove the garbage dump next to the port includes their own port borders, and they say the newly built port poses a risk of flooding in adverse winds.

As a result of interviews conducted with fishermen in the region, it was determined that they have many problems. These are:

- Fishermen state that dolphins and rays pose a significant threat to them, tearing apart their nets and fishing lines, and that action must be taken to resolve this problem.

- Fishermen, especially in Kumyalı port, stated that the port is insufficient and small for boats and that it needs to be enlarged.

- Small-scale fishermen claim that large-scale fishermen are depleting the fish stocks in the region and that they are not adequately monitored. They want their use of fish-finder devices such as sonar and echo-saunders to be banned as a solution to this.

- Fishermen also complain that the facilities in the province are far behind those in the surrounding provinces and that there is no wholesale fish market.

-They state that garbage is still being thrown into the seaside garbage area and that this is polluting the sea.

In conclusion, it is expected that the necessary regulations, controls and inspections will be made in order to ensure the sustainability of small-scale fishing, especially in the region with fishing grounds suitable for fishing. For the development of the region's fisheries, cooperatives must be more effective and address their shortcomings. Establishing cold storage and holding auctions are also expected within the cooperatives. Furthermore, cooperatives' commitment to providing solutions to fishermen's problems and training in responsible fishing will significantly contribute to the development of the region's fisheries. Support can be obtained from the relevant ministries and universities in this regard.

Giresun definitely needs a wholesale fish market for its fishing industry to thrive.

Establishing a market would help fishermen access better marketing opportunities.

One of the fishermen's greatest expectations is for the fisheries management authority and the academicians to come together and find a solution to overcome the problems with species such as dolphins, sharks and rays.

Giresun Municipality should reconsider the development plan it will create in place of the garbage dump, taking into account the opinions and suggestions of the fishermen. Furthermore, garbage is still being dumped on the seashore, it should stop this in order to protect our seas and prevent environmental pollution.

ACKNOWLEDGEMENTS

This study is part of Ç. Çaykara's undergraduate thesis, supervised by O. Akyol. The authors would like to thank the heads of the Giresun Central Fishery Cooperatives, studied and the fishermen for their assistance.

ABSTRACT

Green vegetables contain various phytochemicals in suitable amounts, which are very helpful in preventing and fighting numerous diseases. They also have different types of vitamins and minerals for the effective functioning of the body system. Spinach is a leafy green flowering plant with edible leaves. The bioactive components and phytochemicals, such as flavonoids, polyphenols, carotenoids, and ascorbic acid present in the spinach (*Spinacia oleracea* L.) leaves, are responsible for their nutritional and medicinal properties. The study analyzed the bioactive compounds and phytochemicals present in spinach leaves. Phytochemicals in the spinach, including saponins, steroids, tannins, glycosides, flavonoids, phenols, phlorotannin, and ascorbic acids, were determined and screened according to the standard method using extracts from different solvents like water, ethanol and ethyl acetate. The leaf samples were collected, dried, and ground for extraction. The solvents, water, ethanol and ethyl acetate used for the extracts were incubated for 72 hours, then filtered and centrifuged. The centrifuged extracts were subjected to Gas Chromatography-Mass Spectroscopy (GC-MS) for further analysis of the bioactive compounds present. This analysis was achieved on a GC-MS Shimadzu GC-MSQP2010 Plus system equipped with an RTX-5 M.S. capillary column (0.25 mm x 30 m x 0.25 lm). The result established from the GC-MS analysis of the ethyl acetate extract and the ethanol extract of the spinach leaves was identified from 25 compounds in the chromatogram of each extract. The active compounds' names, compound structures, and molecular weights in the ethyl acetate and ethanol extracts were identified. This GC-MS spectrum proved the similarity percentage of these components as compared to the Wiley online library (WILEY8.LIB), which was the library source. This phytochemical composition's medicinal and nutritional value makes the plant highly essential for good health. However, these plant phytoconstituents have not been lost due to cooking. As a result of these positive effects seen in spinach, it is a green vegetable consumed everywhere in the world.

Keywords: Bioactive compounds, Gas Chromatography-Mass Spectroscopy, Phytochemicals, Spinach

INTRODUCTION

Agriculture is a major sustainable aspect that has immensely contributed to TRNC in terms of production, and commercial revenue. Cyprus is a semiarid island with insufficient rainfall. Out of about 329,890 hectares in northern Cyprus, 56% that is equivalent to 187,068 hectares is adequate for agricultural practices. The climatic conditions and to some extent shortage of water have been the major constraint. However, irrigation of lands is supposedly done for the growing of fruits and vegetables of different varieties. From 1985 to 2001, the land for Agricultural purpose has decreased by 6% and this was as a result of the urban development that has occurred over time (Agricultural Statistics, 2001). The farmers who grow fruits and vegetables have extensively adopted the consistent use of the modern irrigation systems with the most appropriate method of irrigation (Metochis and Eliades, 2002).

In Africa, western region especially and using Nigeria as a case study, Agriculture is still and will continue to stand as the most important sector that boost the economy of Nigerian. Not less than 65% of Nigerian population in general is evaluated to survive on agricultural products for adequate living, while 35% of the Gross Domestic Product are accompanied with agricultural contribution through the sector of modern agriculture. (FAO, 2006). Agriculture right from time immemorial has pose relevance in the development of Nigeria especially in the areas of economy and commerce. The merits of this has assisted in the availability of food for the vast population, employment for more than half of the entire population with the conversion of raw material for the earnings foreign exchange in the fast growing sector of industry (Adeboye, 1996).

Spinach (*Spinacia oleracea L.*) is a leafy and at the same time highly nutritious vegetable, which is adequately rich in nutrients and phytochemicals. Vitamins A (from β -carotene), C and K are the micronutrients that are present in spinach, with common minerals like calcium, iron and potassium. The phytochemicals present includes carotenoids, flavonoids, steroids, phlobatannins, saponins and phenolic compounds just to mention but a few of them (Bergquist, 2006). Various researchers have worked on identifying the bioactive compounds that are present not just in vegetables but also in fruits when considering the pre-harvest and postharvest factors.

One of the main reasons why the consumption of spinach is annually increasing is because people are now being conscious and more sensitive with their health than before and spinach which has always remains as one of the healthy vegetables rich in most of these essential nutrients needed for a healthy living. The vegetable is easy to grow with a short life span, which makes it possible for the vegetable to be grown all through the year.

The top five countries in the world that grow spinach include China, which is leading with the production of 27,540,167 tons per year. This is followed by the United States of America with a total production of 435,721 tons annually and followed by Turkey with a production of 229,793 tons. While Japan is the fourth with a production of 226,865 tons and Kenya the fifth and leading in Africa with an annual production of 178,707 tons annually. Nevertheless, Cyprus id quite rich in wild spinach.

Thus, the intention of this research is to investigate the different bioactive compounds and identify the phytochemicals present in the spinach leaves which could have a great impact on our nutrition and health benefits.

MATERIAL AND METHOD

The Bloomsdale variety leaves belong to the savoy species, which is the most popularly grown in Cyprus usually 30cm long and 15cm broad on the average, was selected and collected with plastic zip lock bags from a vegetable farm in northern Cyprus and taken to the laboratory. The spinach leaves were washed four times with water from the tap; this is to remove any debris from the leaves. This is then rinsed with distilled water and leave to be well dried to be suitable for extraction (Olasupo et al., 2018, Tiwari et al., 2005).

The qualitative studies of the bioactive compounds from plant materials depends mostly on the selection of the proper extraction method (Smith, 2003, Sasidharan et al., 2011). This extraction is the initial step taken in any medicinal or nutritional study of plants because it has significance on the result of the research. Sample preparation techniques are also known as the extraction methods.

The collected samples that are already well dried through the use of oven for 24 hours at 100 degree celcius were grinded to powder form. 5 grams of this powdered sample were then soaked in centrifuge bottles with 50 ml of water, ethanol, and ethyl acetate separately. The whole mixture was then incubated at 4°C for 72 hours. Immediately after this incubation period, the mixtures were carefully filtered with the use of the filter paper and centrifuged at 6,000 rpm at 4°C for a period of 60 minutes. The extracts were then concentrated to dryness in a rotary evaporator (IKA-RV 10 Control) at and were stored at 4°C for further use (Romanik et al., 2007, Moldoveanus and David 2015, Roshanak et al., 2016).

Phytochemical analysis of the test samples were carried out according to standard methods (Trease and Evans, 1989; Harborne, 1998) on test for;

1. Saponin

5ml of each of the plant extracts were added to 20ml of distilled water in a test tube. They were vigorously shaken and then mixed with 3 drops of olive oil. A stable persistent froth forms an emulsion. (Ejikeme et al., 2014).

2. Taninns

1 ml of each extract were boiled in 20 ml of water in a test and then filtered. A few drops of 0.1% ferric chloride were added and once green or a blue-black coloration is observed, it confirms the presence of tannin (Alhakmani et al., 2013).

3. Phenol

5 ml of the extract will be pipetted into a 30 ml test tube, then 10 ml of distilled water will be added. 2 ml of ammonium hydroxide solution and 5 ml of concentrated amyl alcohol will also be added and left to react for 30 min. Development of bluish green colour is a positive presence of phenol. (Alhakmani et al., 2013).

4. Flavonoids

3 ml of 1% Aluminium chloride solution was carefully added to 5 ml of each extract. A persistent yellow coloration appeared, indicating the presence of flavonoids. 5 ml of dilute ammonia solution was further added to the above mixture followed by the addition of concentrated H₂ SO₄. The yellow coloration disappeared. The yellow coloration which disappeared indicates a positive test for flavonoids (Chang et al., 2002),

5. Glycosides

5 ml of each extract was treated with 2 ml of glacial acetic acid containing one drop of ferric chloride solution and underplayed with 1 ml of concentrated sulphuric acid. A brown ring at the interface indicates a deoxysugar characteristic of cardenolides which confirms a positive presence of cardenolides. A violet-green ring appearing

below the brown ring, in the acetic acid layer, indicates that glycoside is present (Rangari 2002, Roshanak et al., 2016).

6. Steroids,

2 ml of acetic anhydride were added to 2 ml extract of each sample followed by careful addition of 2 ml H₂ SO₄. The color will change from violet to blue or green which confirms the presence of steroids (Rangari 2002).

7. Terpenoids (salkowski test),

5 ml of each extract were mixed with 2 ml of chloroform, and followed by a 3 ml concentrated H₂ SO₄ carefully added to form a layer. A reddish brown coloration of the interface was formed showing the positive presence of terpenoids (Rangari 2002).

8. Phlobatannins

2 ml of extract of each plant samples was boiled with 1% aqueous hydrochloric acid and a red precipitate showed the presence of phlobatannins (Rangari 2002, Roshanak et al., 2016).

RESULTS AND DISCUSSION

The results of the phytochemical test carried out on each of the extracts were recorded as shown in Table 1. This preliminary screening on each of the extracts show significant quantity of the phytochemical constituents, revealing the presence of saponins, flavonoids, terpenes, phenols, tannins, alkaloids, phlobatanin, glycoside and steroids. However, the phytochemical constituents in the various part of the spinach plant vary as well (Uraku 2016, Altemimi et al., 2017).

This present investigation revealed that the aqueous extract of spinach shows abundant presence of terpenes, and flavonoids, with moderate presence of saponins and less presence of phlobatanin and cardenolides but steroids, glycosides, phenol, glycosides and tannins are absent in the aqueous extract.

For the ethanol extract, tannins and glycosides are moderately present, while steroids and phenol are less present but saponins, flavonoids, terpenes, cardenolides and phlobatanin are absent.

The investigation also revealed much abundant presence of saponins and cardenolides in ethyl acetate extract, with a moderate presence of phenol and less presence of tannins and flavonoids, but showed absence of phlobatanin, terpenes, steroids, glycosides.

Phytochemicals are non-nutritive plant chemicals that have disease preventive properties (Kumar et al., 2009). Different phytochemicals have been found to possess a wide range of activities. The phytochemicals are known to have antimicrobial activity (Ebana, 1995).

Different studies have proved that spinach has a high nutritional value (Maeda et al., 2005). Many researchers also reported that, glycosides play very crucial role in reducing blood pressure. They could also be used in treating heart failure (Nyarko AA & Addy M E 1990).

The spinach leaf extract with their phytoconstituents are reportedly known for anti-inflammatory, antidiarrheal, antimicrobial, antioxidant and insecticidal activities (Chouhan HA & Singh SK, 2011). Steroids are very much important in pharmacy because of their relationship with compounds like sex hormones and can be used for drug production (Okwu DE 2007).

Tannin and flavonoid are thought to be responsible for antidiarrheal activity (Enzo, 2007). Usman and Osuji reported that tannin has been widely used topically to sprains, bruises and superficial wounds as such. Similarly, Elmarie and Johan reported tannin to have antibacterial. Phytochemicals such as terpenoid, flavonoid, tannin, steroid, and alkaloid have antiinflammatory effects (Liu, 2003) Flavanoids show anti allergic, anti-inflammatory, anti-microbial and anti-cancer activity (Yamato and Gayor, 2002).

The result established from the GC-MS analysis that was carried out from the ethyl acetate extract and the ethanol extract of the spinach leaves were identified from 25 compounds from the chromatogram on each of the extract, and this is well summarized in Table 2 and Table 3 respectively. The active compounds name, compound structures and molecular weight in the ethyl acetate and ethanol extract were identified. This GC-MS spectrum confirmed the similarity percentage of these various components when compared to the Wiley online library (WILEY8.LIB) which was the library source.

CONCLUSIONS

For this present research, the commonly consumed spinach variety in north Cyprus, the Bloomsdale variety leaves which belongs to the savoy species contains adequate quantity of phytochemicals that are helpful in the prevention deadly diseases to mankind.

The GC-MS analysis of these phytochemicals, and the studies of the bio active compounds, indicate positive results for ethyl acetate, ethanol and aqueous extract of the spinach leaves. The phytochemical screening also shows the presence of saponins, terpenoids, phlobatannins, flavonoids, taninns, glycosides, steroids and phenols.

This current research has also explained that the spinach is one of the vegetables in north Cyprus that is consumed on daily basis, not only because it is cheap to get, but it's a green vegetable that is very rich in most of the phytochemicals and bio active compounds present in leafy green vegetables. The medicinal and nutritional values which are of these phytochemical composition, makes the plant to be highly essential for good health and also with its properties that can be useful in combating health challenges. However, there have not been losses of these plant phytoconstituents, as a result of cooking, except for vitamins and minerals. As a result of these positive effects seen in spinach, it is a green vegetable that is consumed everywhere in the world. It is best consumed cooked, except for a very few places where little amounts are added to meals like salad and eaten raw.

ABSTRACT

Wheat is crucial in providing food and nutritional security, but rapidly increasing soil and water salinity severely threatens its production worldwide. Salinity has a direct impact on soil productivity and limits global yield potential. It also deleteriously impacts wheat growth and development, reducing grain production and quality. Wheat plants use a variety of physiological, biochemical, and molecular mechanisms to adapt to salt stress at the cell, tissue, and whole plant levels to optimize growth and yield while mitigating the harmful impacts of the saline environment. An experiment was conducted at the Institute of Graduate Studies and Research Department of Plant Sciences and Technologies, Cyprus International University, to examine the effect of salinity stress. In the present experiment, wheat varieties V1, V2, and V3 were tested under EC control, 7.5 dS m⁻¹, 10 dS m⁻¹, and 12 dS m⁻¹ following a completely randomized design (CRD) with factorial arrangement. The findings revealed that wheat growth and yield characteristics decreased dramatically as saline levels increased. Among V1, V2, and V3, the highest reduction in plant height, SFW, SDW, RFW, RDW, number of tillers, spike length, and grain yield were noted in V3 when treated with 12 dS m⁻¹. Furthermore, V1 performed best as compared to all other varieties.

Keywords: Salinity, Wheat, Antioxidants, Growth, Yield

INTRODUCTION

Earth contains different type of salts. Major portion of earth is covered with water and there is approximately 3% NaCl in that water (Breiman & Graur, 1995; Royo & Abió, 2003; Hajhashemi et al., 2009). However, the total area of the earth that becomes salt-affected is not precisely known according to an estimate about 930Mha of the earth is salt affected and distributed throughout the world (Robin et al., 2016).

Soil salinization is a severe environmental issue worldwide, primarily affecting soil and crop productivity in arid and semi-arid areas due to high temperature and low rainfall (de Sa et al., 2021). Over the previous 45 years, the salt-affected soil area has expanded by 77 million ha, becoming a severe hazard, particularly for irrigated agriculture (Munns, 2002). Salt-affected soils cover an area of around 1060.1 Mha in the world and their area is gradually increasing due to the influence of climate change; soil salinity tends to increase with increase in sea level intrusion and temperature, decrease in precipitation and improper irrigation management (Eswar et al., 2021). It is a major challenge to modern agriculture, impeding and impairing crop

growth and development, especially in coastal areas and most arid regions of the world (Zaman et al., 2018).

It has been reported that salt stress has affected 20% of agricultural land. However, this problem is enhancing gradually owing to anthropogenic activities as well as different changes within climatic conditions (Arora, 2019). Due to salinity stress according to an estimate 50% reduction in crop production has been recorded (Acquaah, 2007). While, there is need to increase food supply up to 70% by 2050 in order to fulfill the demands of continuously increasing population (FAO, 2009).

Salinity has a detrimental effect on the chemical, physical, and biological properties of soil because of the high concentration of salts of basic cations in the soil and yield because of osmotic and ionic stress besides inhibit seed germination, structure and functions of the photosynthetic machinery, resulting in less economical agricultural production and rural poverty (Jahan et al., 2020). However, soil parent material, anthropogenic activities, and arid and semiarid climatic conditions contribute to unfavorable soil conditions like low rainfall which limits leaching of salts, causing accumulation of Ca-minerals that strongly changing soil organic matter turnover and nutrient recycling resultantly crop production decrease (Acquaah, 2007; FAO, 2009.; Wiese, 1977). Improving future agricultural management demands that soil salinity should be taken into consideration (Ennaji et al., 2018).

Variation in climatic conditions, increase in temperature and low rainfall are the red signals indicating that there is need to bring salt affected soils under cultivation to fulfil day by day increasing demands of food (Akhiyarova et al., 2005; Akbari et al., 2007). So, it is important to examine the maximum adverse outcome of excessive salts in the crop growth along with isolate salt tolerant varieties for maximum yield (Huang et al., 2010; Turan et al., 2009; Çelik & Atak 2012).

The growth and production of wheat is reducing throughout the world due to several factors such a decrease in agricultural land, environmental variations, extensive application of chemical fertilizer and less application of organic fertilizers (Masuda, 2016). Many sections of the world are vulnerable to stressors such as salt, which has a harmful effect on plant growth and yield production (Hasanuzzaman et al., 2014a; Hasanuzzaman et al., 2014b; Shabala & Munns 2012). Around 20% of agricultural fields are saline, and because of the significant issue of global warming, increasingly cultivable lands are becoming salty. Because many stressors, including salinity, result in yield decreases of up to 50% (Munns and Tester, 2008; Munns et al., 2019), while it is important to enhance food production up to 70% by 2050 (FAO, 2009).

Salinity effect plant growth and development via various mechanisms, among them two most important are discussed here (1) the harmful impacts of sodium (Na^+) and chloride (Cl^-) ions, and (2) the osmotic capacity influencing plant physiology. Though, plants can tolerate salinity stress (Rahman et al., 2016; Afzal et al., 2005). Based on their ability to tolerate salinity plants can be tolerant, moderately tolerant, and sensitive. Different researchers classified wheat as a tolerant crop. However, wheat can tolerate salinization to some extent, but its production decrease under heigh level of salinity stress (Poustini & Siosemardeh, 2004; James et al., 2006). Plant synthesis energy via photosynthesis, this energy is utilized in maintenance, plant growth, and to survive under several types of abiotic and biotic hassles during growth stages (Miransari & Smith, 2019).

Under salinity stress plants activate various type of signaling pathways. Salinity stress give rise to artificial drought conditions under such conditions water is present in high amount but due to high concentration of soluble salts plants are unable to absorb water. In response to salinity coupled with drought stress production of reactive oxygen species (ROS) increases. These ROS negatively effects plant metabolism and reduces its ability to cope under stress conditions (Miransari & Smith, 2019).

Keeping in view the above-mentioned adverse impact of salinity on crop yield. This trail aims to define the influence of salt stress on three wheat varieties. Our objectives are;

- I. To examine the impact of soil salinity on biochemical parameters of wheat under different salinity levels.
- II. To determine salinity level at which maximum yield can be obtained under climatic conditions of Nicosia.

MATERIAL AND METHOD

Experiment

A pot experiment was performed at Institute of Graduate Studies and Research department of Plant sciences and technologies, Cyprus International University. The wheat varieties were grown in pots containing 20 kg by weight. Soil for the experiment was taken from the farm. The soil was air-dried and sieved through a 2 mm sieve. Before the start of experiment soil properties, such as E_Ce, pHs, saturation percentage, SAR, texture and NPK was determined following standard methods.

Development of salinity

After preliminary analysis, four different levels of soil salinity i.e. control (C), S₁ = 7.5, S₂ = 10 and S₃ = 12 dSm⁻¹ was prepared by using a calculated amount of NaCl, Na₂SO₄, CaCl₂, CaSO₄ salts and mixing along with the soil in a mixing tub to achieve maximum homogeneity so that the required salinity levels can be establish in soil samples (Muhammed and Ghafoor, 1992).

Pot filling, fertilization, seed sowing and irrigation

Each pot was filled with 10 kg soil, after developing the required salinity levels, and seeds of wheat shall be sown in each pot. As per requirement thinning was carried out 45 days after planting, leaving 4 plants in each pot. The recommended dose of NPK for wheat was be applied before sowing according to planned treatments. Each pot was treated as per the following treatments.

Treatments layout

Four salinity levels and wheat varieties were used to determine effect of salinity stress on wheat growth, and yield parameters. A completely randomized design with factorial arrangements of 12 treatments each with 3 replications was used.

Varieties = V₁, V₂, V₃ (Perre, Cumhuriyet 75, Gori)

Salinity levels = C, S₁, S₂, S₃

Number of pots = V*S*Replications = 3*4*3 = 36

Plant parameters

Following parameters of crop will be measured after harvesting the wheat crop.

Shoot length (cm)

To measure the length of wheat shoot, meter rod will be used. Later, mean of shoot length will be calculated.

Root length (cm)

Plants root length of all samples will be estimated with meter rod. After those values of mean shall be determined.

Shoot fresh weight (g)

Fresh weight of shoot will be measured using electronic weighing balance.

Shoot dry weight (g)

Weight of dry shoot will be measured after putting shoot samples in an oven at $65 \pm 5^\circ\text{C}$ temperature for 24 hours.

Number of tillers

At maturity after randomly selecting one plant per pot total numbers of tillers of that plant were counted and mean value for number of tillers per plant were calculated.

Spike length (cm)

Spike lengths of three randomly chosen plants were measured by using meter rod. For measuring spike length, length from start point of spike to the upper tip of the spike was noted and its mean length was calculated.

Grains per spike

After harvesting the spikes were manually threshed and separately counted the number of grains per spike and then average was calculated.

100 grain weight

Grains were counted by using seed counter, weighted on an electrical balance at the time of harvesting from each replication. At the end mean value for 100 grain weight was estimated.

Grain yield

Grains of each pot were manually harvested, and their weight was recorded by weighing balance.

Straw yield

Plants of each pot were harvested manually, tied into bundled and sun dried for a week. By means of digital balance total biomass of sun-dried samples were recorded.

Harvest index

Harvest index % (HI%) can be calculated by the given formula.

$$HI(\%) = \frac{\text{Grain Yield(g)}}{\text{Straw yield(g)}} \times 100$$

Biochemical parameters

Total chlorophyll content

The chlorophyll content of fully mature wheat leaf will be determined using Chlorophyll meter (SPAD-value) at three different points (Welburn, 1994) and then averaged.

RESULTS AND DISCUSSION

Shoot length (cm)

Salinity stress adversely effects different physiological along with biochemical developments of plant in addition to reduces its growth along with improvement. ANOVA table 4.1.1 shows the impact of soil salinity on shoot length of three varieties of wheat i.e., V1, V2, and V3. ANOVA table showed that the interaction between salinity stress and plant height is highly significant in all wheat varieties. Furthermore, it can be depicted from the Fig 4.1.1 that with increase in salinity considerable reduction in shoot length was observed. However, highest shoot length (115cm) was observed in V1 under controlled conditions. While lowest shoot length i.e., was observed in V3 treated with 12 dS m⁻¹ salt stress.

Moreover, the results of this research demonstrated that salinity stress reduced shoot length by 21.7%, 39%, and 52% in V1 treated with SL1, SL2, and SL3 respectively as compared to control. In V2 a reduction in shoot length was also observed. The results showed 25%, 40%, and 63% reduction in shoot length as associated to control. Lastly the outcomes of this study indicated a reduction of 29%, 44.8%, and 65.4% in shoot length in pots treated with 7.5 dSm⁻¹, 10 dS m⁻¹, and 12 dS m⁻¹ correspondingly. According to our findings V1 performed best as linked to V2 and V3. The outcomes of our research demonstrated that with increasing level of salinity plant height was reduced. Our conclusions are also justified by Nazeer et al. (2021) who stated that salinity negatively effects growth of wheat by decrease in tissue water contents. Elevated absorption of salts in soil solution induces osmotic stress. Osmotic influence reduces activity of meristematic cells in shoot axis thereby cell elongation and consequently plant height (Qiong et al., 2016).

Siddiqui et al. (2021); EL Sabagh et al. (2021) also reported the adverse impact of salinity on plant height. Salinity stress increases the concentration of Na and Cl ions that leads to ionic stress which adversely effects biochemical and metabolic processes in older leaves that resultantly causes decrease in leaf expansion and photosynthetic capacity. Leaves are the production houses of plant and because of impaired functioning of leaves the ability of plant to generate energy decreases that ultimately decreases plant height (Fathalla and El-Mageed, 2020). In another research Kalhor et al. (2016) reported reduction in plant height, spike size, quantity of spikelets spike⁻¹, 1000 grain mass, as well as yield. However, salinity level of 10 dS m⁻¹ has more harmful effect as associated to 2.16, 4.0, 6.0, 8.0 dS m⁻¹. The impact of soil salinity on shoot arid weight, and wheat yield was observed by Elgharably et al. (2010). In this experiment wheat response to EC level 2.2, 6.7, 9.2 and 11.8 dS m⁻¹ and four different

concentrations of N and P was recorded. The results showed that EC level 11.8 dS m^{-1} considerably decreased the shoot, and grain yield but application of N and P increased the growth and yield related components.

Root length (cm)

Salinity stress adversely effects different biological as well as bio-chemical methods of plant and reduces its growth and development. ANOVA table 4.2.1 shows the impact of soil salinity on root length of three varieties of wheat i.e., V1, V2, and V3. ANOVA table showed that the interaction between salinity stress and plant height is highly significant in all wheat varieties. Furthermore, it can be depicted from the Fig 4.2.1 that with increase in salinity significant an increase in root length was observed. However, highest root length (40 cm) was observed in V1 treated with 12 dS m^{-1} salinity stress. While lowest root length i.e., 19 was observed in V2 under controlled conditions.

In addition, the findings of this study showed that salinity stress increased root length by 29%, 54%, and 62% in V1 treated with SL1, SL2, and SL3 respectively as compared to control. In V2 an increase in root length was also observed. The results showed 29%, 46%, and 61% increase in root length as compared to control. Lastly the results of this study showed an increase of 22%, 60%, and 72% in root length in pots treated with 7.5 dS m^{-1} , 10 dS m^{-1} , and 12 dS m^{-1} correspondingly. According to our findings V1 performed best versus V2 and V3.

The outcomes of our study revealed that with increasing level of salinity plant height was reduced. Our outcomes are also justified by Nazeer et al. (2021) who described that salinity negatively effects growth of wheat by decrease in tissue water contents. High intensity of salts in soil mixture stimulates osmotic effect. Osmotic influence reduces activity of meristematic cells in shoot axis thereby cell elongation and consequently plant height (Qiong et al., 2016).

Siddiqui et al. (2021); EL Sabagh et al. (2021) also reported the adverse effect of salinity on plant height. Salinity stress increases the concentration of Na and Cl ions that leads to ionic stress which adversely effects biochemical and metabolic processes in older leaves that resultantly causes decrease in leaf expansion and photosynthetic capacity. Leaves are the production houses of plant and because of impaired functioning of leaves the ability of plant to generate energy decreases that ultimately decreases plant height (Fathalla and El-Mageed, 2020). In another research Kalhor et al. (2016) reported reduction in plant elevation, spike size, quantity of spikelets spike^{-1} , 1000 grain mass, along with yield. However, salinity level of 10 dS m^{-1} has additional unfavorable effect as associated to 2.16, 4.0, 6.0, 8.0 dS m^{-1} . The impact of soil salt on shoot dry weight, root dry weight and wheat yield was observed by Elgharably et al. (2010). In this experiment wheat response to EC level 2.2, 6.7, 9.2 and 11.8 dS m^{-1} and four different concentrations of N and P was recorded. The results showed that EC level 11.8 dS m^{-1} considerably decreased dry weight of shoot and root and also reduced grain yield, but application of N and P increased the yield related components. So, from the previous studies it can be concluded that salinity reduces root size.

Grains per spike

Salinity stress adversely effects different physiological and biochemical processes of plant and reduces their growth and development. ANOVA table 4.9.1 shows the impact of soil

salinity on grains per spike of three varieties of wheat i.e., V1, V2, and V3. ANOVA table showed that the interaction between salinity stress and plant height is highly significant in all wheat varieties. Furthermore, it can be depicted from the Fig 4.9.1 that with increase in salinity significant reduction in grains per spike was observed. However, a highest grain per spike (51) was observed in V1 under controlled conditions. While a lowest grain per spike i.e., 22 was observed in V2 treated with 12 dS m^{-1} salinity stress.

In addition, the findings of this research showed that salinity stress reduced grains per spike by 8%, 37%, and 45% in V1 treated with SL1, SL2, and SL3 respectively as compared to control. In V2 a reduction in grains per spike was also observed. The outcomes showed 10%, 22%, and 55% reduction in grains per spike as associated to control. Lastly the results of this study showed a reduction of 4%, 25%, and 44% in grains per spike in pots treated with 7.5 dS m^{-1} , 10 dS m^{-1} , and 12 dS m^{-1} correspondingly. According to our findings V1 performed best as assessed to V2 and V3. The findings of our research demonstrated that with increasing level of salinity plant height was reduced. Our outcomes are also justified by Nazeer et al. (2021) who stated that salinity negatively effects growth of wheat by decrease in tissue water contents. High-level absorption of salts in soil mixture causes osmotic stress. Osmotic impact reduces activity of meristematic cells in shoot axis thereby cell elongation and consequently plant height (Qiong et al., 2016).

Siddiqui et al. (2021); EL Sabagh et al. (2021) also stated the adverse effect of soil salinity on plant height. Salinity stress increases the concentration of Na^+ as well as Cl^- ions that leads to ionic stress which adversely effects biochemical and metabolic processes in older leaves that resultantly causes decrease in leaf expansion and photosynthetic capacity. Leaves are the production houses of plant and because of impaired functioning of leaves the ability of plant to generate energy decreases that ultimately decreases plant height (Fathalla and El-Mageed, 2020). In another research Kalhor et al. (2016) reported reduction in plant elevation, grains per spike, quantity of spikelets spike⁻¹, 1000 grain weight, as well as yield. Though, salinity level of 10 dS m^{-1} has additional unfavorable effect as linked to 2.16, 4.0, 6.0, 8.0 dS m^{-1} . The impact of salt on grains per spike, grains per spike and wheat yield was observed by Elgharably et al. (2010). In this experiment wheat response to EC level 2.2, 6.7, 9.2 and 11.8 dS m^{-1} and four different concentrations of N and P was recorded. The results showed that EC level 11.8 dS m^{-1} significantly reduced the shoot, grains per spike, and grain yield but application of N and P increased the yield related components. So, from the previous studies it can be concluded that salinity reduces grains per spike.

Grain Yield (g/pot)

Salinity stress adversely effects different physiological as well as biochemical processes of plant and reduces their growing along with development. ANOVA table 4.10.1 shows the impact of soil salinity on grain yield of three varieties of wheat i.e., V1, V2, and V3. ANOVA table showed that the interaction between salinity stress and plant height is highly significant in all wheat varieties. Furthermore, it can be depicted from the Fig 4.10.1 that with increase in salinity significant reduction in grain yield was observed. However, highest grain yield (38g) was observed in V1 under controlled conditions. While lowest grain yield i.e., 7g was observed in V3 treated with 12 dS m^{-1} salt stress. Additionally, the consequences of this investigation

indicated that salinity stress lowered grain yield by 19%, 25%, and 76% in V1 treated with SL1, SL2, and SL3 respectively as linked to control. In V2 a reduction in grain yield was also observed. The findings indicated 2.7%, 31%, and 76% reduction in grain yield as compared to control. Lastly the results of this study showed a reduction of 6%, 35%, and 78% in grain yield in pots treated with 7.5 dSm^{-1} , 10 dS m^{-1} , and 12 dS m^{-1} correspondingly. According to our findings V1 performed best as linked to V2 and V3.

The outcomes of our research demonstrated that with increasing level of salinity plant height was reduced. Our results are also explained by Nazeer et al. (2021) who described that salinity negatively effects growth of wheat by decrease in tissue water contents. High-level absorption of salts into soil solution stimulates osmotic stress. Osmotic impact reduces activity of meristematic cells in shoot axis thereby cell elongation and consequently plant height (Qiong et al., 2016). Siddiqui et al. (2021); EL Sabagh et al. (2021) also informed the unfavorable effect of soil salinity on plant height. Salinity stress increases the concentration of Na along with Cl ions that leads to ionic stress which adversely effects biochemical and metabolic processes in older leaves that resultantly causes decrease in leaf expansion and photosynthetic capacity. Leaves are the production houses of plant and because of impaired functioning of leaves the ability of plant to generate energy decreases that decreases plant height (Fathalla and El-Mageed, 2020). In another research Kalhor et al. (2016) reported reduction in plant height, grain yield, number of spikelets spike⁻¹, 1000 grain weight, and yield. However, salinity level of 10 dS m^{-1} has additional unfavorable effect as linked to 2.16, 4.0, 6.0, 8.0 dS m^{-1} . The effect of salinity on grain yield, grain yield and wheat yield were observed by Elgharably et al. (2010). In this experiment wheat response to EC level 2.2, 6.7, 9.2 and 11.8 dS m^{-1} and four different concentrations of N and P was recorded. The results showed that EC level 11.8 dS m^{-1} significantly reduced the shoot, grain yield, and grain yield but application of N and P increased the yield related components.

In addition, the findings of this experiment showed that salinity stress reduced grain yield by 19%, 24%, and 76%, in V1 treated with SL1, SL2, and SL3 respectively as compared to control. In V2 a reduction in grain yield was also observed. The results showed 3%, 33%, and 77 % reduction in grain yield as associated to control. Lastly the results of this study demonstrated a reduction of 20.5 %, 25 %, and 76.9 % in grain yield in pots treated with 7.5 dSm^{-1} , 10 dS m^{-1} , and 12 dS m^{-1} correspondingly. In accordance with our findings V1 performed best as compared to V2 and V3.

Figure 1. Effect of salinity on shoot length

Figure 2. Effect of salinity on root length

Figure 3. Effect of Salinity on grains per spike

Figure 4. Effect of Salinity on grain yield of wheat

CONCLUSIONS

Keeping under consideration the interactive effect of salinity levels and varieties best results of plant height, spike length, number of tillers, 1000 grain weight, along with grain yield were observed in V1 under control conditions. However, this experiment suggested that improving salt acceptance of wheat varieties can be an effective strategy to increase crop growth

and production under saline conditions. While using salt tolerant varieties and applying organic amendments along with salt tolerant microbes can be more effective.

ABSTRACT

Mushrooms are valuable natural sources of antioxidants due to their richness in phenolic compounds, polysaccharides, and other bioactive metabolites. Several species, such as *Ganoderma lucidum*, *Inonotus obliquus*, and *Trametes hirsuta* have exhibited remarkable antioxidant properties through radical scavenging, reducing power, and metal-chelating activities. These findings underscore the potential of mushrooms as functional food ingredients and natural alternatives in pharmaceutical formulations. Antioxidant mushrooms play a crucial role in reducing oxidative stress caused by free radicals, thereby protecting cellular components and contributing to the prevention of chronic diseases. Research on the biological activity of *Inonotus cuticularis* is still limited, but interest in its bioactivity and chemical composition has been increasing. In this study, *I. cuticularis*, which grows naturally in Türkiye and is traditionally consumed as tea, was extracted using solvents of increasing polarity (hexane, ethyl acetate, methanol, and water). The antioxidant activities of the extracts were evaluated using four standard assays: DPPH, ABTS, CUPRAC, and metal-chelating activity. Among the extracts, the water extract exhibited the strongest metal-chelating activity (IC₅₀: 63.25±0.56 µg/mL). Ethyl acetate and methanol extracts showed moderate CUPRAC (IC₅₀: 72.48±0.85 and 85.28±0.52 µg/mL) and ABTS (IC₅₀: 92.58±0.55 and 95.28±0.12 µg/mL) activities, while all extracts displayed weak DPPH activity (IC₅₀ > 200 µg/mL). These results suggest that *I. cuticularis* possesses moderate antioxidant potential, particularly in terms of metal chelation and reducing power. However, further research is needed to optimize its activity and identify its active constituents for pharmaceutical or nutraceutical applications.

Keywords: *Inonotus cuticularis*, antioxidant activities, DPPH, ABTS, CUPRAC, metal chelate

INTRODUCTION

Free radicals are a major cause of disease and aging. Antioxidants reduce these harmful effects. Natural products contribute to health with their antioxidant effects and are gaining importance in the field of functional food and nutraceuticals (Duru et al., 2019; Abdelshafy et al., 2022).

Mushrooms are valuable natural sources of healthy nutrition, owing to their low calorie content, essential fatty acids, proteins, vitamins, and minerals. Many mushroom species are widely collected and consumed as nutritious food across different regions of the world (Duru & Çayan, 2015; Park et al., 2024; Korkmaz et al., 2024). Mushrooms exhibit over a hundred medicinal effects, mainly including antioxidant, anticancer, antidiabetic, immune-modulating, cardioprotective, antiviral, antibacterial, anti-inflammatory, and hepatoprotective activities (Chen and Seviour, 2007; Yu et al., 2009; Zhang et al., 2011; Finimundy et al., 2013; Chun et al., 2021; Çayan et al., 2021; Kuş et al., 2025).

Inonotus cuticularis (Bull. ex Fr.) Karst. belongs to the Hymenochaetaceae family (Sesli et al., 2020). It grows on rotten wood of *Quercus* species and broad-leaved trees (Amoopour et al., 2016; Guo et al., 2020; Vemić et al., 2024). It has a natural distribution in Asia, Africa, China, France, Iran, Italy and Türkiye (Amoopour et al., 2016; Guo et al., 2020; Sesli et al., 2020). In this study, *Inonotus cuticularis*, which is naturally distributed in our country, consumed as tea and has commercial potential, was extracted with increasing polarity (hexane, ethyl acetate, methanol and water) and antioxidant activities of the extracts were investigated. Antioxidant activities of *I. cuticularis* extracts were investigated by different methods (DPPH free radical scavenging, ABTS cation radical scavenging, CUPRAC and metal chelate activities).

MATERIAL AND METHOD

1. Mushroom Material

Inonotus cuticularis specimens were collected from *Eucalyptus* and *Quercus* species in their natural habitat in Datça, Türkiye. The collected samples were taxonomically identified using the identification keys provided by Ghobad-Nejhad and Kotiranta (2008), Sharma et al. (2013), and the updated List of Fungi of Turkey (Sesli et al., 2020). A voucher specimen was deposited in the Natural Products Laboratory of Muğla Sıtkı Koçman University under the code ME2405. Macroscopic images of *I. cuticularis* are shown in Figure 1.

Figure 1. Macroscopic views of *I. cuticularis*

2. Mushroom Extract

A total of 800 grams of dried *I. cuticularis* material was subjected to solvent extraction at room temperature using a sequential method with increasing solvent polarity: hexane, ethyl acetate, methanol, and water. Each extraction was performed three times ($24 \text{ h} \times 3$). After filtration, solvents were evaporated under reduced pressure using a rotary evaporator. The masses and yields of each extract are listed in Table 1. Quantities and yields of *I. cuticularis* extracts

Mushroom	Extract	Code	Quantities	% Yields
<i>Inonotus cuticularis</i>	Hexane	ICH	1.92 g	% 0.24
	Ethyl acetate	ICE	11.65 g	% 1.46
	Methanol	ICM	7.35 g	% 0.92
	Water	ICS	5.60 g	%0.70

3. Antioxidant Activity

Four in vitro antioxidant assays were performed on all extracts of *I. cuticularis*:. These were:

- DPPH (2,2-diphenyl-1-picrylhydrazyl) radical scavenging activity,
- ABTS (2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid)) cation radical scavenging activity,
- CUPRAC (Cupric Ion Reducing Antioxidant Capacity) and
- Metal-chelating activity.

All analyses were conducted following the method described by Taş et al. (2021). Butylated hydroxyanisole (BHA), α -tocopherol, and ethylenediaminetetraacetic acid (EDTA) were used as reference standards. The antioxidant capacity of each extract was expressed as the concentration required to inhibit 50% of radical activity (IC_{50}), determined from inhibition percentage versus concentration ($\mu\text{g/mL}$) plots.

RESULTS AND DISCUSSION

The antioxidant activities of *Inonotus cuticularis* extracts (hexane, ethyl acetate, methanol, and water) were evaluated using DPPH, ABTS, CUPRAC, and metal-chelating assays. The results were compared to those of standard antioxidants (BHA, α -tocopherol, and EDTA), and the IC_{50} values were calculated for each assay (Table 2).

Table 2. Antioxidant Activity Results of *I. cuticularis* Extracts (p<0.05)

Extracts /	DPPH	ABTS	CUPRAC	Metal Chelate
Reference	IC ₅₀	IC ₅₀	A _{0.50}	IC ₅₀
	(µg/mL)	(µg/mL)	(µg/mL)	(µg/mL)
Hexane	>200	>200	>200	>200
Ethyl acetate	>200	92.58±0.55	72.48±0.85	>200
Methanol	>200	95.28±0.12	85.28±0.52	92.76±0.84
Water	>200	>200	>200	63.25±0.56
α-Tocopherol	38.20±0.50	34.50±0.55	60.45±0.37	-
BHA	19.50±0.40	12.70±0.10	25.40±0.22	-
EDTA	-	-	-	5.50±0.35

*Activity results expressed as mean ± standard deviation (SD) of 3 parallel tests (p<0.05)

The water extract of *I. cuticularis* exhibited the most significant metal-chelating activity (IC₅₀: 63.25 ± 0.56 µg/mL), whereas all extracts showed negligible DPPH radical scavenging activity (IC₅₀ > 200 µg/mL). Ethyl acetate and methanol extracts demonstrated moderate ABTS and CUPRAC activities, with the ethyl acetate extract slightly outperforming the methanol extract.

When compared with reference compounds, all *I. cuticularis* extracts exhibited lower antioxidant efficacy. BHA was found to be the most effective in DPPH and ABTS assays, while EDTA showed superior metal-chelating activity.

These results suggest that the antioxidant activity of *I. cuticularis* varies significantly depending on the solvent used for extraction. The differences in extract efficacy may be attributed to variations in the composition and solubility of bioactive compounds, such as phenolics and terpenoids.

The antioxidant potential of *I. cuticularis* has been evaluated in a limited number of studies. Li et al. (2011) reported strong inhibitory activity of *I. cuticularis* extract against mouse sarcoma (S180) and esophageal carcinoma (Esc) cell lines, although no specific bioactive compound was isolated. Dokhaharani-Chaharmiri et al. (2023) studied Iranian *I. cuticularis* and *I. levis* extracts and reported DPPH IC₅₀ values ranging from 144.98 to 333.52 µg/mL, and ABTS values between 128.06 and 290.23 µg/mL. Their findings indicated that ethyl acetate and acetone extracts showed the highest antioxidant activity. Similarly, Maaloul et al. (2023) investigated Mediterranean polypore species and observed that the ethanol extract of *I. cuticularis* showed the highest antioxidant activity in both ORAC and Folin–Ciocalteu assays. Their DPPH scavenging activity (EC₅₀ = 0.10 ± 0.00 µg/mL) was notably higher than in the present study, possibly due to differences in extraction methods, geographical origin, or strain variability.

Although *I. cuticularis* showed relatively low DPPH scavenging activity, its water extract demonstrated promising metal-chelating capacity. This activity is particularly important in oxidative stress mitigation, as metal ions like Fe^{2+} and Cu^{2+} can catalyze the formation of harmful free radicals. These findings suggest that *I. cuticularis* could serve as a potential source of natural antioxidants, especially for pharmaceutical and nutraceutical formulations targeting metal ion-associated oxidative stress. However, further research is necessary to optimize extraction techniques, identify the bioactive constituents, and explore possible synergistic effects.

CONCLUSIONS

Further biological activity studies are needed to especially from the understudied *I. cuticularis*, which may offer new prospects in mycochemistry and pharmaceutical development.

ACKNOWLEDGEMENT

This study is supported by TUBITAK 2218 domestic postdoctoral research fellowship program number 123C399 hosted by Muğla Sıtkı Koçman University. The authors would like to thank “TUBITAK 2218 domestic postdoctoral research fellowship program (BİDEB 2218)” for providing a postdoctoral fellowship to Cansu Korkmaz.

ABSTRACT

Reservoirs play a crucial role in freshwater ecosystems, serving key functions such as irrigation, drinking water supply, and flood control. Despite their importance, these artificial lakes are increasingly threatened by anthropogenic pollution. Macro elements like sodium (Na), magnesium (Mg), potassium (K), and calcium (Ca) are essential for both aquatic life and human health, and their elevated levels may indicate ecological stress or contamination. Atikhisar and Alibey Dam Lakes, located in the Marmara Region of Türkiye, are among the region's most vital reservoirs, supplying water to the provinces of Çanakkale and İstanbul. In this study, surface water samples were collected during the dry season of 2022 from both the inlet and outlet zones of each reservoir (a total of four sites). The concentrations of major macro elements—sodium (Na), magnesium (Mg), potassium (K), and calcium (Ca)—were measured, and potential macro elemental risks were assessed. Results indicated that Alibey Dam exhibited higher average concentrations of these elements compared to Atikhisar Dam. Overall, the elemental abundance in both reservoirs followed the trend: Na (81.066 µg/L) > Mg (31.434 µg/L) > Ca (21.867 µg/L) > K (6.353 µg/L).

Keywords: Atikhisar Dam Lake, Alibey Dam Lake, Macro elements, Water quality

INTRODUCTION

Macro elements such as sodium (Na), magnesium (Mg), potassium (K), and calcium (Ca) are essential constituents of natural waters and play vital roles in maintaining aquatic ecosystem function and water quality (Köse et al., 2013; Çiçek et al., 2013; Tokatlı and Helvacıoğlu, 2020; Ali et al., 2025). They are crucial for biological processes in both aquatic organisms and humans, including osmoregulation, enzyme activity, and bone development. However, elevated concentrations of these elements—especially under the influence of anthropogenic inputs such as agricultural runoff, industrial discharges, and urbanization—may lead to ecological imbalances and potential health risks. For instance, excessive sodium or magnesium levels can affect water taste, soil structure, and even plant and aquatic organism health. Therefore, regular monitoring of macro element concentrations in freshwater bodies is essential for early detection of pollution, sustainable water management, and the protection of ecological and human health (Arslan et al., 2012; Tokatlı et al., 2020; Din et al., 2023; Tokatlı et al., 2024; Ustaoglu et al., 2025).

Atikhisar Dam, located on Sarıçay Stream in the province of Çanakkale, was constructed between 1971 and 1975 primarily for irrigation and flood control. This earth-fill type dam has a body volume of approximately 1.99 million cubic meters and rises about 43 meters from the riverbed. Under normal water conditions, the reservoir has a surface area of 3.30 km² and a storage capacity of 40 hm³, supporting irrigation over nearly 5200 hectares of agricultural land (Anonymous, 2021a; Tokatlı et al., 2023). Similarly, Alibey Dam, situated on Alibey Stream in İstanbul, was built between 1975 and 1983 to supply drinking, utility, and industrial water.

Also designed as an earth-fill dam, it has a body volume of about 1.93 million cubic meters and a height of 30 meters. The reservoir holds up to 66.80 hm³ of water and spans a surface area of 4.66 km² at normal water levels, providing approximately 39 hm³ of potable water annually for the city (Anonymous, 2021b; Varol and Tokatlı, 2024).

This study aims to assess the macro elemental composition of two strategically important reservoirs in the Marmara Region—Atikhisar and Alibey Dam Lakes—which serve as key sources of irrigation and drinking water. By focusing on the concentrations of sodium (Na), magnesium (Mg), potassium (K), and calcium (Ca), the research seeks to highlight the current status of these essential yet potentially harmful elements when present in excess. Considering the ecological significance of reservoirs and the increasing pressure from anthropogenic influences, the study underscores the necessity of regular monitoring to ensure sustainable water resource management and the protection of ecosystem and public health.

MATERIALS AND METHODS

Water samples were systematically collected from both the inlet and outlet zones of Atikhisar and Alibey Dam Lakes, comprising a total of four sampling stations, during the dry season at the end of summer in 2022. These specific locations were selected to represent potential spatial variations in water quality between the entry and exit points of each reservoir system. The geographical layout of the study area, along with the precise coordinates of the sampling stations, is illustrated in Figure 1 to provide a clear spatial reference for the sampling design and to enhance the reproducibility of the study.

For macro-elemental analysis, the pH of each one-liter water sample was adjusted to approximately 2.0 by the addition of 2 mL of concentrated nitric acid (HNO₃) to prevent precipitation and ensure element stabilization. Subsequently, the samples were filtered using cellulose nitrate membrane filters with a pore size of 0.45 µm to remove particulate matter. The filtrates were then diluted to a final volume of 50 mL with ultrapure water to standardize the analytical conditions. Concentrations of calcium (Ca), magnesium (Mg), sodium (Na), and potassium (K) were quantified using an inductively coupled plasma mass spectrometer (ICP–MS, Agilent 7700xx) at the internationally accredited laboratory of Trakya University (certified under TS EN ISO/IEC 17025). All measurements were conducted in triplicate, and the mean values were reported to ensure analytical precision and reproducibility (EPA, 2001).

Figure 1. Study area and selected sampling locations

RESULTS AND DISCUSSION

The determined macro-elemental concentrations (Ca, Mg, Na, and K) at the designated sampling locations on both Atikhisar and Alibey Dam Lakes are presented in Figure 2. These values reflect the spatial distribution of the selected elements and provide insight into the ionic composition of the water bodies during the sampling period.

Notable spatial variations were observed between the two reservoirs. Sodium (Na) levels were markedly higher in Alibey Dam Lake, reaching a maximum of 128,219 $\mu\text{g/L}$ at station AB1, whereas the lowest value (25,690 $\mu\text{g/L}$) was recorded at AH2 in Atikhisar Dam Lake. Similarly, calcium (Ca) concentrations were substantially higher at AH1 (33,837 $\mu\text{g/L}$), indicating possible geological or anthropogenic influences. Mean concentrations across all stations were calculated as 81,066 $\mu\text{g/L}$ for Na, 31,434 $\mu\text{g/L}$ for Mg, 6,353 $\mu\text{g/L}$ for K, and 21,867 $\mu\text{g/L}$ for Ca.

Figure 2. Spatial distributions of macro elements

These data suggest distinct hydrochemical characteristics between the two dam lakes, particularly with respect to the distribution of sodium and calcium. The markedly higher sodium concentrations observed in Alibey Dam Lake, compared to Atikhisar Dam Lake, may be indicative of differences in the geological composition of the catchment areas, such as the presence of sodium-rich sedimentary formations or evaporitic deposits (Hem, 1985; Gibbs, 1970). Moreover, anthropogenic factors such as agricultural runoff, domestic wastewater discharge, and land use practices—particularly irrigation with sodium-enriched water—can further contribute to elevated sodium levels in surface waters (Zhou et al., 2016). On the other hand, the relatively higher calcium content in Atikhisar Dam Lake may be attributed to carbonate-rich lithologies in the surrounding catchment or enhanced dissolution processes of calcareous materials, which are common in Mediterranean hydrological regimes (Meybeck, 1987). Additionally, inflow dynamics, including flow rate, residence time, and seasonal variability, can significantly influence the dilution or concentration of dissolved ions in reservoirs (Lerman et al., 2007). Overall, the observed elemental distribution reflects the combined influence of natural and anthropogenic processes, underscoring the importance of basin-specific evaluations in understanding freshwater chemistry.

CONCLUSIONS

In this study, surface water samples were collected from the inlet and outlet zones of Atikhisar and Alibey Dam Lakes to determine the concentrations of key macro elements (Na, Mg, K, and Ca) during the dry season of 2022. The elemental composition of these two important reservoirs, which supply water to the provinces of Çanakkale and İstanbul, was evaluated in order to assess potential ecological and water quality risks. The results revealed that Alibey Dam Lake exhibited notably higher average concentrations of all analysed elements compared to Atikhisar, suggesting greater exposure to anthropogenic inputs or distinct geochemical characteristics. Among the studied elements, sodium was found in the highest concentrations, followed by magnesium, calcium, and potassium. These findings underscore the need for regular monitoring of elemental loads in freshwater reservoirs, as elevated macroelement levels can be early indicators of ecological stress and potential threats to both aquatic ecosystems and human water use.

ABSTRACT

To study the black carbon (BC) concentration in outdoor airborne fine particles with an aerodynamic diameter of 2.5 microns (PM_{2.5}), samples were collected at Burgas State University (42°31'41.6"N 27°26'58.7"E) during the winter of 2023 (6 February – 5 March). The BC content was analysed using a sequential sampler coupled with a real-time Black Carbon analyzer, which measures the samples directly on the sampling filter. The analyzer is equipped with an optical module that measures the attenuation of a laser beam.

A total of 28 PM_{2.5} samples were collected on 47 mm fiberglass filters in accordance with standard EN 12341:2023. The sampling duration was 24 hours per filter, with a flow rate of 2.3 m³·h⁻¹, resulting in a total air volume of 55 m³ passed through each filter. The black carbon concentration was recorded at 15-minute intervals. The detection limit of the method is 0.001 µg·m⁻³. The average BC concentration for the study period was 1.05 µg·m⁻³, with a maximum of 8.45 µg·m⁻³. Out of 2763 measurements, 726 (26.28%) were below the detection limit. The percentage content of BC in PM_{2.5} ranged from 1.57% to 13.17%, with an average value of 5.18%. The highest BC concentration was recorded on 16 February, associated with a wind speed of up to 5.7 m·s⁻¹ from the northeast-east and an atmospheric stability class of F (highly stable). This suggests a mobile emission source—intensive vehicle traffic near the monitoring point, indicating a local origin. The highest percentage of BC in PM_{2.5} was observed on 28 February. That day was characterized by high wind speeds (up to 8.8 m·s⁻¹) and neutral atmospheric stability (class D), suggesting long-range transport of pollutants. The south-west-west wind direction coincides with the urban area, where domestic heating is the primary emission source during the heating season. The largest number of measurements below the detection limit occurred on 25 February—37 out of 97 (38.14%) — a day with very high wind speeds (up to 8.8 m·s⁻¹), indicating enhanced dispersion of atmospheric pollutants. The highest daytime BC concentration was recorded on 15 February, a day with moderate wind speed from the south and a very stable atmosphere (class F). The highest nighttime BC concentration was observed on the same date downwind of a large residential district. The number of days with higher average daytime BC concentrations was equal to the number of days with higher average nighttime concentrations (14 each out of 28 24-hour samples). The overall average BC concentration was identical for both day and night during the study period, at 1.04 µg·m⁻³.

Keywords: Black carbon, PM_{2.5}, Air pollution, Air quality, Meteorology

INTRODUCTION

Ambient air quality is a key factor for human health and environmental protection (Johnson et al., 2022; Davronbekovna, 2023). Efforts by governments, non-governmental organizations, industry representatives, and the public have contributed to improved air quality in recent years (Zhang et al., 2022). Nevertheless, air pollution remains the greatest environmental health risk, causing disease, reducing quality of life, and leading to preventable deaths (Fuller et al, 2022; EEA, 2023).

This is a particular challenge for temperate regions, which are characterized by distinct seasonal changes and associated meteorological patterns, as well as the extensive use of heating fuels during winter (Megaritis et al., 2014). On a global scale, tracking studies have shown that air masses arriving at rural sites from Eastern Europe contained approximately twice the amount of BC compared to those from Western Europe (Ahlberg et al., 2023).

In Burgas Municipality, residential heating stoves account for 50% of PM_{10} emissions during the heating season, followed by various transport sources (over 30%), industry (about 16%), and agriculture (0.4%) (Todorov et al., 2025; Burgas Municipality, 2021). Black carbon is a significant component of airborne particles, particularly those with an aerodynamic diameter of 2.5 microns ($PM_{2.5}$).

The present study was conducted to determine the concentrations of BC in $PM_{2.5}$ during the 2023 heating season in the city of Burgas, Bulgaria. The monitoring site was selected as a background location representative of the entire municipality, minimizing direct influence from any specific local emission source.

MATERIAL AND METHOD

The concentration of BC in outdoor airborne $PM_{2.5}$ was studied at Burgas State University (42°31'41.6"N 27°26'58.7"E) during the winter of 2023 (6 February – 5 March) (Figure 1). The nearest pollution source is the intensive vehicular traffic on the E73 highway and Prof. Yakim Yakimov Street. However, a natural belt of vegetation between the roads and the monitoring point screens the direct impact. The nearest industrial site is Kronoshpan Bulgaria Ltd, located 2 km southwest of the sampling point. Toplofikatsiya Burgas JSC is situated 4 km to the west, and Lukoil Neftochim Burgas JSC is 8 km in the same direction (Hristova et al., 2023; Naydenova et al., 2022).

Figure 1. Location of the BC monitoring station on the territory of Burgas Municipality

Whatman® glass microfibre filters with a nominal pore size of 2 μm were used for the determination of $PM_{2.5}$ and BC mass concentrations (Zhang et al., 2022). Sample preparation involved conditioning the sampling filters in a controlled environment before gravimetric analysis (Wang et al., 2016). The filter mass was measured on three consecutive days to ensure

stability, after which they were loaded into filter holders and placed in the sampling equipment (Figure 2).

Figure 2. Pre-sampling filters

The Gianco BC₁ is a sequential fine particle sampler with an integrated real-time BC analyzer, which enables the simultaneous determination of PM and BC mass concentrations directly on the filter during the sampling. The instrument can autonomously sample particulate matter across different size fractions (PM_{2.5} and PM₁₀) for up to 21 days (Dunea et al., 2016). It is equipped with state-of-the-art data logging solutions, including RFID technology, local data download via USB, and remote data access and device control via a LAN connection.

The BC concentration is determined by an optical module that measures the attenuation (not reflection) of a laser beam (Yu et al., 2017). The Gianco BC₁ is the first commercial solution to utilize a laser attenuation method (LAM) based on reflectometry, as opposed to the more common transmittance-based techniques. The concentration of black carbon is derived from the optical absorption coefficient, which is directly related to the light-absorbing properties of atmospheric particles (Cyrus et al., 2003).

Unlike other market analyzers that rely on transmittance, the Gianco BC₁'s patented technology is based on reflectometry (Heal et al., 2017). This innovative approach provides a linear correlation with the absorption coefficient used in the BC concentration calculation. A key advantage of this design is the seamless integration of the BC sensor into the sequential sampler, allowing for real-time, on-site monitoring of both PM and BC throughout the sampling operation (Figure 3).

Figure 3. Giano BC₁ sampling device for determining the concentration of black carbon in PM_{2.5}

Following the aspiration of 55 m³ of air over a 24-hour period (a measurement procedure conducted in accordance with standard BDS EN 12341:2023), the loaded filters were conditioned for 24 hours in a controlled environment (Figure 4) (Ciupek et al., 2024). The mass of each filter was then measured gravimetrically on three consecutive days to ensure stability. The PM mass concentration was calculated based on the mass gain of the filter and the exact volume of air that had passed through it. The black carbon concentration was determined at 15-minute intervals throughout each sampling period. For direct comparison with the gravimetric PM_{2.5} data, the BC concentrations are reported as a 24-hour average mass concentration in $\mu\text{g}\cdot\text{m}^{-3}$.

Figure 4. Post-sampling filters

RESULTS AND DISCUSSION

The analysis of the average daily concentrations of BC in $PM_{2.5}$ (Graph 1) shows that the highest value was recorded on Thursday, 16 February ($8.45 \mu\text{g}\cdot\text{m}^{-3}$), and the lowest on Monday, 6 February ($0.147 \mu\text{g}\cdot\text{m}^{-3}$). The average concentration for the study period was $1.05 \mu\text{g}\cdot\text{m}^{-3}$. The highest BC concentration on 16 February, associated with a wind speed of up to $5.7 \text{ m}\cdot\text{s}^{-1}$ from the northeast-east and an atmospheric stability class of F (highly stable) (Graph 3). This suggests a mobile emission source—intensive vehicle traffic near the monitoring point, indicating a local origin.

Graph 1. BC concentration in $PM_{2.5}$, $\mu\text{g}\cdot\text{m}^{-3}$

Graph 2 presents the percentage of BC in $PM_{2.5}$. The calculated values range from 1.6% to 13.2%. The lowest content is on Sunday, February 26 and the highest - on 28 February. That day was characterized by high wind speeds (up to $8.8 \text{ m}\cdot\text{s}^{-1}$) and neutral atmospheric stability (class D), suggesting long-range transport of pollutants (Graph 4). The south-west-west wind direction coincides with the urban area, where domestic heating is the primary emission source during the heating season.

Graph 2. BC content in $PM_{2.5}$, %

Graph 3. Meteorological data for 16.02.2023

Graph 4. Meteorological data for 28.02.2023

BC concentration data were recorded at 15-minute intervals, resulting in approximately 100 valid measurements per 24-hour period. Graphs 5 and 6 present the lowest non-zero and the highest recorded concentrations for each sampling day, respectively. The lowest minimum concentration ($0.001 \mu\text{g}\cdot\text{m}^{-3}$) was recorded on Sunday, 26 February, while the highest minimum concentration ($0.128 \mu\text{g}\cdot\text{m}^{-3}$) was observed on Saturday, 4 March. Conversely, the lowest maximum concentration ($1.633 \mu\text{g}\cdot\text{m}^{-3}$) was recorded on Wednesday, 8 February, and the highest maximum concentration ($8.451 \mu\text{g}\cdot\text{m}^{-3}$) was measured on Sunday, 5 March. The meteorological conditions for this day are characterized by low wind speeds (up to $3.6 \text{ m}\cdot\text{s}^{-1}$), without a clearly defined direction and a prevailing strong stable atmosphere category (F) (Graph 8).

Graph 5. Min daily BC concentration PM_{2.5}, µg.m⁻³

Graph 6. Max daily BC concentration in PM_{2.5}, µg.m⁻³

Graph 7. Meteorological data for 17.02.2023

Graph 8. Meteorological data for 05.02.2023

The emission intensity of various urban pollution sources also exhibits diurnal variation (Jalava et al., 2015). Consequently, the data were analyzed by separating the light (daytime) and dark (nighttime) periods of the 24-hour cycle. At the beginning of the study period (6 February), sunrise occurred at 07:18 and sunset at 17:26, resulting in a day length of 10 hours and 7 minutes. On the final sampling day (5 March), sunrise was at 06:37 and sunset at 18:02, resulting in a day length of 11 hours and 25 minutes. The results of this diurnal analysis are presented in Graph 9. The greatest predominance of nighttime over daytime BC concentration was recorded on Wednesday, 15 February. On this day, the average nighttime concentration was $2.19 \mu\text{g}\cdot\text{m}^{-3}$, compared to a daytime average of $0.91 \mu\text{g}\cdot\text{m}^{-3}$. The strongest inverse relationship, where daytime concentrations exceeded nighttime values, was observed on Saturday, 25 February. On this day, the average daytime BC concentration was $1.68 \mu\text{g}\cdot\text{m}^{-3}$, while the nighttime average was $0.81 \mu\text{g}\cdot\text{m}^{-3}$. The highest daytime BC concentration was recorded on 17 February, a day with very high wind speed (up to $8.8 \text{ m}\cdot\text{s}^{-1}$) from the east and a neutral/stable atmosphere (equal classes C and E) (Graph 7). The highest nighttime BC concentration was observed on 5 February - low wind speeds (up to $3.6 \text{ m}\cdot\text{s}^{-1}$), without a clearly defined direction and a prevailing strong stable atmosphere category (F) (Graph 8).

Graph 9. Average Day/Night BC concentrations, $\mu\text{g.m}^{-3}$

Given the fact that the main share of $\text{PM}_{2.5}$ emissions in the territory of Burgas Municipality is due to the burning of wood in residential stoves during the heating season, an unexpectedly large percentage of measured black carbon values below the detection limit was reported. The data by day is presented in Chart 10.

Graph 10. Percentage of daily data below the detection limit, %

The highest number of such cases was recorded on Saturday, February 25 (38.14%). On that day, the wind was very high and northeast-easterly, suggesting ideal conditions for the dispersion of atmospheric pollutants and the self-purification ability of the air in the coastal urban area (Graph 11).

Graph 11. Meteorological data for 25.02.2023

CONCLUSIONS

Analysis of the processed data reveals that even during the winter months, when the domestic stoves are the primary source of emissions, the meteorological conditions characteristic of coastal sea areas can contribute to the better dispersion of pollutants, thereby improving air quality and the quality of life for the population. However, local authorities continue to seek environmentally friendly solutions to mitigate air pollution in urban areas.

ABSTRACT

Emissions of gaseous air pollutants and particulate matter from anthropogenic and natural sources contribute to global climate change, which in turn leads to health and environmental risks. Air quality guidelines focus on fine particulate matter with an aerodynamic diameter of 2.5 μm (PM_{2.5}), nitrogen oxides (NO_x), sulfur dioxide (SO₂), and other pollutants to reduce air pollution. The Gothenburg Protocol recognizes black carbon (BC) as a major component of PM_{2.5}. However, air quality standards do not specifically target it, and it is not part of any climate protocol, revealing a significant gap in strategies. The data on the concentration of BC and both PM fractions – 2.5 and 10 microns were analysed by the scientific team on the territory of Burgas State University “Prof. Dr. Asen Zlatarov” (42°31'41.6"N 27°26'58.7"E). PM sampling was carried out according to the EN 12341:2023 standard, and BS was analysed by measuring the reflectivity of the laser beam. The meteorological data is from the Burgas Airport station, which provides high quality data representative of the studied territory and measures atmospheric pressure (hPa), air temperature and dew point (°C), relative air humidity (%) and wind speed (m.s⁻¹), taking average values for 24 hours, which is the duration of PM sampling. The concentrations of other atmospheric pollutants were recorded at the DOAS monitoring station, which operates on the principle of Differential Optical Absorption Spectroscopy and records the concentrations of ozone (O₃), nitrogen dioxide (NO₂), sulphur dioxide (SO₂), and benzene. The processing of the data from the correlation analysis between the concentrations of BC and PM shows a strong degree of correlation with PM_{2.5} (0.69) and a moderate with PM₁₀ (0.49). One of the reasons is that the 10-micron fraction also contains the 2.5-micron fraction, which in turn contains condensable particles (secondary aerosols) to a higher degree. This is also the reason why BC is analysed primarily in the 2.5-micron fraction. A positive moderate degree of correlation was recorded between the concentrations of BC and nitrogen dioxide (0.66), which is an indicator of high-temperature emission sources (industrial factories and vehicles during warm start). The negative moderate degree of correlation with ozone (- 0.61) shows probable absorption of secondary atmospheric pollutants obtained during chemical processes in the atmosphere, as this also applies to benzene, although the correlation with it is negative and very weak (- 0.06). No correlation with sulfur dioxide was recorded, which indicates that the emission sources do not use fuels containing sulfur (coal or diesel cars). A strong degree of correlation is recorded between aircraft and wind speed (-0.79). Its average value for the studied period is 5.06 m.s⁻¹, which is the reason for the dispersion of local emission sources and does not show the impact of distant ones. Although the weak degree of correlation with air temperature (- 0.23) is characteristic of the reduction of the amounts of solid fuels used in residential stoves when temperatures rise. The correlations with dew point and relative humidity are very weak (- 0,15 and 0,14).

Keywords: Black carbon, PM, Air pollution, Air quality, Meteorology, Correlation

INTRODUCTION

The quality of the components of the environment is interconnected and also affects the living organisms that inhabit them (Deshmukh, 2024). From an agricultural point of view, not only the plants, preparations used and the quality of the soil are decisive (Suchkov et al., 2022). Pollutants contained in the air can be transported and affect through dry precipitation (in the case of substances with a higher density than air) or through rainwater, thus changing the quality of the soil, the natural reservoirs used for irrigation, as well as directly affecting agricultural production in the growth phases (Borghi et al., 2023).

From this point of view, the study of the concentration of BC and its ability to retain other atmospheric pollutants, according to the size of its pores and the influence of meteorological parameters, is of utmost importance (Rumpel et al., 2006; Lagasio et al., 2025). If the structure of black carbon contains retained compounds such as carbon, sulfur or nitrogen oxide (D'Amico et al., 2025), falling into a humid environment (fog, rain or dry precipitation in a reservoir or humid soil), this would lead to a change in the acidic reaction of the environment (pH) (Abd et al., 2025).

The influence of meteorological parameters is also extremely important, because through them, preliminary measures can be taken to minimize the negative impact of atmospheric pollutants and lead to more sustainable eco- and agrarian systems (Girotti et al., 2025).

The present study was conducted to determine the concentrations of BC in PM_{2.5} during the 2023 heating season in the city of Burgas, Bulgaria and the correlation between BC content in airborne PM_{2.5}, concentration of other pollutants, and meteorological conditions. The monitoring site was selected as a background location representative of the entire municipality, minimizing direct influence from any specific local emission source.

MATERIAL AND METHOD

The correlation between BC content in airborne PM_{2.5}, concentration of other pollutants, and meteorological conditions was studied through measurements of BC and both fractions of fine dust particles on the territory of Burgas State University "Prof. Dr. Asen Zlatarov" (42°31'41.6"N 27°26'58.7"E), the DOAS - RIEW Stations (42°30'36.7"N 27°28'07.6"E) and the meteorological parameters from Burgas Airport (42°33'59.5"N 27°31'04.6"E). The location of the three stations is presented in Figure 1. The sampling period and data collection were organized during the winter of 2023 (6 February – 5 March).

The sampling station on the university's territory has two devices for determining the concentration of the two fractions of fine dust particles (2.5 and 10 microns), in accordance with standard EN 12341:2023 (Ciupek et al., 2024) and maximum permissible concentration according to Bulgarian and European legislation (Zaitseva et al., 2020), and the concentration of black carbon, which has not yet permission level. The method for PM is standard gravimetric measurement for the determination of the PM₁₀ or PM_{2.5} mass concentration of suspended particulate matter. The concentration of black carbon is derived from the optical absorption coefficient, which is directly related to the light-absorbing properties of atmospheric particles (Cyrus et al., 2003).

The DOAS - RIEW station is owned by the Ministry of Environment and Water of the Republic of Bulgaria and measurements of atmospheric pollutant concentrations are carried out using an OPSIS device, operating on the principle of Differential Optical Absorption

Spectroscopy, a scientific technique for measuring atmospheric pollutants using light absorption (Baroncelli et al., 2025). Concentrations of ozone, sulfur dioxide, nitrogen dioxide, and benzene are measured. Each of these pollutants has a maximum allowable concentration limit for the atmospheric air of populated areas (Richelle, 2025).

The weather station at Burgas Airport uses Vaisala cells and records the values of atmospheric pressure, air temperature, dew point, relative humidity, wind speed and direction, visibility, cloud cover density at three levels and specific meteorological phenomena every 30 minutes (Díaz-Bedoya et al., 2025).

Figure 2 presents the three monitoring stations, and Table 1 presents the maximum permissible concentrations of the analyzed atmospheric pollutants.

Figure 2. Data stations

Table 1. Maximum permissible concentrations of atmospheric pollutants, according

	1 hour	8 hours	24 hours	1 year
PM _{2.5}	-	-	-	20 µg.m ⁻³
PM ₁₀	-	-	50 µg.m ⁻³	40 µg.m ⁻³
Black carbon	-	-	-	-
Ozone	-	120 µg.m ⁻³	-	-
Sulfur dioxide	350 µg.m ⁻³	-	125 µg/m ³	-
Nitrogen dioxide	200 µg.m ⁻³	-	-	40 µg.m ⁻³
Benzene	-	-	-	5 µg.m ⁻³

RESULTS AND DISCUSSION

The data on the measured concentrations of atmospheric pollutants on the territory of the university are presented in Table 2. The concentrations of BC are in the range 0,147 - 1,376 µg.m⁻³ with average value of 0,621 with standard deviation of 0,311. The PM_{2.5} concentrations

are in the range 3,454 – 23,149 $\mu\text{g.m}^{-3}$ with average value of 13,066 with standard deviation of 5,537. For PM_{10} the range of measurement concentrations is 5,784 – 48,926 $\mu\text{g.m}^{-3}$ with average value of 24,197 with standard deviation of 11,135. None of the measured values exceed the norm.

Table 2. Concentration of Black carbon, $\text{PM}_{2.5}$ and PM_{10} at the sampling point University

No	Date	BC [$\mu\text{g.m}^{-3}$]	$\text{PM}_{2.5}$ [$\mu\text{g.m}^{-3}$]	PM_{10} [$\mu\text{g.m}^{-3}$]
1	6.2.2023	0,147	7,211	10,636

25	2.3.2023	0,497	9,272	14,680
26	3.3.2023	0,58	9,029	14,731
27	4.3.2023	0,862	16,604	25,390
28	5.3.2023	0,871	18,544	28,163

The most frequently reported concentrations for black carbon were in the range of 0.03 - 0.4 $\mu\text{g.m}^{-3}$, for $\text{PM}_{2.5}$ – 9 $\mu\text{g.m}^{-3}$ and 18 $\mu\text{g.m}^{-3}$, and for PM_{10} – 15 $\mu\text{g.m}^{-3}$ and 30 $\mu\text{g.m}^{-3}$ (Graph 1).

Graph 1. Statistical distribution of BC, PM_{2.5}, PM₁₀ concentrations, $\mu\text{g.m}^{-3}$

The data from the correlation analysis between Black carbon concentrations and the two particle fractions is presented in Table 3. A very strong correlation was reported between the small and large particle fractions, strong between BC and PM_{2.5} and medium between BC and PM₁₀, indicating that BC is mainly contained in the small fraction.

Table 3. Correlation analysis between BC, PM_{2.5} and PM₁₀

	BC [$\mu\text{g.m}^{-3}$]	PM _{2.5} [$\mu\text{g.m}^{-3}$]	PM ₁₀ [$\mu\text{g.m}^{-3}$]
BC [$\mu\text{g.m}^{-3}$]	1		
PM _{2.5} [$\mu\text{g.m}^{-3}$]	0,69	1	
PM ₁₀ [$\mu\text{g.m}^{-3}$]	0,49	0,82	1

The data on the measured concentrations of atmospheric pollutants at DOAS - RIEW station are presented in Table 4. The concentrations of O₃ are in the range 52,8 - 86,15 $\mu\text{g.m}^{-3}$ with average value of 68,41 with standard deviation of 8,54. The NO₂ concentrations are in the range 9,8 – 45,37 $\mu\text{g.m}^{-3}$ with an average value of 22,95 with standard deviation of 10,23. For SO₂ the range of measurement concentrations is 2,65 – 21,02 $\mu\text{g.m}^{-3}$ with average value of 5,88 with standard deviation of 5,16. The benzene concentrations are in the range 1,29 - 1,51 $\mu\text{g.m}^{-3}$ with average value of 1,44 with standard deviation of 0,04. Again, none of the measured values exceed the norm.

Table 4. Concentration of O₃, NO₂, SO₂ and Benzene at the sampling point DOAS-RIEW

Nº	Date	O ₃ [µg.m ⁻³]	NO ₂ [µg.m ⁻³]	SO ₂ [µg.m ⁻³]	Benzene [µg.m ⁻³]
1	6.2.2023	67,98	11,210	2,770	1,44

27	4.3.2023	55,17	28,270	7,440	1,43
28	5.3.2023	58,17	22,310	5,440	1,48

The most frequently reported concentrations for ozone were at 70 µg.m⁻³, for NO₂ – 14 µg.m⁻³, for SO₂ – 3 µg.m⁻³ and benzene – 1,4 µg.m⁻³ (Graph 2).

Graph 2. Statistical distribution of O₃, NO₂, SO₂ and Benzene concentrations, µg.m⁻³

The data from the correlation analysis between Black carbon concentrations and O₃, NO₂, SO₂ and benzene is presented in Table 5. A moderate negative correlation was reported between BC and ozone. The likely reasons for this are : Absorption and Deposition (BC particles can absorb ozone and its precursors from the air, removing them from the atmosphere and leading to decreased ozone concentrations), Reduced Photolysis (BC absorbs solar radiation, which can reduce the photolysis (breaking down by light) of precursor molecules like NO₂, leading to lower ozone formation rates) and Vertical Stratification (At higher altitudes, BC aerosols in vertically stratified air masses can be negatively correlated with surface ozone due to downward mixing after the planetary boundary layer (PBL) develops). Correlation between BC and NO₂ is moderate again, which may be an indication of high-temperature emission processes. There is not correlation between BC and SO₂. The reason is the constantly low concentration of sulfur dioxide. It is the same with benzene.

Table 5. Correlation analysis between BC, O₃, NO₂, SO₂ and Benzene

	BC [µg.m ⁻³]	O ₃ [µg.m ⁻³]	NO ₂ [µg.m ⁻³]	SO ₂ [µg.m ⁻³]	Benzene [µg.m ⁻³]
BC [µg.m ⁻³]	1				
O ₃ [µg.m ⁻³]	-0,61	1			
NO ₂ [µg.m ⁻³]	0,66	-0,58	1		
SO ₂ [µg.m ⁻³]	0,00	-0,24	0,49	1	
Benzene [µg.m ⁻³]	-0,06	-0,11	-0,09	-0,11	1

The meteorological data From Airport Burgas station (LBBG15655) are presented in Table 6. The values of atmospheric pressure are in the range 1007,77 - 1038,63 hPa with average value of 1023,00 with standard deviation of 8,89. The air temperature is in the range -0,94 – 15,88°C with average value of 6,15 with standard deviation of 5,08. For dew point the range of measurement values is -7,94 – 8,44°C with average value of 0,44 with standard deviation of 5,25. The relative humidity is in the range 45,88 - 86,63% with average value of 69,20 with standard deviation of 11,19. The wind direction values are in the range 63,33 – 272,83 degree with average value of 187,91 with standard deviation of 65,03. The last parameter, wind speed is in the range 2,46 – 10,27 m.s⁻¹ with average value of 5,06 with standard deviation of 1,99.

The most frequently reported values for Atmospheric pressure is 1018 hPa, for Air temperature – 7°C, for Dew point - 4 °C, for Relative humidity – 64% and for Wind speed – 4,5 m.s⁻¹ (Graph 3).

Graph 3. Statistical distribution of Atmospheric pressure, Air temperature, Dew point, Relative humidity and Wind speed

The data from the correlation analysis between Black carbon concentrations and Atmospheric pressure, Air temperature, Dew point, Relative humidity, Wind speed and direction is presented in Table 7. A strong negative degree of correlation is reported between BC and Wind speed. The likely reasons for this are : Pollutant Dispersion (wind acts as a natural cleaning mechanism, dispersing pollutants over a wider area and reducing their concentration in a specific location) and Reduced Accumulation (higher wind speeds prevent the accumulation of pollutants, such as black carbon, by moving them away from emission sources and diluting them into the atmosphere). The correlations between BC and the other meteorological parameters are weak or very weak.

Table 7. Correlation analysis between BC, AtmP, T, DewP, RH, Wwind dir and Wind speed

	BC [$\mu\text{g.m}^{-3}$]	Atm P [hPa]	T [°C]	DewP [°C]	RH [%]	Dir [Degree]	Speed [m.s^{-1}]
BC [$\mu\text{g.m}^{-3}$]	1						
Atm P [hPa]	0,23	1					
T [°C]	-0,23	-0,86	1				
DewP [°C]	-0,15	-0,86	0,87	1			
RH [%]	0,14	-0,20	-0,03	0,45	1		
Dir [Degree]	0,02	0,05	0,10	-0,27	-0,73	1	
Speed [m.s^{-1}]	-0,79	-0,02	0,09	-0,04	-0,30	0,10	1

CONCLUSIONS

The results obtained from the analysis of air quality data and meteorological parameters during the winter period show that the maritime climate, characterized by its strong winds, leads to an improvement in air quality, as well as through the absorption of ozone in its carbon. Decisions related to the high correlation with $\text{PM}_{2.5}$ and nitrogen dioxide can be a reduction in emissions from residential stoves and motor vehicles. Such measures have already been successfully undertaken and implemented by the Municipality of Burgas.

ABSTRACT

Microalgae are attracting interest in many sectors, particularly agriculture, energy, environment, food, medicine, and cosmetics, due to their high biomass production capacity and ability to grow in various environments. The environmental, economic, and social sustainability of products derived from microalgae is one of the most discussed topics today. The cultivation system for microalgae is the most important factor influencing their long-term viability. Microalgae are typically grown in two systems: open ponds and closed systems, also known as photobioreactors. Open systems, like open raceway ponds, natural lakes, and lagoons, have direct contact with the atmosphere and are generally simpler. In contrast, photobioreactors are closed systems that produce microalgae under controlled conditions. In this study, these two fundamental systems commonly used in microalgae cultivation were compared in terms of sustainability. Open-system microalgae production offers greater economic benefits; it is less environmentally sustainable. The primary causes of this are the high risk of contamination and evaporation resulting from these systems' contact with the environment. Although product yield is low in these systems, more resilient species can typically be cultivated. Because closed systems produce microalgae under more controlled conditions and have a higher biomass yield, they have been found to be more beneficial for environmental sustainability. However, because of setup capital and operating costs, microalgae production in these systems is more costly. To summarize, both open and closed systems for microalgae cultivation have benefits and drawbacks in terms of environmental and economic sustainability. As a result, rather than selecting a single system, working with hybrid systems and focusing on operational conditions to local needs and resources should be viewed as the key to microalgae sustainability.

Keywords: Microalgae, cultivation system, photobioreactors, economic sustainability, environmental impacts, social sustainability

INTRODUCTION

Today, increasing energy demand, depletion of resources, and global environmental issues are driving growing interest in renewable and sustainable resources. In this context, microalgae have become one of the most promising sources for sustainable production systems due to their high biomass yield, rapid growth, ability to utilize CO₂, and capacity to synthesize various valuable products (Brooke et al., 2025). The sustainability of the system in which microalgae are grown has a direct impact on the sustainability of the final product (Ugya et al., 2025). Microalgae are grown in both open and closed environments. The advantages and disadvantages of each system in terms of sustainability are different. In the study, open and

closed systems were compared, and it was determined which system was better suited for microalgae cultivation under what conditions.

MICROALGAE

Microalgae are microscopic organisms with photosynthetic capabilities. They can multiply rapidly in various environments (Singh & Saxena, 2015). Their high biomass yields, ability to use atmospheric carbon dioxide, and ability to synthesize a variety of valuable products have made them an important biomass source in the biotechnology, food, energy, and health industries. Microalgae can produce a variety of products, including biofuels from lipids, food supplements from proteins, pigments, and antioxidants. They also have important roles in environmental applications like wastewater treatment and carbon capture (Chisti, 2020).

MICROALGAE CULTIVATION SYSTEMS

Microalgae production is typically divided into two types: open and closed systems. The type of system used depends on the product, economic resources, environmental conditions, and technical capabilities.

Open systems are simple systems in which microalgae are grown in an open environment. Shallow ponds are the most commonly used type of open system. These systems are typically installed outside, have an open top, and are capable of absorbing carbon dioxide from the air (Costa et al., 2019). The main advantage of these systems is that they are simple and inexpensive to set up and operate. The use of natural light and ventilation lowers the energy consumption of these systems. The primary disadvantage of open systems is that they are completely exposed to the outside world. This can make microalgae susceptible to contamination from bacteria, fungi, or unwanted algae species. Furthermore, environmental factors such as temperature, light, and wind cannot be controlled in these systems. This lowers production efficiency. Growth rates are low, and product quality varies in these systems (Zuccaro et al., 2020).

Closed systems, also known as photobioreactors, are systems for cultivating microalgae in a controlled environment. These systems are made up of tubes, pipes, and transparent panels like glass or plastic (Zuccaro et al., 2020). These systems get their light and air from the outside. The most significant advantage of closed systems is that production conditions are entirely controllable. Light, temperature, and pH levels can be kept constant. This translates to higher yields and higher-quality products. The risk of contamination is extremely low. Closed systems allow for greater microalgae production per unit area. The primary disadvantage of closed systems is their high installation and operating costs (Jerney & Spilling, 2020). Additionally, technical knowledge and experience are required for the system to function.

SUSTAINABILITY OF MICROALGAE CULTIVATION SYSTEMS

Microalgae cultivation systems' sustainability is not a one-dimensional issue; it needs to be assessed alongside resource consumption, environmental effects, expenses, and societal advantages.

Energy and water consumption are important factors for microalgae cultivation systems when evaluating environmental sustainability. The carbon footprint of closed systems is increased by the high energy requirements for lighting, CO₂ injection, and continuous mixing. Even though open ponds use less energy, their lower yields may have a greater environmental impact per unit of product (Gurreri et al., 2023). Water consumption is a major issue for both systems. In this sense, one notable strategy that could reduce costs and environmental impacts is the use of wastewater for microalgae cultivation.

Nutrient inputs used in microalgae cultivation are another factor that impacts sustainability. Industrial fertilizers are commonly used to supply nutrients like nitrogen and phosphorus. This imposes additional environmental costs in terms of fossil fuel consumption and greenhouse gas emissions. However, in recent years, the use of waste streams as nutrient sources, particularly urban and industrial wastewater, has provided circular economy-compatible solutions (Branco-Vieira et al., 2020). This promotes wastewater treatment while also minimizing the environmental impact of nutrient inputs.

Economically, the method of utilizing microalgal biomass is critical. The use of microalgae biomass for biofuel production is economically limited due to high production costs. Applications aimed at high-value-added products, on the other hand, appear to be more profitable. Microalgae derivatives used in cosmetics, pharmaceuticals, and food additives provide a higher revenue potential as well as a shorter return on investment (Acién et al., 2017; Pérez-López et al., 2018).

Microalgae production, on the other hand, can provide both environmental and economic benefits, as well as social benefits. The establishment of local production facilities has the potential to create jobs in rural areas while also contributing to regional development (Josa & Garfi, 2023).

CONCLUSIONS

Consideration of the environmental, economic, and social aspects of microalgae cultivation systems' sustainability reveals notable variations amongst them. Although open systems are inexpensive and simple to set up, they have poor environmental efficiency; closed systems, on the other hand, are more controllable and effective in terms of the environment, but their high energy consumption limits their economic viability. On a social level, both systems provide opportunities for local production and employment; however, hybrid solutions seem to be more sustainable.

The development of hybrid systems, integration of renewable energy, and more efficient use of waste streams can all improve the sustainability of microalgae technologies.

ABSTRACT

In this study we were interested in the synthesis and evaluation of the antimicrobial and antioxidant activities of a highly reactive malonic ester derivative, the bispentachlorophenyl ester of malonic acid, with the aim of employing it in the preparation of heterocyclic mesoionic compounds containing a pyrimidine ring. Due to its high reactivity, this malonic ester undergoes rapid condensation with amine derivatives under mild conditions to produce pyrimidinium betaines, and the reaction proceeds within minutes.

Microbiological assays performed using the disk diffusion method demonstrated that this malonic ester exhibits significant antimicrobial activity against the target germs: *Bacillus subtilis*, *Salmonella enterica*, *Mucor ramannianus* and *Candida albicans* in a concentration-dependent manner. Furthermore, the assessment of its radical-scavenging capacity through the 2,2-diphenyl-1-picrylhydrazyl (DPPH) assay revealed that the compound reduces the DPPH free radical only slowly, most likely due to its limited solubility in organic solvents.

Keywords: Malonic esters derivatives , Bispentachlorophenyl ester of malonic acid, Synthesis,

INTRODUCTION

Bacteria have been reported as the cause of potentially life-threatening infections worldwide (Berber et al., 2003; Mitscher et al., 1999). Therefore, the development of new antimicrobial drugs is undoubtedly crucial, and ongoing intensive research is focused on the design of new agents (Narasimhan et al., 2007). Free radicals are major products of lipid oxidation and have been implicated in more than a hundred diseases (Thomas, 1995). Antioxidants may therefore play a crucial role in disease prevention due to their ability to scavenge reactive free radicals (Gülçin et al., 2004).

Malonic ester derivatives are widely used in organic chemistry as intermediates for the synthesis of diverse compounds. Organochlorine derivatives, in particular, represent a class of organic compounds with broad applications in agriculture, industry, medicine, and domestic use (Manoranjan et al., 2020). They exhibit remarkable biological activities and distinctive chemical properties, attributable to the presence of chlorine in their molecular structure—an essential element of antibacterial and antifungal agents (Trudgill et al., 1971, Monde et al., 1998). Consequently, these compounds are extensively applied as pesticides, insecticides, and fungicides in agriculture (Adelodun et al., 2020).

In this study, we focused on the synthesis of a highly reactive chlorinated malonic ester derivative, dipentachlorophenyl phenylmalonate, and on the evaluation of its antimicrobial activity using the disc diffusion method (Balouiri et al., 2016). This compound is widely employed in organic synthesis due to the strong electron-withdrawing effect of the chlorophenyl groups (Dvortsak et al., 1976, Kappe et al., 1971). The presence of ten chlorine atoms in its structure is expected to enable under very mild conditions and within a shorter time with other reagents (Dvortsak et al., 1976, Malki et al. 2014), The study also examined the antioxidant potential of this ester using the DPPH assay, with the aim of exploring its potential valorization as an antioxidant

MATERIAL AND METHOD

Chemical part

The compound investigated in our study, dipentachlorophenyl phenylmalonate **2**, can be prepared according to the procedure reported by (Huhn et al., 1976), by the action of phosphorus pentachloride on phenylmalonic acid **1** (Scheme 1).

Scheme1. Synthesis of dipentachlorophenyl phenylmalonate **2**

Biological part

Antimicrobial activity

The antibacterial and antifungal activities of the synthesized malonic ester (**2**) were evaluated using the agar diffusion method, also known as the disc diffusion assay (Balouiri et al., 2016).

The microbial strains tested included:

Bacteria (Gram-): *Salmonella enterica* (S.e), (Gram+): *Bacillus subtilis* (B.s) ATCC 6633

Fungi: *Fusarium oxysporum* lini (F.o.l), *Mucor romannianus* (M.r) NRRL 1829 *Fusarium culmorum* (F.c)

Yeasts: *Candida albicans* (C.a) IPA 200.

The tested microorganisms were obtained from the Laboratory of Microbial Systems Biology (LBSM), École Normale Supérieure, Kouba, Algiers, Algeria. The culture medium used was ISP2 [International Streptomyces Project], as recommended by Shirling and Gottlieb (1966). Its composition was as follows: 4 g glucose, 4 g yeast extract, 10 g malt extract, 10 g agar, and 1 L distilled water. The pH of the medium was adjusted to 7.2.

The diameters of the inhibition zones surrounding the discs containing the test samples were measured; a positive antimicrobial activity was indicated by a clear zone around the disc corresponding to the inhibition of microbial growth (Gülçin et al., 2008).

Gentamicin, fluconazole, and amphotericin B were used as reference antibiotic and antifungal agents, respectively.

Antioxidant activity

The antioxidant activity of a compound corresponds to its ability to resist oxidation. In this context, the antioxidant activity of the synthesized malonic ester **2** was evaluated *in vitro* using the 2,2-diphenyl-1-picrylhydrazyl (DPPH) assay (Blois, 1958; Brand-Williams, 1995), with slight modifications. The principle of this method is based on the measurement of the radical scavenging ability of DPPH in methanol solution. The addition of an antioxidant to the DPPH solution leads to its decolorization, which is directly proportional to the antioxidant capacity of the tested compound, thus indicating the reduction of the radical to diphenylpicrylhydrazine (DPPHH). This decolorization can be monitored spectrophotometrically by measuring the decrease in absorbance at 517 nm. Solutions of test compounds of increasing concentrations were prepared, the absorbance relative to the negative control containing only the DPPH solution is measured by spectrophotometry at 517 nm. The positive control was represented by a solution of a standard antioxidant, butylated hydroxytoluene (BHT), whose absorbance was measured under the same conditions as the samples. All tests were performed in triplicate. The percentage of DPPH inhibition (I%) was calculated according to the following formula (Harififar et al., 2007; Malki et al., 2019).

$$I\% = [(Abs\ contr\hat{o}le - Abs\ test) / Abs\ contr\hat{o}le] \times 100$$

Abs : Absorbance at 517 nm

RESULTS AND DISCUSSION

Dipentachlorophenyl phenylmalonate **2** was synthesized as described in scheme 1. It was obtained in the form of a white solid with good yield. This compound was characterized through various analytical methods and its structure was confirmed (Malki et al., 2011). The physical and spectroscopic characteristics of ester **2** are summarized in Table 1. The presence of two chlorophenyl groups in its structure makes the carbonyl groups highly reactive toward nucleophilic agents, including amidine derivatives (Malki et al., 2015).

Table 1. Physical and spectroscopic characteristics of malonic ester **2**

Compound	Aspect	T _{fus} (°C)	Yield (%)	λ _{max} (nm) (ε) (Dioxanne)	IR (KBr) ν̄ (cm ⁻¹)
Dipentachlorophenyl phenylmalonate 2	White solid	226-230	87	303 (5050)	1815 (ester) 1360 ,1390 (penta- chlorophényle

Antimicrobial activity

Antimicrobial substances are defined as compounds used either to destroy microorganisms or to inhibit their growth, including antibiotics as well as other antibacterial and antifungal agents.

In the present study, malonic ester **2** was tested *in vitro* to evaluate its antibacterial and antifungal activities using the disc diffusion method (Balouiri, 2016). The activity against the tested microorganisms was assessed based on the presence or absence of inhibition zones. The diameters of the inhibition zones for bacteria, fungi, and yeasts are presented in Tables 2 and 3, respectively.

Table 2. Zones of inhibition of bacteria obtained with the synthesized malonic ester 2

Concentration (µg/disque)	Inhibition zone diameters * (mm)	
	Gram + bacteria	Gram- bacteria

F. o.l : *Fusarium oxysporum lini*, *M.r* : *Mucor romannianus*,

F.c : *Fusarium culmorum*

C.a : *Candida albicans*

The results presented in Table 2 demonstrate that malonic ester 2 displays a pronounced antibacterial activity against the Gram-positive bacterium (*B.s*) with inhibition zones ranging from 12 to 16 mm, while exhibiting comparatively lower activity against the Gram-negative strain *Salmonella enterica* (*S.e*). These findings indicate that both Gram-positive and Gram-negative bacteria are susceptible to this compound.

Regarding antifungal activity (Table 3), the highest inhibition zone was observed against the filamentous fungus *Mucor romannianus* (*M.r*), followed by a relatively weak effect against the yeast *Candida albicans* (*Ca*). No activity was detected against the fungi *Fusarium culmorum* (*F.c*) and *Fusarium oxysporum lini* (*F.o.l*).

Furthermore, it was observed that this activity increases proportionally with the concentration of the tested ester. The presence of ten chlorine atoms, structural elements frequently associated with antibacterial and antifungal properties, within the ester structure is probably responsible for its antimicrobial activity (Naumann, 2000). Figure 1 illustrates the antibiogram of the malonic ester 2 tested against the Gram-positive bacteria *Bacillus subtilis* (*B.s*) and the fungus *Mucor romannianus* (*M.r*).

Figure 1. Antibiogram of the malonic ester **2** tested against the Gram-positive bacteria *Bacillus subtilis* (left) and the fungus *Mucor ramannianus* (right).

Antioxidant Activity

The *in vitro* antioxidant potential of the synthesized malonic ester **2** was assessed using the DPPH radical scavenging assay. This radical was one of the first free radicals employed to investigate the structure–antioxidant activity relationship of phenolic compounds (Olszowy-Tomczyk, 2021).

The reduction kinetics of DPPH of the tested ester, Dipentachlorophenyl phenylmalonate **2** at a concentration of 25 $\mu\text{g/mL}$ and the reference antioxidant BHT were monitored over time until reaching the effective time value (TE50), corresponding to a 50% reduction in the DPPH activity (absorbance) in the reaction medium (Małgorzata, 2019). The obtained kinetic profile revealed a time-dependent antiradical activity. The longer the reaction time, the higher the percentage of DPPH inhibition. Figures 2a and 2b illustrate this effect in the case of malonic ester **2** and the standard antioxidant BHT.

Figure 2a. % of DPPH inhibition over time by malonic ester **2**

Figure 2b. % of DPPH inhibition over time by BHT

From the curve plotting the relationship between the percentage of DPPH inhibition (I% DPPH) and reaction time, the effective time (TE50) required to reduce 50% of DPPH was determined by graphical interpolation. It was observed that ester **2** reduced the DPPH free radical very slowly. At, $t = 3$ h, the % inhibition of the DPPH radical is only 33% and the is of the order of 19.2h, which is considerably slower compared to BHT, whose TE50 was about 75 min. The TE50 values, expressing the effective time required for trapping and reducing 50% of DPPH in methanolic solution, are summarized in Table 4.

Table 4. Effective time (TE50) values of malonic ester **2** and BHT.

Compound	TE50
Malonic ester 2	19.2 h
BHT	75min

As shown in Table 4, malonic ester **2** exhibits antioxidant activity; however, its efficiency was markedly lower than that of the standard antioxidant BHT. The presence of a hydrogen atom adjacent to two carbonyl groups in malonic ester **2** may account for its DPPH radical scavenging activity. In the presence of the DPPH free radical, this hydrogen atom is transferred to the radical, which is subsequently converted into a stable DPPHH molecule (Molyneux, 2004; Sanchez-Moreno, 1998). This process leads to a decrease in both the free radical concentration and the absorbance over the course of the reaction, until the hydrogen-donor antioxidant capacity is exhausted (Villano et al., 2007).

Regarding the molecular structures, the high efficiency of BHT is primarily attributed to the presence of hydroxyl groups in its structure. In contrast, the absence of such groups in the structure of the ester and its poor solubility in organic solvents, are likely responsible for its comparatively weak antioxidant potential. It has been demonstrated that molecules such as ascorbic acid, butylated hydroxyanisole (BHA), and butylated hydroxytoluene (BHT) display strong radical scavenging activity owing to the hydroxyl groups in their structures, which which readily donate hydrogen atoms to DPPH radicals (Bondet et al., 1997).

CONCLUSION

In this study, we reported a simple synthetic route to obtain a highly reactive malonic ester derivative, dipentachlorophenyl phenylmalonate in good yield. This ester exhibits notable antibacterial and antifungal activities in a concentration-dependent manner. In addition, it demonstrates a modest antioxidant effect against the DPPH free radical, which can be attributed to its limited solubility in organic solvents. Therefore, further investigations are needed to determine the optimal conditions for its potential applications in the agri-food and pharmaceutical–medical fields.

ABSTRACT

This study focuses on evaluating the quality of surface water table in the Oued M'Zab region to determine its suitability for agricultural use. The adopted methodology is based on spatial analysis of water salinity and sodicity, as well as classification according to irrigation standards. The results indicate that the groundwater exhibits poor quality for irrigation, with significant risks of soil salinization. This calls for strict irrigation management to promote salt leaching. Additionally, the alkalization risk ranges from low to moderate, with potential sodium toxicity for sensitive crops.

Keywords: Risk, Irrigation, Surface water table, Soils, Oued M'Zab,

INTRODUCTION

Agriculture represents the largest consumer of water resources. These resources, depending on the regions from which they originate and their possible contact with sources of pollution, display highly diverse characteristics (Bouaroudj, 2012). Consequently, the quality of irrigation water varies according to the nature and the concentration of dissolved salts. An increase in salt content is responsible for several problems affecting both soil and plants. The most frequently encountered issues are associated with salinity, sodicity, specific ion toxicity, as well as other problems linked to excess nitrogen and bicarbonates (Daddi Bouhoun, 1997).

In southern Algeria, particularly in the M'Zab Valley, the climatic water deficit is such that resorting to irrigation constitutes a vital necessity for agricultural production. Groundwater represents the only resource available to meet the needs of irrigation and various domestic uses, which highlights the importance of thoroughly assessing the quality of these waters and protecting them against any risk of contamination (Taleb Bahmed, 2008).

The aim of this study is to evaluate the quality of irrigation water from the surface water table of the M'Zab Valley through the determination of electrical conductivity (E.C) and the Sodium Adsorption Ratio (S.A.R), with a view to their use in agriculture.

MATERIAL AND METHOD

Our study was carried out in the M'Zab Valley, located 600 km south of the capital Algiers. Administratively, it belongs to the province of Ghardaïa (Benhedid, 2015; Achour *et al.*, 2016).

The M'Zab Basin covers an area of approximately 5,000 km², with poorly defined boundaries in its eastern part. The Oued M'Zab flows roughly from west to east over 320 km, from the Botma-Rouila region at an altitude of 750 m to the Sebkhet Safioune at 107 m, with a relatively steep slope between Ghardaïa and Bounoura (Dubief, 1953). Its width ranges from 1.50 to 2.35 km upstream and gradually decreases downstream to reach 0.55 km south of the town of El Atteuf (Achour, 2014).

The main water resources in this area are of groundwater origin. They are contained in two types of aquifers: the shallow Quaternary alluvial aquifer and the deep Continental Intercalaire aquifer (Bensaha *et al.*, 2011; Benhedid, 2015).

In order to properly assess the quality of water from the surface water table of the Oued M'Zab for irrigation purposes, our study was conducted at four stations corresponding to the municipalities of Daya Bendahoua, Ghardaïa, Bounoura, and El Atteuf, distributed along the Oued M'Zab from upstream to downstream (Fig. 1).

A total of forty-five traditional wells, distributed from upstream to downstream of the Oued M'Zab with a variable number per study station, were sampled for physico-chemical analyses. This allowed for the classification of these waters according to the irrigation standards established by the Riverside Laboratory and modified by Durand (1983). The number of sampling sites in the stations of Daya Bendahoua, Ghardaïa, Bounoura, and El Atteuf was 5, 29, 6, and 5 respectively (Fig. 1).

Water samples were collected following the standards of Rodier *et al.* (2009), during the high-water period from February to March 2013. The parameters studied were electrical conductivity (E.C.) and the Sodium Adsorption Ratio (S.A.R). Electrical conductivity was measured using a conductimeter (L.F. 538 type). The S.A.R was calculated from the concentrations (in meq/L) of Na⁺, Ca²⁺, and Mg²⁺ in the water according to the following formula:

$$S.A.R. = \frac{Na^+}{\sqrt{(Ca^{++} + Mg^{++})/2}}$$

Sodium (Na⁺) was determined using a flame emission spectrophotometer, while calcium (Ca²⁺) and magnesium (Mg²⁺) were analyzed by titrimetry.

To determine the spatial distribution of the risks of soil salinization and alkalinization due to the waters of the shallow aquifer, the results obtained were represented in the form of maps generated using Surfer 11 software, based on a Google Earth satellite image (2013).

Figure 1. Location of the surface water table wells in Oued M'Zab

RESULTS AND DISCUSSION

Water Salinity

The classification of water salinity proposed by the Riverside Laboratory and modified by Durand (1983) reveals the presence of three classes (Fig. 2 and Table 1):

Class C3 ($750 < E.C < 2250 \mu S/cm$): This class includes only four samples, representing 9% of all analyzed water points. These correspond to wells P5 in Daya Bendahoua, P12 and P33 in Ghardaïa, and P37 in the Bounoura station. Such waters are unsuitable for soils with restricted drainage. Even with adequate drainage, special salinity control practices may be necessary, and only salt-tolerant crops can be cultivated.

Class C4 ($2250 < E.C < 5000 \mu S/cm$): This class comprises the majority of wells, representing 62%, which indicates that most waters from this aquifer exhibit very high salinity. These waters are generally unsuitable, except in highly permeable soils with good drainage, combined with excess irrigation to ensure strong leaching of salts from the soil. Crops grown under these conditions must be highly salt-tolerant.

Class C5 ($5000 < E.C < 20000 \mu S/cm$): This class corresponds to most of the wells located in the El Atteuf station (80%) and to 50% of those in Bounoura, while it represents only 29% of all wells overall. In general, the surface water table of Oued M'Zab are characterized by very high salinity: 62% of the wells, excessive salinity: 29%, and high salinity: 9%.

The spatial variation of water E.C shows an increase from upstream to downstream, following the direction of water flow. Salt accumulation in the aquifer is favored by irrigation leaching, wastewater discharge, and the geological layers crossed by the wells. In addition, excessive pumping of irrigation water from certain wells can lead to salt concentration, while reduced pumping or non-use of wells during winter allows for a decrease in water salinity due to dilution from rainfall.

According to Daddi Bouhoun (1997) and Couture (2004), high water E.C may cause an excess of soluble salts in the soil, thereby reducing water absorption by plants (osmotic pressure phenomenon), and consequently, reducing plant growth depending on crop tolerance to salinity.

Table 1. Salinity classes of the surface water table of Oued M'Zab

Salinity Stations	C3		C4		C5	
	High salinity		Very high salinity		Excessive salinity	
	Number of wells	%	Number of wells	%	Number of wells	%
Daya Bendahoua	1	20	3	60	1	20
Ghardaïa	2	7	22	76	5	17
Bounoura	1	17	2	33	3	50
El Atteuf	-	-	1	20	4	80
Total	4	9	28	62	13	29

Figure 2. Map of soil salinization risk in the Oued M'Zab

Water Sodidity

The Riverside classification makes it possible to determine the risk of soil alkalization by class, based on the S.A.R and E.C values of the waters, using the Riverside diagram (Fig. 4, 5, 6). This classification reveals the presence of four classes (Table 2; Fig. 3) (Durand, 1983):

Class S1: This class represents only 24.5% of all water points. These waters can be used for the irrigation of almost all soils with little risk of alkalization.

Class S2: The majority of wells belong to this class, representing 62.5%, particularly the waters of the El Atteuf wells. The risk of soil alkalization is significant in fine-textured soils with high cation exchange capacity. However, this water is suitable for coarse-textured soils or organic soils with good permeability.

Class S3: This class corresponds to waters that may induce a hazardous alkalinity in most soils. Their use requires proper drainage, strong leaching, and the addition of organic matter. It represents 11% of the wells.

Class S4: The risk of alkanization is very high. Such waters can be used for irrigation only if their low salinity allows for the addition of soluble calcium or if the soil already contains sufficient amounts. This class corresponds only to well P40, representing 2%.

Table 2. Sodicity classes of the surface water table of Oued M'Zab

Figure 3. Map of soil alkalization risk in the Oued M'Zab

Classification of Irrigation Waters

The Riverside diagrams, modified by Durand (1983) (Fig. 4, 5, 6), together with the determination of alkalization risk, allow for the classification of irrigation waters based on the measured parameters of E.C and S.A.R. This approach enabled us to identify six classes of water in the M'Zab Valley, as follows (Table 3):

Class C3-S1: Waters with high salinity and low alkalization risk. This class includes only four wells, representing 9% of the total.

Class C4-S1: Waters with very high salinity and low alkalization risk, representing 15.5% of the analyzed water points.

Class C4-S2: Waters with very high salinity and medium alkalization risk. This class represents 47% of the wells, including 55% of those in Ghardaïa.

Class C5-S2: Waters with excessive salinity and medium alkalization risk, accounting for 15.5%, and representing 80% of the wells in El Atteuf.

Class C5-S3: Waters with excessive salinity and high alkalization risk, accounting for 11% of all wells, including 20% in Daya Bendahoua and 14% in Ghardaïa.

Class C5-S4: This class corresponds only to well P40 and represents 2% of the wells. These waters exhibit excessive salinity and very high alkalization risk.

Table 3. Water classes of the surface water table of the Oued M'Zab

Stations Water classes	Daya Bendahoua		Ghardaïa		Bounoura		El Atteuf		Total	
	Nb	%	N°	%	N°	%	N°	%	N°	%

Figure 6. Irrigation water quality in the Bounoura and El Atteuf stations as a function of E.C and S.A.R

CONCLUSIONS

The study of the quality of the surface water table of the Oued M'Zab, with reference to irrigation water standards, revealed that these waters are highly saline. This situation reflects both the effect of lithology and the agro-urban anthropogenic impact, which contribute to the increase in the concentrations of certain elements.

The agricultural classification of these waters indicates that they are of poor quality for irrigation, particularly downstream in Bounoura and El Atteuf. In general, the waters present a risk of soil salinization, which requires careful irrigation management to ensure adequate salt leaching and thereby avoid salt stress for crops. The alkalization risk is moderate, with a possible risk of sodium toxicity for sensitive crops.

Our study highlights the degradation of groundwater resources due to agricultural and urban activities in the M'Zab Valley. It is necessary to optimize the use of these groundwater resources and to raise farmers' awareness in order to improve agricultural practices. Further research is essential in the region

to monitor water quality and assess agricultural and environmental impacts. Additional management measures are also needed with a view to safeguarding the ecosystem in support of sustainable development in the M'Zab Valley.

ABSTRACT

The present study aimed to evaluate the agronomic behavior and qualitative performance of three winter wheat varieties (Katarina, Biharia, Apache) cultivated under rainfed conditions in the pedoclimatic context of Gălbinași, Buzău County, Romania, during the 2023–2024 agricultural year. The experiment was carried out on a 45 ha experimental field and applied a conventional cultivation technology including soil tillage and phased fertilization, tested in three variants: control (no additional fertilization), two-phase fertilization, and three-phase fertilization. Data collection included plant density at emergence and harvest, thousand-kernel weight, number of grains per spike, test weight, yield per hectare, and grain quality indices (moisture, protein content, wet gluten content). Statistical analysis (ANOVA and linear regression) demonstrated the significant influence of fertilization on plant density and kernel weight ($p < 0.05$), with a moderate correlation between fertilization level and yield ($R^2 = 0.58$). The variety Katarina recorded the highest stability and yield potential (7711.4 kg/ha with three-phase fertilization), followed by Biharia and Apache. Grain quality was superior for Katarina and Biharia regarding protein and gluten content, while Apache showed lower values under low fertilization. The results highlight the potential of phased nitrogen fertilization to mitigate drought stress effects and improve both yield and grain quality under the restrictive climatic conditions of southeastern Romania. The study provides valuable recommendations for optimizing winter wheat cultivation technologies in areas with similar pedoclimatic conditions.

Keywords: soil tillage, fertilization, wheat, drought, climate change

INTRODUCTION

Agriculture is one of the oldest human occupations, emerging with the transition from nomadism to sedentary living (Guş & Tianu, 1991). Throughout the evolution of human societies, agriculture has diversified and improved, being strongly influenced by technological and social progress. A defining moment was the invention of the plough, evolving from simple wooden beams to modern ploughs with mechanical traction and multiple moldboards (Panaitescu, 2016; Panaitescu & Niță, 2011). The expansion of mechanization, the use of chemical fertilizers, and the introduction of genetic engineering have significantly increased yields but have also generated negative environmental impacts (Budoï & Penescu, 1996; Cakpo et al., 2025).

In Romania, studies by the National Research and Development Institute for Soil Science, Agrochemistry and Environmental Protection have highlighted the degradation of soil quality through

erosion, acidification, salinization, compaction, and chemical pollution (Patriche et al., 2023a; Patriche et al., 2023b; Stănilă, 2023). Globally, the intensification of conventional agricultural practices has contributed to biodiversity loss, water pollution, and contamination of agri-food products (Gagiu et al., 2023; Gagiu et al., 2025). Therefore, adapting these practices is essential to protect ecosystems and human health (Budoï & Penescu, 1996; Calistru et al., 2024).

In recent decades, climate change has become a major challenge for global agriculture. The global average temperature has increased by approximately 1.7°C compared to the pre-industrial period and is projected to rise by up to 2.7°C in the coming decades (Bandoc & Prăvălie, 2015; Moise, 2023; European Environment Agency, 2023). In temperate continental regions, such as Muntenia, these changes translate into prolonged droughts, uneven precipitation distribution, heatwaves, torrential rains, hail, and extreme winds (Niță et al., 2024; European Environment Agency, 2023). The Gălbinași commune, Buzău County, frequently faces such phenomena, requiring the adaptation of agricultural technologies to the new conditions (Gagiu et al., 2025).

Winter wheat (*Triticum aestivum* L.) remains one of the key crops in Romania due to its economic value and its ability to adapt to local soil and climate conditions (Panaitescu, 2016; Popescu et al., 2023). The choice of suitable variety, the application of adapted cultivation technologies, and soil conservation are key factors in achieving stable and high-quality yields (Guş & Tianu, 1991; Cakpo et al., 2025).

The aim of this study is to analyze the behavior and suitability of three winter wheat varieties grown under non-irrigated conditions in Gălbinași, Buzău County, during the 2023–2024 agricultural year, characterized by extreme climatic conditions. The applied cultivation technology was conventional, including soil tillage (Cakpo et al., 2025), and phased fertilization varied depending on variety and treatment (Calistru et al., 2024). For each variety, three experimental variants were tested: control (no additional phased fertilization), two-stage phased fertilization, and three-stage phased fertilization.

The specific objectives of the study are: to compare the agronomic behavior of the three wheat varieties under identical technological and climatic conditions; to analyze the performance of the varieties under conventional systems in terms of agronomic efficiency and conservation of soil and water resources, within the context of sustainable agriculture; to formulate technical recommendations on variety selection and cultivation technology adapted to the specific conditions of Gălbinași, with the possibility of extending the results to areas with similar pedoclimatic conditions; to reduce production costs and achieve high and superior quality yields.

MATERIAL AND METHOD

The study was conducted during the 2023–2024 agricultural year on a 45-hectare experimental plot belonging to Denagro Martrans company, located in Gălbinași, Buzău County, in a region representative of large-scale farming in southeastern Romania. The area's climate is excessively continental, characterized by hot, dry summers with maximum temperatures reaching 39°C, and cold winters with frequent blizzards and temperatures dropping below -20°C. Annual precipitation is low and unevenly distributed, while the average annual temperature is around 11.5°C. The soils in the experimental area are classified as cambic chernozems, with a loamy texture in the upper horizon and loamy-silty texture in intermediate horizons, developed on calcareous loess deposits, and with a physical structure suitable for conventional agricultural practices.

The biological material consisted of three winter wheat (*Triticum aestivum* L.) varieties: Apache, Katarina, and Biharia. Apache is an early, awnless variety with medium height, excellent lodging resistance, high tillering and winter hardiness, and good tolerance to foliar diseases,

particularly rusts and fusarium. Katarina, also early and awnless, has strong emergence vigor, good winter hardiness, high yield potential, and resistance to major diseases. Biharia is a semi-late variety, with short stature and short awns, notable for its drought, lodging, and disease resistance, as well as for its very good tillering capacity.

The cultivation technology followed conventional system principles, including primary ploughing, soil loosening and leveling, followed by sowing at a 12.5 cm row spacing with the same seeding rate for all experimental variants. The experiment comprised nine variants, three for each variety, organized as follows: a control variant (without additional phased fertilization, to highlight the biological potential and the effect of the previous crop), a variant with two-stage phased fertilization, and a variant with three-stage phased fertilization. Plant protection treatments (herbicides, fungicides, and insecticides) were uniformly applied across all variants, ensuring that the observed differences could be attributed exclusively to the genotypes and fertilization regime.

To evaluate the agro-productive performance of the three varieties, observations and measurements were carried out throughout the growing season. These included plant density at emergence and harvest (expressed as plants/m²), thousand kernel weight (TKW), determined by weighing a standardized sample of mature grains, number of grains per spike, determined by manual harvest and counting, hectoliter weight expressed in kg/hl according to SR 13574:2010 standard, and average yield per hectare, calculated based on the weight of grains relative to the cultivated area. Additionally, grain quality parameters (moisture, protein, and gluten content) were analyzed using appropriate laboratory equipment.

To analyze differences among the experimental variants and assess the influence of fertilization under the water stress conditions characteristic of the study year, the data were subjected to statistical analysis. Analysis of variance (ANOVA) was used to test the significance of differences between treatments, and linear regression models were applied to evaluate the relationship between fertilization level, yield, and lack of precipitation. The significance level was set at $p \leq 0.05$. Data processing was performed using SPSS statistical software (version 26) and Microsoft Excel.

RESULTS AND DISCUSSION

In the experiment, soil preparation for the winter wheat crop followed agrotechnical principles aimed at maximizing the productive potential of the crop. Winter wheat performs best when preceded by early-harvest species that leave the soil rich in nitrogen and other essential nutrients, thereby enabling timely execution of primary soil work. In all nine experimental variants, the preceding crop was pea, a legume highly valued agronomically due to its ability to fix atmospheric nitrogen and leave the soil weed-free, enriched with plant residues that, once incorporated, increase organic matter content and stimulate soil microbiological activity.

The experiment was conducted on a total area of 45 hectares, equally divided among the three tested wheat varieties: Apache, Katarina, and Biharia. Each variety was cultivated on 15 hectares, further split into three experimental variants of 5 hectares each: control (without additional fertilization), two-stage phased fertilization, and three-stage phased fertilization.

For the control variant, the crop relied solely on residual nitrogen and nutrients left in the soil after the pea crop, to assess the biological potential of the varieties without the influence of additional fertilization. In the fertilized variants, the first application coincided with sowing in the first decade of October, with 300 kg/ha of Duofertil Eurocereal 34 (N, P, S) from Timac, a product designed to mobilize and protect nutrients and stimulate root development thanks to the Mappa Duo and XCK complex. The second application, applied to both the two- and three-stage fertilization variants, took place on March 18, using Sulfammo 25 Mappa Duo at a rate of 150 kg/ha, a solid fertilizer with 25%

nitrogen and 31% sulfur trioxide. The three-stage fertilization variant also received an additional foliar treatment on April 28, at flag leaf emergence, applying 30 l/ha of In-Folen (19% nitrogen, 5% magnesium oxide, 10% sulfur trioxide), aimed at enhancing enzymatic activity and optimizing grain quality parameters.

Soil preparation included deep ploughing at approximately 25 cm depth in the second decade of August, using a Lemken EurOpal 5 plough, with the purpose of turning over the furrow, incorporating plant residues, and ensuring good soil aeration and loosening. The ploughing depth was adjusted according to the soil's moisture level and the amount of plant residue.

Figure 1 – Fertilization scheme of the three winter wheat varieties across experimental variants

The climatic conditions recorded during the growing season were characterized by positive temperature anomalies and a significant precipitation deficit, which increased the importance of the applied technology and fertilization regime. The climatic data recorded in the experimental area are presented in figure 2. Monthly average temperatures were significantly higher than the multiannual normal, with notable differences in December 2023 and January 2024, where temperatures exceeded the normal values by approximately 5°C.

Regarding precipitation, the total amount accumulated during the 2023–2024 agricultural year was 311.4 mm, which is 114.4 mm below the multiannual average (425.8 mm). Severe water deficits were recorded especially during the active growing months (March–June), with a total of 116.7 mm compared to the estimated requirement of 280–320 mm for optimal wheat development at this stage. Only January and April recorded values above the normal average, but the surplus was insignificant.

Figure 2 – Evolution of precipitation and temperatures in the study area, Gălbinași locality, during the 2023–2024 agricultural year

Seedbed preparation was carried out on October 4, 2023, with a single pass of the Vaderstad TopDown 400 cultivator, which broke down the plough furrows, loosened, and leveled the soil to facilitate optimal seed-to-soil contact. The seeds used came from certified seed lots (C1 biological category), with a physical purity of 99.80% for Biharia and Katarina and 98.70% for Apache, and a germination capacity of 97%. The thousand kernel weight (TKW) was 42 g for Biharia and Katarina, and 40 g for Apache.

Before sowing, the seeds were mandatorily treated with Austral Plus (500 ml/100 kg seed), a broad-spectrum insecto-fungicide. Sowing took place on October 6, 2023, at a row spacing of 12.5 cm and a sowing depth of 4 cm, with a seeding rate of 390 germinable seeds/m², corresponding to approximately 210 kg seed/ha.

Weed control was achieved through integrated preventive methods and chemical treatments. The main weeds identified were *Sinapis arvensis*, *Cirsium arvense*, *Centaurea cyanus*, *Chenopodium album*, *Galium aparine*, *Capsella bursa-pastoris* (dicotyledonous species), and *Avena fatua*, *Poa annua* (monocotyledonous species). Control of monocotyledonous weeds was achieved with Starane Super (0.4 l/ha), applied on April 24 together with insecto-fungicides. Dicotyledonous weeds were controlled with Biathlon 4D (0.07 kg/ha) and adjuvant Dash HC (1 l/ha), applied at the 6–8 leaf stage on May 11.

Plant protection against diseases was carried out in two stages: the first treatment with Evolus (1 l/ha) on April 24, and the second with Falcon Pro (0.9 l/ha) on May 11, providing preventive, curative, and eradicated protection. Pest control was initially ensured by seed treatment, followed by two chemical treatments: Lamdex Extra (0.3 kg/ha, April 24) and Delmetros 100SC (0.15 l/ha, May 11).

Harvesting was performed on June 28, 2024, with a Deutz Fahr C7206 combine equipped with a cereal header. The grain moisture at harvest ranged between 11.5% and 12.6%. After threshing, the straw was baled, and the grain was transported and stored in designated facilities.

The yield results showed a clear influence of the fertilization regime and variety used. The average yields obtained were: for Katarina, 7,711.4 kg/ha (three fertilizations), 6,425.1 kg/ha (two fertilizations), and 5,689.6 kg/ha (control); for Biharia, 6,543.6 kg/ha (three fertilizations), 5,689.6

kg/ha (two fertilizations), and 4,615.4 kg/ha (control); for Apache, 6,108.7 kg/ha (three fertilizations), 4,848.4 kg/ha (two fertilizations), and 3,365.4 kg/ha (control). These results confirm the benefits of split nitrogen application, especially under challenging climatic conditions and significant water deficits.

Plant density at emergence was determined using standardized methods by counting plants per linear meter over 10 rows with three repetitions for each experimental variant at the first true leaf stage. The average values show a positive influence of fertilization on final crop density.

For Katarina, the average plant density for the three-fertilization variant was 308 plants/m² (min. 27, max. 34 plants), for two fertilizations 302 plants/m² (min. 27, max. 33 plants), and for the control 288 plants/m² (min. 26, max. 34 plants). For Biharia, the values were 305 plants/m² (three fertilizations), 300 plants/m² (two fertilizations), and 283 plants/m² (control), with individual ranges between 26 and 34 plants/m². For Apache, densities were 300 plants/m² (three fertilizations), 299 plants/m² (two fertilizations), and 276 plants/m² (control), ranging from 26 to 33 plants/m².

The results show a clear tendency for increased plant density as fertilization intensity increased across all three varieties. This is attributed to improved germination vigor and seedling emergence, resulting from the additional nutrient (mainly nitrogen) supply applied at sowing. The data also indicate good emergence uniformity, with consistent values between repetitions, highlighting seed quality and effective seedbed preparation.

Spike density at harvest was determined by counting spikes per linear meter over 10 rows, with three repetitions for each variety and fertilization variant. The average values showed a clear influence of fertilization on spike density, demonstrating the positive effect of nitrogen supplementation on tillering capacity and plant survival up to harvest.

For Katarina, spike density was 567 spikes/m² (three fertilizations), 531 spikes/m² (two fertilizations), and 508 spikes/m² (control). For Biharia, values were 532 spikes/m² (three fertilizations), 508 spikes/m² (two fertilizations), and 491 spikes/m² (control). For Apache, values were 509 spikes/m² (three fertilizations), 480 spikes/m² (two fertilizations), and 474 spikes/m² (control). The observed minimum–maximum ranges per row were 44–62 spikes for Katarina, 42–61 spikes for Biharia, and 40–62 spikes for Apache, confirming moderate variability but with a clear tendency for increased spike density with increased fertilization.

These results support the hypothesis that split fertilizer application leads to higher final plant densities at harvest, due to reduced plant mortality and stimulated secondary tillering during the growing season.

To validate the significance of the differences between experimental variants for spike density at harvest, raw data (10 repetitions per variant) were subjected to analysis of variance (ANOVA). The ANOVA test showed extremely significant differences between varieties and fertilization variants ($F(2,87) = 12.28$; $p < 0.0001$). These data confirm that the fertilization regime had a strong impact on spike density at harvest, mainly by stimulating secondary tillering and reducing plant mortality under the severe water deficit conditions recorded in the 2023–2024 agricultural year. A directly proportional relationship between increased fertilization intensity and spike density was consistently observed across all three studied varieties.

The results confirm the hypothesis that split nitrogen application, adapted to wheat phenological stages, optimizes crop architecture and contributes to yield stability under challenging climatic conditions.

To provide a detailed representation of experimental data variability, spike density at harvest was also illustrated using a boxplot diagram (Figure 3). This enabled visualization of the full distribution of the 10 repetitions for each variety and fertilization variant. The boxplot highlights medians, interquartile ranges, and potential outliers, providing a comprehensive picture of result consistency. A clear trend of higher average density for Katarina, followed by Biharia and Apache, was observed, in line with the previously calculated averages. Slightly higher variability for Biharia was noted, possibly due to greater sensitivity to water stress conditions.

Figure 3 – Boxplot of spike density distribution at harvest for the three wheat varieties

To better understand the relationship between fertilization level and final spike density at harvest, the average data obtained for the three varieties were subjected to linear regression analysis. Fertilization was coded ordinally (0 = control, 1 = two fertilizations, 2 = three fertilizations). The regression model revealed a positive relationship between increasing fertilization intensity and final spike density. The resulting regression line indicated a clear trend of increased crop density with additional fertilizer application. The coefficient of determination ($R^2 = 0.45$) suggests that approximately 45% of the variation in spike density at harvest can be attributed to differences in the applied fertilization regimes.

This result supports the conclusions of the ANOVA test and confirms the hypothesis that phased fertilization, adapted to the phenological requirements of the crop, significantly contributes to reducing plant mortality and stimulating secondary tillering, thereby optimizing crop architecture under water stress conditions.

Figure 4 – Regression between fertilization level and spike density at harvest

The determination of the thousand kernel weight (TKW) was carried out by repeated weighing of samples taken from all experimental variants, in order to identify the influence of the fertilization regime on this essential quality indicator. The results showed a clear tendency for TKW to increase with the intensification of fertilization for all three varieties studied. For Katarina, the average values were 44 g (three fertilizations), 42 g (two fertilizations), and 40 g (control). For Biharia, values were 44 g (three fertilizations), 40 g (two fertilizations), and 35 g (control). For Apache, the values were 43 g, 39 g, and 31 g, respectively.

To validate the statistical significance of the differences, raw data were subjected to ANOVA testing. The analysis revealed significant differences between varieties and variants ($F(2,60) = 7.35$; $p = 0.0014$). These results demonstrate the strong influence of split fertilizer application on thousand kernel weight, particularly under the difficult pedoclimatic conditions of the 2023–2024 agricultural year, characterized by precipitation deficit and water stress. It can be concluded that judicious application of nitrogen fertilization, aligned with crop phenological stages, optimizes the grain filling process and contributes to achieving superior grain quality.

To provide a detailed characterization of data variability from the determination of thousand kernel weight (TKW), a visual analysis was performed using a boxplot (Figure 5). This representation highlighted the distribution of values obtained for the three studied varieties: Katarina, Biharia, and Apache. The boxplot reveals clear differences between the three genotypes, with Katarina showing the lowest internal variability, which may indicate superior stability of this trait under unfavorable pedoclimatic conditions. In contrast, Biharia and Apache showed greater dispersion of values, suggesting a stronger reaction to abiotic stress or interaction with the applied fertilization technology.

Distribution of thousand kernel weight (TKW) for the three wheat varieties

Figure 5 – Boxplot of thousand kernel weight (TKW) distribution for the three wheat varieties

To quantify the relationship between fertilization level and thousand kernel weight (TKW), a linear regression model was applied to the average values obtained for the three varieties and the three fertilization regimes. The results indicated a positive relationship between increased fertilization intensity and higher TKW values. The regression analysis produced a coefficient of determination (R^2) of 0.69, meaning that approximately 69% of the variation in thousand kernel weight can be explained by the applied fertilization level. This demonstrates a strong and predictable influence of the nutritional regime on grain quality. The results are fully consistent with those highlighted by the ANOVA test and the boxplot analysis, further supporting the hypothesis that phased fertilization, adapted to the specific requirements of the crop, plays a decisive role in improving the quality parameters of the wheat harvest.

The yield per hectare was determined based on the harvest obtained for each variety and experimental variant. The results showed a clear trend of yield increase with the intensification of the fertilization regime.

For the Katarina variety, yields of 7,711.4 kg/ha (three fertilizations), 6,425.1 kg/ha (two fertilizations), and 5,689.6 kg/ha (control) were recorded. For Biharia, yields were 6,543.6 kg/ha (three fertilizations), 5,689.6 kg/ha (two fertilizations), and 4,615.4 kg/ha (control). For Apache, values of 6,108.7 kg/ha, 4,848.4 kg/ha, and 3,365.4 kg/ha were recorded for the same variants.

To test the significance of the differences between varieties and fertilization variants, an analysis of variance (ANOVA) was applied. Although notable value differences were observed, the statistical test indicated a lack of statistical significance ($F(2,6) = 1.96$; $p = 0.22$). This is explained by the absence of multiple biological replicates for each variant, as the data were obtained from a single experimental plot per treatment. Therefore, these results must be interpreted primarily descriptively, without rigorous statistical validation. Nevertheless, the clear trend of increased yield with increasing fertilization level is evident and correlates with the other agro-productive data previously analyzed (spike density at harvest, number of grains per spike, thousand kernel weight), confirming the

effectiveness of phased fertilization even under the difficult climatic conditions of the 2023–2024 agricultural year.

To highlight the trend of yield increase with fertilization level, the average data obtained for the three varieties were analyzed using a linear regression model. The results indicated a positive relationship between the application of phased fertilization and yield values per hectare. The coefficient of determination ($R^2 = 0.58$) showed that approximately 58% of the yield variation can be explained by the administered fertilization level. This suggests a significant influence of the fertilization regime on crop performance, even under the challenging climatic conditions of the 2023–2024 agricultural year.

It is important to note that this analysis is indicative, as it was based on data obtained from a single experimental plot for each treatment. The absence of multiple biological replicates limits the full statistical validity of the model. Nevertheless, the trend illustrated supports the descriptive observations and is consistent with the results of the other agro-productive analyses conducted in this study.

Figure 6 – Regression graph between fertilization level and thousand kernel weight (TKW)

The grain quality of wheat was evaluated based on three essential parameters: protein content, wet gluten content, and hectoliter weight (HW). These indicators directly reflect the influence of the applied technological regime and climatic conditions on the baking characteristics of the harvest.

Protein content varied both between varieties and between fertilization variants. Katarina showed the most stable and highest values, ranging between 12.5% and 13.8%, demonstrating superior protein accumulation even under moderate drought conditions. Apache showed a slight decrease in protein content in the control variant (below 12%), suggesting greater sensitivity to the lack of nutritional input. Biharia presented greater variability, with values ranging from 12.1% to 14.3%, indicating better fertilizer use efficiency but also a stronger reaction to fluctuations in moisture and temperature during grain filling.

Wet gluten content, an essential indicator of baking quality, followed a similar pattern to protein content. Katarina was in the superior category, with values between 27.5% and 28.8%, showing stable gluten quality under water stress. Biharia had high values, between 28.6% and 32.3%,

but with greater variation between variants, suggesting a complex interaction between nitrogen supply and climatic conditions. In contrast, Apache showed a reduction in gluten content, especially in the control variant (23.7%–24.5%), confirming the negative impact of nutrient deficiency on gluten protein quality.

Figure 7 – Regression graph between fertilization level and yield per hectare

Hectoliter weight (HW), an indicator of grain filling and commercial quality, recorded values above the minimum threshold (76 kg/hl) for all varieties, with the best results for Katarina (79–81 kg/hl). For Biharia, values ranged between 76–79 kg/hl, while for Apache, the control variant slightly dropped below 76 kg/hl, suggesting incomplete grain filling and greater sensitivity to nutrient and moisture deficiencies.

To provide a synthetic and comparative overview of the performance of the three varieties regarding grain quality, the maximum values obtained for protein content, wet gluten content, and hectoliter weight (HW) were graphically represented (Figure 8).

The graph highlights the superiority of Katarina in terms of stability and high values of hectoliter weight (81 kg/hl) and protein content (13.8%), demonstrating excellent adaptability to moderate drought conditions and the applied fertilization technology. Biharia recorded the highest values for wet gluten content (32.3%), indicating excellent baking quality but showed greater variability in the other parameters. Apache had the lowest maximum values, especially for hectoliter weight (76 kg/hl) and gluten (24.5%), which can be explained by its higher sensitivity to the lack of additional fertilization.

Figure 8 – Graph of the main grain quality indices: protein, wet gluten, and hectoliter weight

CONCLUSIONS

The research conducted at Denagro Martrans, in Gălbinași, Buzău County, during the 2023–2024 agricultural year, aimed to evaluate the agronomic and quality performance of three winter wheat varieties (Katarina, Biharia, Apache) grown under rainfed conditions, in restrictive climatic conditions characterized by severe precipitation deficits and elevated average temperatures.

The results demonstrated a significant influence of the fertilization regime on most of the analyzed parameters. Regarding spike density at harvest, phased fertilization applied in two and three stages led to a significant increase of this indicator, statistically confirmed by ANOVA analysis ($p < 0.0001$). Additional nitrogen application promoted both secondary tillering and reduced plant mortality during the vegetation cycle, resulting in a more uniform and efficient crop architecture.

The thousand kernel weight (TKW), an essential indicator for grain quality, was strongly influenced by fertilization, as shown by the statistical analysis ($p = 0.0014$) and the strong correlation obtained by regression analysis ($R^2 = 0.69$). Split fertilization contributed to improved grain filling and the achievement of higher quality yields, despite unfavorable pedoclimatic conditions.

Although the statistical analysis of yield per hectare did not show significant differences ($p = 0.22$), descriptive data indicated a clear trend of yield increase with increasing fertilization levels. Linear regression showed a positive relationship between fertilization level and yield ($R^2 = 0.58$). Katarina recorded the highest yields, reaching 7,711.4 kg/ha with three fertilizations, followed by Biharia and Apache, highlighting the importance of judicious fertilizer application in maximizing genetic potential.

Grain quality analysis revealed specific differences between varieties. Katarina stood out for its superior stability in protein content (12.5–13.8%) and high hectoliter weight (79–81 kg/hl). Biharia had a high wet gluten content (28.6–32.3%), indicating superior baking quality, but with slightly higher internal variability. Apache, although characterized by good drought tolerance, recorded the lowest values for all quality parameters in the control variant, confirming its higher sensitivity to the absence of additional fertilization.

In conclusion, the study confirmed that adaptation and intensification of phased fertilization can partially compensate for the negative effects of water stress on winter wheat crops, contributing both to yield improvement and grain quality enhancement. These results provide a solid basis for technological recommendations for farmers practicing agriculture under pedoclimatic conditions similar to those of the Gălbinași area and the southeastern regions of Romania.

ABSTRACT

Achillea millefolium L. (Asteraceae), commonly referred to as yarrow, is a medicinal plant with extensive ethnopharmacological use and increasing scientific interest due to its diverse phytochemical profile and broad-spectrum bioactivity. This review evaluates the current literature on the phytoconstituents, pharmacological properties, cosmetic applications, nutraceutical potential, toxicological considerations, and commercial viability of *A. millefolium*, with emphasis on its integration into contemporary dermatological formulations. The plant is characterized by a rich composition of bioactive compounds, including flavonoids such as apigenin, luteolin, quercetin, phenolic acids (chlorogenic acid, caffeic acid), sesquiterpene lactones (achillin, millefolide), and volatile constituents (camphor, borneol, linalool, cineole). These metabolites exhibit significant antioxidant, anti-inflammatory, antimicrobial, and cytoprotective activities, as demonstrated in both in vitro and in vivo models. In cosmetic science, *A. millefolium* extracts have shown efficacy in mitigating oxidative stress, modulating inflammatory pathways, enhancing wound healing, and inhibiting melanogenesis via tyrosinase suppression, thereby supporting their use in anti-aging and depigmenting formulations. In the nutraceutical domain, *A. millefolium* demonstrates therapeutic potential in gastrointestinal modulation, hepatoprotection, and glycemic control. Preclinical studies suggest its utility in managing metabolic syndrome and inflammatory conditions, although clinical trials remain limited. Toxicological assessments conducted by regulatory bodies, including the Cosmetic Ingredient Review (CIR) and European Medicines Agency (EMA), affirm its safety within defined concentration thresholds, with caution advised for individuals with Asteraceae sensitivities and during pregnancy. The plant's favorable regulatory status, sustainable cultivation profile, and multifunctional bioactivity underscore its commercial relevance. Future research should prioritize phytochemical standardization, advanced delivery systems, and translational studies to substantiate its efficacy and optimize its application in integrated cosmetic-nutraceutical formulations. This review consolidates the scientific foundation for *A. millefolium* as a promising candidate in evidence-based natural product development.

Keywords : *Achillea millefolium*, phytochemicals, nutraceuticals, dermatology, safety assessment,

INTRODUCTION

Achillea millefolium L., commonly referred to as yarrow, is a perennial species within the Asteraceae family, renowned for its longstanding role in traditional healing systems across diverse cultures. Historical records trace its medicinal use back over 3,000 years, with applications documented in ancient European, Asian, and Indigenous North American practices (Bashir et al., 2022). Traditionally, yarrow has been employed to treat wounds, gastrointestinal ailments, and inflammatory conditions (Strzępek-Gomółka et al., 2021). The genus name “*Achillea*” is derived from the legendary Greek warrior Achilles, who, according to myth, used the herb to tend battlefield injuries—underscoring its historical association with trauma care and anti-inflammatory effects (Singh et al., 2025). In Chinese herbal medicine, yarrow is valued for its ability to stimulate circulation, while European folk remedies favor its use in teas and poultices for digestive and dermal support (Jangjoo et al., 2023). Ethnobotanical documentation from Native American communities highlights its analgesic and antiseptic properties, particularly in treating minor wounds, insect stings, and bruises (Kachura, 2018). The resurgence of interest in plant-based therapeutics has propelled *A. millefolium* from a folkloric remedy to a scientifically endorsed botanical, driven by consumer preference for natural alternatives and growing pharmacological evidence supporting its efficacy (Barda et al., 2021). Yarrow is now widely incorporated into both topical skincare products and internal wellness supplements, owing to its antioxidant, antimicrobial, anti-inflammatory, and skin-regenerating effects (Gaweł-Bęben et al., 2020). These qualities make it a versatile ingredient in formulations ranging from anti-aging cosmetics to herbal infusions within the nutraceutical sector. Regulatory endorsements from institutions such as the European Medicines Agency (EMA) and the Cosmetic Ingredient Review (CIR) panel further validate its safety and functional potential (EMA, 2016; Becker et al., 2016). Phytochemically, *A. millefolium* is rich in bioactive constituents, including flavonoids like luteolin and apigenin, phenolic acids such as chlorogenic and rosmarinic acid, terpenes, sesquiterpene lactones, and essential oils (Konarska et al., 2025; Mihaylova, 2015). These compounds are responsible for its therapeutic actions, including modulation of inflammatory pathways, reduction of oxidative stress, and promotion of tissue regeneration (Farasati Far et al., 2023). Emerging clinical evidence supports its use in managing conditions such as dysmenorrhea, irritable bowel syndrome, and metabolic dysfunctions (Daneshvar-Ghahfarokhi et al., 2025; Moradi et al., 2023). Recent innovations in extraction and delivery technologies have enhanced the efficiency and stability of yarrow-derived compounds. Techniques such as ultrasound-assisted extraction (UAE), microwave-assisted extraction (MAE), and supercritical fluid extraction have improved phytochemical yield and integrity (Trendafilova & Todorova, 2008). Additionally, encapsulation strategies—including nanoliposomes, chitosan-based nanocarriers, and complex coacervation—have optimized bioavailability and targeted delivery, particularly in dermatological and pharmaceutical contexts (Nateghi et al., 2022; Székely-Szentmiklósi et al., 2024). This review seeks to consolidate contemporary research on *Achillea millefolium*, bridging its ethnobotanical legacy with modern pharmacological findings. It will examine the plant’s chemical composition, mechanisms of action, therapeutic relevance, safety profile, commercial applications, and avenues for future investigation.

METHODOLOGY

This review was conducted using a structured, multi-phase approach to synthesize current scientific literature on *Achillea millefolium* L. and its applications in nutraceutical and cosmetic science. Articles published between 2015 and 2025 were retrieved from databases including PubMed, Scopus, Web of Science, and ScienceDirect using keywords such as “*Achillea millefolium*,” “yarrow,” “phytochemistry,” “cosmetic applications,” “nutraceuticals,” “mechanism of action,” and “clinical trials.” Inclusion criteria focused on studies that provided experimental, clinical, or ethnobotanical data relevant to the plant’s bioactive compounds, pharmacological mechanisms, safety profile, and formulation technologies. Data extraction emphasized phytochemical composition, validated bioactivities, and technological advancements in extraction and delivery systems. Studies were categorized by application domain (nutraceutical, cosmetic, pharmacological) and evaluated for methodological rigor, sample size, and reproducibility. Ethnobotanical sources and regulatory documents were also reviewed to contextualize traditional uses and safety standards. Qualitative synthesis was used to identify trends, gaps, and future research directions.

RESULTS AND DISCUSSION

The literature review revealed consistent evidence supporting the multifunctional bioactivity of *Achillea millefolium*. Across selected studies, the plant demonstrated potent antioxidant activity validated by TEAC, FRAP, and CUPRAC assays, with phenolic acids and flavonoids identified as key contributors. Anti-inflammatory effects were confirmed through both in vitro and in vivo models, showing inhibition of COX enzymes and downregulation of NF- κ B and MAPK pathways. Cosmetic applications were supported by studies showing tyrosinase and elastase inhibition, enhanced fibroblast activity, and improved skin elasticity. Hydro glycolic and ethanolic extracts were found effective in anti-aging formulations, with SPF values and collagen-regulating properties documented in UVA-induced photoaging models. Clinical trials reported significant improvements in wound healing, menstrual pain, and gastrointestinal symptoms, aligning with traditional uses. Advanced extraction methods such as supercritical fluid extraction and microwave-assisted extraction improved phytochemical yield and stability. Encapsulation technologies-including nanoliposomes and PEG-based hydrogels-enhanced bioavailability and controlled release. Safety assessments confirmed low cytotoxicity and minimal adverse reactions, with regulatory recognition from EMA and CosIng databases.

Phytochemical Profile and Mechanism of Action

Achillea millefolium L. exhibits a complex and therapeutically significant phytochemical profile, especially within its aerial parts such as leaves and flowers, which contain a diverse array of bioactive compounds including essential oils, flavonoids, phenolic acids, sesquiterpene lactones, guaianolides, triterpenoids, and phytosterols (Konarska et al., 2023; Michalak et al., 2025). The essential oil fraction, typically obtained via hydro distillation, is rich in monoterpenes like β -pinene, sabinene, 1,8-cineole, camphor, linalool, and borneol, alongside sesquiterpenes such as chamazulene

and caryophyllene, which contribute to the plant's antimicrobial, anti-inflammatory, and antispasmodic properties (Gawel-Beben et al., 2020; Székely-Szentmiklósi et al., 2024). Polar extracts derived from hydroalcoholic and hydroglycolic solvents contain flavonoids including apigenin, luteolin, quercetin, and rutin—primarily in glycosylated forms—that exhibit potent antioxidant activity through reactive oxygen species scavenging and enhancement of endogenous enzymatic defenses (Villalva et al., 2022; Yeltay et al., 2025). Additionally, phenolic acids such as chlorogenic, caffeic, rosmarinic and dicaffeoylquinic acids reinforce the plant's antioxidant and antimicrobial profile while supporting hepatoprotective and cytoprotective functions (Ivanović et al., 2022; Tripon et al., 2024). Lipophilic constituents like achillin and leucodin, classified as sesquiterpene lactones and guaianolides, are known to inhibit inflammatory pathways including NF- κ B and MAPK and modulate cytokine production, enhancing their relevance in both systemic and topical applications (Farasati et al., 2023). Furthermore, triterpenoids and phytosterols such as β -sitosterol and taraxasterol derivatives contribute to skin barrier reinforcement, anti-aging effects, and inflammation modulation, making them valuable ingredients in modern cosmetic formulations (Michalak et al., 2025). The diverse bioactivities of *Achillea millefolium* stem from the synergistic interactions among its rich array of phytochemicals, including phenolic acids, flavonoids, sesquiterpene lactones, triterpenes, lignans, and essential oils. These compounds act on multiple molecular targets, contributing to the plant's antioxidant, anti-inflammatory, antimicrobial, antispasmodic, and skin-regenerative effects, which collectively support its integration into nutraceutical and cosmetic formulations. Antioxidant properties of *A. millefolium* have been extensively validated through assays such as Trolox Equivalent Antioxidant Capacity (TEAC), Ferric Reducing Antioxidant Power (FRAP), and Cupric Ion Reducing Antioxidant Capacity (CUPRAC). These confirm that phenolic acids like chlorogenic acid and flavonoids such as luteolin and apigenin effectively neutralize reactive oxygen species (ROS), thereby mitigating oxidative stress at the cellular level (Raudone et al., 2024; Marengo et al., 2025). This antioxidant activity is particularly relevant in dermatological applications, where ROS-induced damage contributes to photoaging, collagen degradation, and loss of skin elasticity. The anti-inflammatory effects of *A. millefolium* are mediated through inhibition of cyclooxygenase (COX) enzymes, attenuation of pro-inflammatory cytokines such as interleukin-6 (IL-6) and tumor necrosis factor-alpha (TNF- α), and downregulation of nuclear factor kappa B (NF- κ B) and mitogen-activated protein kinase (MAPK) signaling pathways (Saadat et al., 2024; Ali et al., 2017). These mechanisms underpin its efficacy in managing inflammatory skin conditions, menstrual pain, and systemic inflammatory disorders, as demonstrated in both experimental and clinical studies.

In addition to its anti-inflammatory and antioxidant roles, *A. millefolium* exhibits targeted enzymatic inhibition relevant to cosmetic applications. Its extracts have been shown to inhibit tyrosinase activity, a key enzyme in melanin biosynthesis, offering potential skin-lightening effects in formulations designed to treat hyperpigmentation and uneven skin tone (Raudone et al., 2024; Marengo et al., 2025). The modulation of melanogenesis is further supported by its influence on oxidative stress-related signaling pathways, including c-Jun N-terminal kinase (JNK) and extracellular signal-regulated kinase (ERK), which are implicated in pigmentation and cellular apoptosis. The plant's antispasmodic properties are primarily linked to its inhibitory effects on calcium channels, which regulate smooth muscle contraction. By modulating intracellular calcium influx, *A.*

millefolium induces tracheal and gastrointestinal muscle relaxation, offering therapeutic potential in conditions such as dysmenorrhea and irritable bowel syndrome (Ali et al., 2017; Barda et al., 2021). These effects are complemented by its gastroprotective actions, including mucosal healing and reduction of inflammation in the gastrointestinal tract. Moreover, *A. millefolium* demonstrates broad-spectrum antimicrobial activity against pathogens such as *Helicobacter pylori*, *Staphylococcus aureus*, and various fungal species. Essential oils and phenolic compounds disrupt microbial cell membranes and inhibit biofilm formation, enhancing its utility in topical formulations for acne, wound care, and oral hygiene (Ali et al., 2017; Barda et al., 2021). These properties are particularly valuable in cosmetic products aimed at maintaining skin barrier integrity and preventing microbial colonization. Collectively, these mechanisms highlight the therapeutic and cosmetic relevance of *Achillea millefolium*, providing a scientifically grounded rationale for its use in formulations designed to combat oxidative stress, inflammation, and microbial infections.

Nutraceutical Application

Achillea millefolium L., commonly known as yarrow, has demonstrated extensive nutraceutical potential supported by both traditional use and contemporary clinical research. Its gastrointestinal benefits are well established, with aqueous and alcoholic extracts showing antispasmodic, prokinetic, and antiulcer activities that contribute to improved recovery in conditions such as gastritis and irritable bowel syndrome (Salehi et al., 2020; Jangjoo et al., 2023). These effects are linked to its ability to reduce pro-inflammatory mediators, confirming its traditional role in soothing digestive inflammation (Ali et al., 2017; Akbar, 2020). Beyond digestive health, *A. millefolium* exhibits antidiabetic properties, including reductions in blood glucose, lipid profiles, and liver enzyme levels in diabetic models, largely attributed to its antioxidant-rich polyphenolic compounds that mitigate oxidative stress (Jangjoo et al., 2023). Its systemic effects extend into oncological applications, where in vitro studies have shown cytotoxic activity against breast, prostate, and gastric cancer cell lines through mechanisms involving apoptosis and cell cycle arrest, mediated by flavonoids and sesquiterpene lactones (Konarska et al., 2023; Barda et al., 2021). Some evidence suggests synergistic effects when combined with conventional chemotherapeutic agents. Neuromodulator and immune functions have also been observed, with clinical trials indicating anxiolytic and cognitive-enhancing effects, particularly when *A. millefolium* is used in combination with botanicals such as *Boswellia carterii* and *Zingiber officinale* (Salehi et al., 2020). These effects may be mediated through GABAergic modulation and antioxidant signaling pathways, while its immunomodulatory activity supports enhanced immune function via anti-inflammatory mechanisms (Barda et al., 2021; Farasati Far et al., 2023). In the domain of reproductive health, clinical trials have confirmed its efficacy in alleviating menstrual pain and dysmenorrhea, reinforcing its spasmolytic and anti-inflammatory properties as a natural alternative for managing primary dysmenorrhea (Raudone et al., 2024; Barda et al., 2021). Altogether, these findings highlight *A. millefolium* as a multifunctional botanical with validated applications in nutraceutical formulations targeting gastrointestinal, metabolic, oncological, neurological, immunological, and reproductive health.

Cosmetic Applications and Technological Advancements of *Achillea millefolium*

Achillea millefolium has emerged as a valuable botanical in cosmetic science, largely due to its potent antioxidant, anti-inflammatory, and regenerative effects that support skin renewal, wound healing, and microbial defense. Research indicates that its extracts promote fibroblast activity and stimulate collagen synthesis-key processes for preserving skin elasticity and minimizing the appearance of wrinkles (Akbar, 2020). Hydro glycolic formulations containing yarrow have shown measurable improvements in skin elasticity, collagen regeneration, and photoprotection, alongside inhibition of tyrosinase, a key enzyme in melanin synthesis (Gawel-Beben et al., 2020). Its ability to inhibit elastase and tyrosinase at low concentrations further supports its use in anti-aging and pigmentation-targeted treatments (Marengo et al., 2025). Experimental models simulating UVA-induced photoaging reveal that yarrow extracts help regulate collagen turnover and reduce cell death in dermal fibroblasts. Essential oil constituents such as linalyl acetate have been shown to influence melanogenesis through modulation of JNK and ERK signaling pathways (Marengo et al., 2025). Antioxidant evaluations using TEAC, FRAP, and CUPRAC assays demonstrate efficacy comparable to kojic acid, and ethanolic extracts have been successfully incorporated into peel-off gel masks for topical use (Strzpek-Gomółka et al., 2021). Variability in phytochemical composition across different morphotypes and growing conditions highlights the importance of standardized cultivation and sourcing practices (Raudone et al., 2024). In clinical contexts, *A. millefolium* has shown promise in wound care, exhibiting antimicrobial, anti-inflammatory, and tissue-repairing properties. These effects have been observed in applications such as episiotomy wound treatment, where reductions in pain, swelling, and erythema were reported (Salehi et al., 2020; Ali et al., 2017; Hajhashemi et al., 2018). The underlying mechanisms involve modulation of cytokine activity and enhancement of cellular repair processes (Barda et al., 2021; Ali et al., 2017). Its antioxidant capacity also contributes to mitigating oxidative stress, further supporting skin recovery. Ethnobotanical traditions that used yarrow for skin inflammation and wound healing are now substantiated by clinical evidence, including reduced skin reactions in patients undergoing radiotherapy (Jangjoo et al., 2023). Toxicological assessments affirm its safety for topical use (Ali et al., 2017; Marengo et al., 2025).

Recognized by the European Pharmacopoeia as a standardized herbal material, *A. millefolium* is widely formulated into creams, gels, and ointments for skin regeneration (Konarska et al., 2023). Its skin-conditioning and antimicrobial properties are linked to its ability to inhibit tyrosinase and neutralize reactive oxygen species, offering protection against environmental stressors such as UV radiation and pollution (Marengo et al., 2025; Konarska et al., 2023; Strzpek-Gomółka et al., 2021; Raudone et al., 2024). Its inclusion in the EU CosIng database further validates its regulatory acceptance and widespread use in moisturizers, anti-inflammatory products, and wound care formulations (Marengo et al., 2025). Recent innovations in extraction and delivery systems have significantly enhanced the stability and efficacy of yarrow-derived bio actives. Supercritical anti-solvent fractionation has proven effective in selectively concentrating key phenolic constituents of *Achillea millefolium*, including luteolin-7-O-glucoside and apigenin-7-O-glucoside. This method has been associated with a marked increase in antioxidant capacity and a higher concentration of anti-

inflammatory compounds such as camphor and borneol (Villalva et al., 2019; Villalva et al., 2022). Advances in nano emulsion technology have further enhanced the antimicrobial efficacy of yarrow extracts, improving droplet uniformity and colloidal stability. Gas chromatography–mass spectrometry (GC-MS) has identified a diverse profile of 51 volatile compounds, while zeta potential measurements confirm the structural integrity of the emulsions (Abu Safe et al., 2023). Additionally, hydro glycolic extraction using polyethylene glycol (PEG)-based systems has demonstrated strong preservation of polyphenols like caffeoylquinic acid and axillarin. These extracts exhibit notable sun protection factor (SPF) values and effective tyrosinase inhibition, making them highly suitable for incorporation into cosmetic formulations (Gaweł-Bęben et al., 2020). These advanced techniques facilitate better retention of volatile oils and polyphenolic compounds, improving topical delivery and bioavailability. Controlled-release formulations—such as ethosomal gels and PEG-based hydrogels—ensure that active ingredient concentrations remain within safe and effective ranges, minimizing adverse effects while maximizing therapeutic benefits (Andleeb et al., 2021; Czech et al., 2023).

Safety Profile: Preclinical and Clinical Evidence

Extensive safety assessments of *Achillea millefolium* have been conducted across multiple research platforms, including cellular assays, animal toxicology studies, and human dermatological trials. Laboratory-based in vitro analyses consistently reveal that yarrow extracts, when used at conventional concentrations, exhibit minimal cytotoxicity and do not trigger mutagenic or chromosomal damage. Investigations involving human lymphocytes and rodent bone marrow cells have further substantiated its non-genotoxic nature, supporting its safe incorporation into both topical and ingestible health products (Becker et al., 2016; Ali et al., 2017). Clinical dermatology studies reinforce its favorable safety profile. Cosmetic formulations containing less than 0.04% *A. millefolium* have undergone Human Repeated Insult Patch Testing (HRIPT), demonstrating negligible irritation or allergic reactions—even among individuals with sensitive skin conditions such as eczema or atopic dermatitis (Farasati Far, Behzad, & Khalili, 2023; Becker et al., 2016). These outcomes are further validated by advanced tissue-engineered models, including three-dimensional human corneal constructs, which confirm the extract's compatibility with delicate epithelial tissues (Strzępek-Gomółka, Gaweł-Bęben, & Kukula-Koch, 2021). In vivo toxicological studies using rodent models have established a high safety margin, with oral LD50 values surpassing 2000 mg/kg. This suggests a low likelihood of systemic toxicity under standard therapeutic or cosmetic use (Ali et al., 2017; Marengo et al., 2025). These findings support its use in nutraceuticals aimed at enhancing systemic health, particularly due to its antioxidant, anti-inflammatory, and hepatoprotective properties.

Adverse Reactions and Usage Precautions

While *A. millefolium* is generally well tolerated, certain constituents require cautious handling. Thujone, a monoterpene present in its essential oil, has shown neurotoxic and carcinogenic effects in high-dose animal studies, necessitating strict regulation of its concentration in oral supplements and aromatherapeutic products (Becker et al., 2016; Raudone et al., 2024). Additionally, compounds such as linalool and α -peroxyachifolid have demonstrated sensitization potential in dermal models,

although adverse reactions are rare at the low concentrations typically used in cosmetic applications (Becker et al., 2016; Strzępek-Gomółka et al., 2021). Occupational exposure to dried yarrow—particularly in agricultural or manufacturing settings—has been linked to allergic contact dermatitis, rhinitis, and respiratory symptoms including asthma. These cases underscore the need for protective measures and post-market surveillance to safeguard workers handling raw plant materials (Strzępek-Gomółka et al., 2021; Marengo et al., 2025). Regulatory frameworks, such as those outlined in the EU Cosmetic Ingredient Database (CosIng), recommend conservative usage thresholds: typically, below 0.04% in leave-on products and 0.03% in rinse-off formulations. These limits are based on toxicological evaluations and ensure consumer safety while preserving the therapeutic benefits of *A. millefolium* in skin care applications (Farasati Far et al., 2023; Becker et al., 2016).

Extraction, Formulation, and Quality Control

The extraction method plays a crucial role in determining the phytochemical composition and biological efficacy of *Achillea millefolium* products. Techniques such as supercritical fluid extraction and supercritical anti-solvent fractionation have been shown to preserve volatile compounds and concentrate bioactive constituents, thereby enhancing antioxidant, anti-inflammatory, and antimicrobial properties relevant to both nutraceutical and cosmetic applications (Salehi et al., 2020; Strzępek-Gomółka et al., 2021; Villalva et al., 2022). Hydro glycolic extraction, using water and polyethylene glycol, has also been optimized to yield stable formulations rich in chlorogenic acid and flavonoids, which exhibit strong tyrosinase-inhibitory and antioxidative activities suitable for skin care products (Gaweł-Bęben et al., 2020; Jangjoo et al., 2023a). These advanced extraction methods contribute to improved product performance and ensure batch-to-batch consistency, which is essential for regulatory compliance and consumer safety (Konarska et al., 2023). researchers have developed encapsulation systems such as nano emulsions, liposomes, and polymeric nanoparticles to enhance the stability and bioavailability of *A. millefolium*'s active compounds. These delivery platforms protect sensitive phytochemicals from degradation, improve dermal absorption, and enable controlled release for topical and oral applications (Salehi et al., 2020; Zangfirescu et al., 2020). Such innovations are particularly effective in addressing the volatility and hydrophobicity of certain compounds, thereby expanding the potential for high-performance cosmeceuticals and nutraceuticals (Villalva et al., 2022). Given the natural variability in plant morphology, cultivation conditions, and seasonal factors, standardization of *A. millefolium* extracts is essential. Analytical techniques such as high-performance liquid chromatography (HPLC) and metabolomic profiling are employed to quantify key biomarkers including chlorogenic acid, apigenin, and sesquiterpene lactones, ensuring consistency and reproducibility across batches (Strzępek-Gomółka et al., 2021)

Table 1: Major Phytochemical Classes in *Achillea millefolium* and Their Biological Functions

Phytochemical Class	Representative Compounds	Extraction Method	Key Biological Activities
Essential Oils	β -pinene, sabinene, 1,8-cineole, camphor, linalool, borneol	Hydrodistillation	Antimicrobial, anti-inflammatory, spasmolytic, skin penetration enhancer
Sesquiterpenes	Chamazulene, caryophyllene	Hydrodistillation	Antioxidant, anti-inflammatory, soothing effects
Flavonoids	Apigenin, luteolin, quercetin, rutin	Hydroalcoholic, hydroglycolic extraction	ROS scavenging, anti-aging, UV protection, collagen synthesis stimulation
Phenolic Acids	Chlorogenic, caffeic, rosmarinic, dicaffeoylquinic acids	Hydroalcoholic, PEG-based hydroglycolic	Antioxidant, antimicrobial, hepatoprotective, anti-inflammatory
Sesquiterpene Lactones	Achillin, leucodin	Lipophilic solvent extraction	NF- κ B and MAPK inhibition, cytokine modulation, cytotoxicity
Triterpenoids	Taraxasterol derivatives	Ethanol-based extraction	Skin barrier repair, anti-aging, emollient, anti-inflammatory
Phytosterols	β -sitosterol	Ethanol-based extraction	Anti-inflammatory, skin regeneration, barrier enhancement

These quality control measures are critical for guaranteeing clinical efficacy and safety in final products. The therapeutic potential of *Achillea millefolium*, encompassing its antioxidant, antimicrobial, wound-healing, and cytotoxic activities, has been substantiated through both experimental research and clinical evaluations, reinforcing its suitability for formulations aimed at treating skin inflammation, combating oxidative stress, and promoting tissue regeneration (Jangjoo et al., 2023; Konarska et al., 2023; Salehi et al., 2020; Strzpek-Gomółka et al., 2021). Traditional preparations such as oil macerates and alcoholic extracts have long been used for treating wounds and sunburn, and modern cosmetic products now incorporate enriched extracts or purified compounds to meet growing consumer demand for natural, multifunctional skin care solutions. Further investigation using human subjects and advanced 3D skin models is advised to validate the long-term safety of *Achillea millefolium* and refine its formulation approaches, despite its overall favorable safety profile (Strzpek-Gomółka et al., 2021). All the findings are shown in table 1.

CONCLUSION

Achillea millefolium exemplifies the successful evolution of a traditional medicinal plant into a scientifically validated ingredient for modern nutraceutical and cosmetic applications. Its rich phytochemical composition-including flavonoids, phenolic acids, terpenes, and essential oils-confers a broad spectrum of bioactivities such as antioxidants, anti-inflammatory, antimicrobial, wound-healing, and cytotoxic effects (Garcia-Oliveira et al., 2021; Jangjoo et al., 2023; Konarska et al., 2023). These properties support its use in managing gastrointestinal disorders, metabolic imbalances, dysmenorrhea, and skin conditions ranging from inflammation to aging (Salehi et al., 2020; Strzpek-Gomółka et al., 2021; Barda et al., 2021). Technological advancements have significantly enhanced the therapeutic potential of *A. millefolium*. Supercritical anti-solvent fractionation and nanoencapsulation techniques have improved the stability, bioavailability, and targeted delivery of its bioactive compounds, including luteolin-7-O-glucoside, camphor, and borneol (Villalva et al., 2022; Abu Safe et al., 2023). PEG-based hydroglycolic systems have preserved key polyphenols like caffeoylquinic acid and axillarin, boosting SPF and tyrosinase inhibition in topical formulations (Gaweł-Bęben et al., 2020). These innovations have expanded its commercial viability, particularly in cosmeceuticals targeting skin regeneration, pigmentation control, and protection against environmental stressors (Strzpek-Gomółka et al., 2021; Marengo et al., 2025). Despite its favorable safety profile, further validation through human clinical trials and advanced 3D skin models is recommended to confirm long-term tolerability and optimize formulation strategies (Becker et al., 2016; Strzpek-Gomółka et al., 2021). Regulatory harmonization remains essential, especially for international distribution, with *A. millefolium* already listed in the EU CosIng database and widely used in consumer products (Marengo et al., 2025; European Medicines Agency, 2020). Safety assessments indicate low toxicity at standard concentrations, though certain constituents like thujone and hydroquinone warrant careful formulation oversight (Becker et al., 2016). The literature from the last decade consistently reinforces *A. millefolium*'s multifunctional applications. Its antioxidant and antimicrobial properties support its inclusion in skin care products aimed at preventing oxidative damage and microbial infections, while its cytotoxic and immunomodulatory effects suggest potential roles in cancer chemoprevention and immune support (Jangjoo et al., 2023; Tripon et al., 2024; Ali et al., 2017). Comparative Phyto profiling studies further highlight the importance of morphotype and organ-specific extract selection to optimize therapeutic outcomes (Raudone et al., 2024). Looking ahead, future research should focus on dose-finding clinical trials, mechanistic studies, and long-term safety evaluations across diverse populations. Mapping chemotypes and morphotypes data to pharmacological activities will be crucial for standardizing extract quality and maximizing efficacy (Raudone et al., 2024; Salehi et al., 2020). Additionally, exploring novel formulations tailored to specific consumer needs-such as anti-aging, skin repair, or metabolic support-will expand its market potential (Jangjoo et al., 2023). In conclusion, *Achillea millefolium* stands out as a versatile botanical resource with scientifically supported bioactivities that align with both traditional use and modern therapeutic demands. Its integration into nutraceuticals and cosmetics reflects a growing preference for natural, multifunctional ingredients. Continued interdisciplinary research and regulatory

refinement will be key to unlocking its full potential in health and wellness innovation (Barda et al., 2021).

ABSTRACT

The present study aimed to evaluate the agronomic behavior and qualitative performance of three winter wheat varieties (Katarina, Biharia, Apache) cultivated under rainfed conditions in the pedoclimatic context of Gălbinași, Buzău County, Romania, during the 2023–2024 agricultural year. The experiment was carried out on a 45 ha experimental field and applied a conventional cultivation technology including soil tillage and phased fertilization, tested in three variants: control (no additional fertilization), two-phase fertilization, and three-phase fertilization. Data collection included plant density at emergence and harvest, thousand-kernel weight, number of grains per spike, test weight, yield per hectare, and grain quality indices (moisture, protein content, wet gluten content). Statistical analysis (ANOVA and linear regression) demonstrated the significant influence of fertilization on plant density and kernel weight ($p < 0.05$), with a moderate correlation between fertilization level and yield ($R^2 = 0.58$). The variety Katarina recorded the highest stability and yield potential (7711.4 kg/ha with three-phase fertilization), followed by Biharia and Apache. Grain quality was superior for Katarina and Biharia regarding protein and gluten content, while Apache showed lower values under low fertilization. The results highlight the potential of phased nitrogen fertilization to mitigate drought stress effects and improve both yield and grain quality under the restrictive climatic conditions of southeastern Romania. The study provides valuable recommendations for optimizing winter wheat cultivation technologies in areas with similar pedoclimatic conditions.

Keywords: soil tillage, fertilization, wheat, drought, climate change

INTRODUCTION

Agriculture is one of the oldest human occupations, emerging with the transition from nomadism to sedentary living (Guş & Tianu, 1991). Throughout the evolution of human societies, agriculture has diversified and improved, being strongly influenced by technological and social progress. A defining moment was the invention of the plough, evolving from simple wooden beams

to modern ploughs with mechanical traction and multiple moldboards (Panaiteescu, 2016; Panaiteescu & Niță, 2011). The expansion of mechanization, the use of chemical fertilizers, and the introduction of genetic engineering have significantly increased yields but have also generated negative environmental impacts (Budoï & Penescu, 1996; Cakpo et al., 2025).

In Romania, studies by the National Research and Development Institute for Soil Science, Agrochemistry and Environmental Protection have highlighted the degradation of soil quality through erosion, acidification, salinization, compaction, and chemical pollution (Patriche et al., 2023a; Patriche et al., 2023b; Stănilă, 2023). Globally, the intensification of conventional agricultural practices has contributed to biodiversity loss, water pollution, and contamination of agri-food products (Gagiu et al., 2023; Gagiu et al., 2025). Therefore, adapting these practices is essential to protect ecosystems and human health (Budoï & Penescu, 1996; Calistru et al., 2024).

In recent decades, climate change has become a major challenge for global agriculture. The global average temperature has increased by approximately 1.7°C compared to the pre-industrial period and is projected to rise by up to 2.7°C in the coming decades (Bandoc & Prăvălie, 2015; Moise, 2023; European Environment Agency, 2023). In temperate continental regions, such as Muntenia, these changes translate into prolonged droughts, uneven precipitation distribution, heatwaves, torrential rains, hail, and extreme winds (Niță et al., 2024; European Environment Agency, 2023). The Gălbinași commune, Buzău County, frequently faces such phenomena, requiring the adaptation of agricultural technologies to the new conditions (Gagiu et al., 2025).

Winter wheat (*Triticum aestivum* L.) remains one of the key crops in Romania due to its economic value and its ability to adapt to local soil and climate conditions (Panaiteescu, 2016; Popescu et al., 2023). The choice of suitable variety, the application of adapted cultivation technologies, and soil conservation are key factors in achieving stable and high-quality yields (Guş & Tianu, 1991; Cakpo et al., 2025).

The aim of this study is to analyze the behavior and suitability of three winter wheat varieties grown under non-irrigated conditions in Gălbinași, Buzău County, during the 2023–2024 agricultural year, characterized by extreme climatic conditions. The applied cultivation technology was conventional, including soil tillage (Cakpo et al., 2025), and phased fertilization varied depending on variety and treatment (Calistru et al., 2024). For each variety, three experimental variants were tested: control (no additional phased fertilization), two-stage phased fertilization, and three-stage phased fertilization.

The specific objectives of the study are: to compare the agronomic behavior of the three wheat varieties under identical technological and climatic conditions; to analyze the performance of the varieties under conventional systems in terms of agronomic efficiency and conservation of soil and water resources, within the context of sustainable agriculture; to formulate technical recommendations on variety selection and cultivation technology adapted to the specific conditions of Gălbinași, with the possibility of extending the results to areas with similar pedoclimatic conditions; to reduce production costs and achieve high and superior quality yields.

MATERIAL AND METHOD

The study was conducted during the 2023–2024 agricultural year on a 45-hectare experimental plot belonging to Denagro Martrans company, located in Gălbinași, Buzău County, in a region representative of large-scale farming in southeastern Romania. The area's climate is excessively continental, characterized by hot, dry summers with maximum temperatures reaching 39°C, and cold winters with frequent blizzards and temperatures dropping below -20°C. Annual precipitation is low and unevenly distributed, while the average annual temperature is around 11.5°C. The soils in the

experimental area are classified as cambic chernozems, with a loamy texture in the upper horizon and loamy-silty texture in intermediate horizons, developed on calcareous loess deposits, and with a physical structure suitable for conventional agricultural practices.

The biological material consisted of three winter wheat (*Triticum aestivum* L.) varieties: Apache, Katarina, and Biharia. Apache is an early, awnless variety with medium height, excellent lodging resistance, high tillering and winter hardiness, and good tolerance to foliar diseases, particularly rusts and fusarium. Katarina, also early and awnless, has strong emergence vigor, good winter hardiness, high yield potential, and resistance to major diseases. Biharia is a semi-late variety, with short stature and short awns, notable for its drought, lodging, and disease resistance, as well as for its very good tillering capacity.

The cultivation technology followed conventional system principles, including primary ploughing, soil loosening and leveling, followed by sowing at a 12.5 cm row spacing with the same seeding rate for all experimental variants. The experiment comprised nine variants, three for each variety, organized as follows: a control variant (without additional phased fertilization, to highlight the biological potential and the effect of the previous crop), a variant with two-stage phased fertilization, and a variant with three-stage phased fertilization. Plant protection treatments (herbicides, fungicides, and insecticides) were uniformly applied across all variants, ensuring that the observed differences could be attributed exclusively to the genotypes and fertilization regime.

To evaluate the agro-productive performance of the three varieties, observations and measurements were carried out throughout the growing season. These included plant density at emergence and harvest (expressed as plants/m²), thousand kernel weight (TKW), determined by weighing a standardized sample of mature grains, number of grains per spike, determined by manual harvest and counting, hectoliter weight expressed in kg/hl according to SR 13574:2010 standard, and average yield per hectare, calculated based on the weight of grains relative to the cultivated area. Additionally, grain quality parameters (moisture, protein, and gluten content) were analyzed using appropriate laboratory equipment.

To analyze differences among the experimental variants and assess the influence of fertilization under the water stress conditions characteristic of the study year, the data were subjected to statistical analysis. Analysis of variance (ANOVA) was used to test the significance of differences between treatments, and linear regression models were applied to evaluate the relationship between fertilization level, yield, and lack of precipitation. The significance level was set at $p \leq 0.05$. Data processing was performed using SPSS statistical software (version 26) and Microsoft Excel.

RESULTS AND DISCUSSION

In the experiment, soil preparation for the winter wheat crop followed agrotechnical principles aimed at maximizing the productive potential of the crop. Winter wheat performs best when preceded by early-harvest species that leave the soil rich in nitrogen and other essential nutrients, thereby enabling timely execution of primary soil work. In all nine experimental variants, the preceding crop was pea, a legume highly valued agronomically due to its ability to fix atmospheric nitrogen and leave the soil weed-free, enriched with plant residues that, once incorporated, increase organic matter content and stimulate soil microbiological activity.

The experiment was conducted on a total area of 45 hectares, equally divided among the three tested wheat varieties: Apache, Katarina, and Biharia. Each variety was cultivated on 15 hectares, further split into three experimental variants of 5 hectares each: control (without additional fertilization), two-stage phased fertilization, and three-stage phased fertilization.

For the control variant, the crop relied solely on residual nitrogen and nutrients left in the soil after the pea crop, to assess the biological potential of the varieties without the influence of additional fertilization. In the fertilized variants, the first application coincided with sowing in the first decade of October, with 300 kg/ha of Duofertil Eurocereal 34 (N, P, S) from Timac, a product designed to mobilize and protect nutrients and stimulate root development thanks to the Mappa Duo and XCK complex. The second application, applied to both the two- and three-stage fertilization variants, took place on March 18, using Sulfammo 25 Mappa Duo at a rate of 150 kg/ha, a solid fertilizer with 25% nitrogen and 31% sulfur trioxide. The three-stage fertilization variant also received an additional foliar treatment on April 28, at flag leaf emergence, applying 30 l/ha of In-Folen (19% nitrogen, 5% magnesium oxide, 10% sulfur trioxide), aimed at enhancing enzymatic activity and optimizing grain quality parameters.

Soil preparation included deep ploughing at approximately 25 cm depth in the second decade of August, using a Lemken EurOpal 5 plough, with the purpose of turning over the furrow, incorporating plant residues, and ensuring good soil aeration and loosening. The ploughing depth was adjusted according to the soil's moisture level and the amount of plant residue.

Figure 1 – Fertilization scheme of the three winter wheat varieties across experimental variants

The climatic conditions recorded during the growing season were characterized by positive temperature anomalies and a significant precipitation deficit, which increased the importance of the applied technology and fertilization regime. The climatic data recorded in the experimental area are presented in figure 2. Monthly average temperatures were significantly higher than the multiannual normal, with notable differences in December 2023 and January 2024, where temperatures exceeded the normal values by approximately 5°C.

Regarding precipitation, the total amount accumulated during the 2023–2024 agricultural year was 311.4 mm, which is 114.4 mm below the multiannual average (425.8 mm). Severe water deficits were recorded especially during the active growing months (March–June), with a total of 116.7 mm compared to the estimated requirement of 280–320 mm for optimal wheat development at this stage. Only January and April recorded values above the normal average, but the surplus was insignificant.

Figure 2 – Evolution of precipitation and temperatures in the study area, Gălbinași locality, during the 2023–2024 agricultural year

Seedbed preparation was carried out on October 4, 2023, with a single pass of the Vaderstad TopDown 400 cultivator, which broke down the plough furrows, loosened, and leveled the soil to facilitate optimal seed-to-soil contact. The seeds used came from certified seed lots (C1 biological category), with a physical purity of 99.80% for Biharia and Katarina and 98.70% for Apache, and a germination capacity of 97%. The thousand kernel weight (TKW) was 42 g for Biharia and Katarina, and 40 g for Apache.

Before sowing, the seeds were mandatorily treated with Austral Plus (500 ml/100 kg seed), a broad-spectrum insecto-fungicide. Sowing took place on October 6, 2023, at a row spacing of 12.5 cm and a sowing depth of 4 cm, with a seeding rate of 390 germinable seeds/m², corresponding to approximately 210 kg seed/ha.

Weed control was achieved through integrated preventive methods and chemical treatments. The main weeds identified were *Sinapis arvensis*, *Cirsium arvense*, *Centaurea cyanus*, *Chenopodium album*, *Galium aparine*, *Capsella bursa-pastoris* (dicotyledonous species), and *Avena fatua*, *Poa annua* (monocotyledonous species). Control of monocotyledonous weeds was achieved with Starane Super (0.4 l/ha), applied on April 24 together with insecto-fungicides. Dicotyledonous weeds were controlled with Biathlon 4D (0.07 kg/ha) and adjuvant Dash HC (1 l/ha), applied at the 6–8 leaf stage on May 11.

Plant protection against diseases was carried out in two stages: the first treatment with Evolus (1 l/ha) on April 24, and the second with Falcon Pro (0.9 l/ha) on May 11, providing preventive, curative, and eradicated protection. Pest control was initially ensured by seed treatment, followed by two chemical treatments: Lamdex Extra (0.3 kg/ha, April 24) and Delmetros 100SC (0.15 l/ha, May 11).

Harvesting was performed on June 28, 2024, with a Deutz Fahr C7206 combine equipped with a cereal header. The grain moisture at harvest ranged between 11.5% and 12.6%. After threshing, the straw was baled, and the grain was transported and stored in designated facilities.

The yield results showed a clear influence of the fertilization regime and variety used. The average yields obtained were: for Katarina, 7,711.4 kg/ha (three fertilizations), 6,425.1 kg/ha (two fertilizations), and 5,689.6 kg/ha (control); for Biharia, 6,543.6 kg/ha (three fertilizations), 5,689.6

kg/ha (two fertilizations), and 4,615.4 kg/ha (control); for Apache, 6,108.7 kg/ha (three fertilizations), 4,848.4 kg/ha (two fertilizations), and 3,365.4 kg/ha (control). These results confirm the benefits of split nitrogen application, especially under challenging climatic conditions and significant water deficits.

Plant density at emergence was determined using standardized methods by counting plants per linear meter over 10 rows with three repetitions for each experimental variant at the first true leaf stage. The average values show a positive influence of fertilization on final crop density.

For Katarina, the average plant density for the three-fertilization variant was 308 plants/m² (min. 27, max. 34 plants), for two fertilizations 302 plants/m² (min. 27, max. 33 plants), and for the control 288 plants/m² (min. 26, max. 34 plants). For Biharia, the values were 305 plants/m² (three fertilizations), 300 plants/m² (two fertilizations), and 283 plants/m² (control), with individual ranges between 26 and 34 plants/m². For Apache, densities were 300 plants/m² (three fertilizations), 299 plants/m² (two fertilizations), and 276 plants/m² (control), ranging from 26 to 33 plants/m².

The results show a clear tendency for increased plant density as fertilization intensity increased across all three varieties. This is attributed to improved germination vigor and seedling emergence, resulting from the additional nutrient (mainly nitrogen) supply applied at sowing. The data also indicate good emergence uniformity, with consistent values between repetitions, highlighting seed quality and effective seedbed preparation.

Spike density at harvest was determined by counting spikes per linear meter over 10 rows, with three repetitions for each variety and fertilization variant. The average values showed a clear influence of fertilization on spike density, demonstrating the positive effect of nitrogen supplementation on tillering capacity and plant survival up to harvest.

For Katarina, spike density was 567 spikes/m² (three fertilizations), 531 spikes/m² (two fertilizations), and 508 spikes/m² (control). For Biharia, values were 532 spikes/m² (three fertilizations), 508 spikes/m² (two fertilizations), and 491 spikes/m² (control). For Apache, values were 509 spikes/m² (three fertilizations), 480 spikes/m² (two fertilizations), and 474 spikes/m² (control). The observed minimum–maximum ranges per row were 44–62 spikes for Katarina, 42–61 spikes for Biharia, and 40–62 spikes for Apache, confirming moderate variability but with a clear tendency for increased spike density with increased fertilization.

These results support the hypothesis that split fertilizer application leads to higher final plant densities at harvest, due to reduced plant mortality and stimulated secondary tillering during the growing season.

To validate the significance of the differences between experimental variants for spike density at harvest, raw data (10 repetitions per variant) were subjected to analysis of variance (ANOVA). The ANOVA test showed extremely significant differences between varieties and fertilization variants ($F(2,87) = 12.28$; $p < 0.0001$). These data confirm that the fertilization regime had a strong impact on spike density at harvest, mainly by stimulating secondary tillering and reducing plant mortality under the severe water deficit conditions recorded in the 2023–2024 agricultural year. A directly proportional relationship between increased fertilization intensity and spike density was consistently observed across all three studied varieties.

The results confirm the hypothesis that split nitrogen application, adapted to wheat phenological stages, optimizes crop architecture and contributes to yield stability under challenging climatic conditions.

To provide a detailed representation of experimental data variability, spike density at harvest was also illustrated using a boxplot diagram (Figure 3). This enabled visualization of the full distribution of the 10 repetitions for each variety and fertilization variant. The boxplot highlights medians, interquartile ranges, and potential outliers, providing a comprehensive picture of result

consistency. A clear trend of higher average density for Katarina, followed by Biharia and Apache, was observed, in line with the previously calculated averages. Slightly higher variability for Biharia was noted, possibly due to greater sensitivity to water stress conditions.

Figure 3 – Boxplot of spike density distribution at harvest for the three wheat varieties

To better understand the relationship between fertilization level and final spike density at harvest, the average data obtained for the three varieties were subjected to linear regression analysis. Fertilization was coded ordinally (0 = control, 1 = two fertilizations, 2 = three fertilizations). The regression model revealed a positive relationship between increasing fertilization intensity and final spike density. The resulting regression line indicated a clear trend of increased crop density with additional fertilizer application. The coefficient of determination ($R^2 = 0.45$) suggests that approximately 45% of the variation in spike density at harvest can be attributed to differences in the applied fertilization regimes.

This result supports the conclusions of the ANOVA test and confirms the hypothesis that phased fertilization, adapted to the phenological requirements of the crop, significantly contributes to reducing plant mortality and stimulating secondary tillering, thereby optimizing crop architecture under water stress conditions.

Figure 4 – Regression between fertilization level and spike density at harvest

The determination of the thousand kernel weight (TKW) was carried out by repeated weighing of samples taken from all experimental variants, in order to identify the influence of the fertilization regime on this essential quality indicator. The results showed a clear tendency for TKW to increase with the intensification of fertilization for all three varieties studied. For Katarina, the average values were 44 g (three fertilizations), 42 g (two fertilizations), and 40 g (control). For Biharia, values were 44 g (three fertilizations), 40 g (two fertilizations), and 35 g (control). For Apache, the values were 43 g, 39 g, and 31 g, respectively.

To validate the statistical significance of the differences, raw data were subjected to ANOVA testing. The analysis revealed significant differences between varieties and variants ($F(2,60) = 7.35$; $p = 0.0014$). These results demonstrate the strong influence of split fertilizer application on thousand kernel weight, particularly under the difficult pedoclimatic conditions of the 2023–2024 agricultural year, characterized by precipitation deficit and water stress. It can be concluded that judicious application of nitrogen fertilization, aligned with crop phenological stages, optimizes the grain filling process and contributes to achieving superior grain quality.

To provide a detailed characterization of data variability from the determination of thousand kernel weight (TKW), a visual analysis was performed using a boxplot (Figure 5). This representation highlighted the distribution of values obtained for the three studied varieties: Katarina, Biharia, and Apache. The boxplot reveals clear differences between the three genotypes, with Katarina showing the lowest internal variability, which may indicate superior stability of this trait under unfavorable pedoclimatic conditions. In contrast, Biharia and Apache showed greater dispersion of values, suggesting a stronger reaction to abiotic stress or interaction with the applied fertilization technology.

Distribution of thousand kernel weight (TKW) for the three wheat varieties

Figure 5 – Boxplot of thousand kernel weight (TKW) distribution for the three wheat varieties

To quantify the relationship between fertilization level and thousand kernel weight (TKW), a linear regression model was applied to the average values obtained for the three varieties and the three fertilization regimes. The results indicated a positive relationship between increased fertilization intensity and higher TKW values. The regression analysis produced a coefficient of determination (R^2) of 0.69, meaning that approximately 69% of the variation in thousand kernel weight can be explained by the applied fertilization level. This demonstrates a strong and predictable influence of the nutritional regime on grain quality. The results are fully consistent with those highlighted by the ANOVA test and the boxplot analysis, further supporting the hypothesis that phased fertilization, adapted to the specific requirements of the crop, plays a decisive role in improving the quality parameters of the wheat harvest.

Figure 6 – Regression graph between fertilization level and thousand kernel weight (TKW)

The yield per hectare was determined based on the harvest obtained for each variety and experimental variant. The results showed a clear trend of yield increase with the intensification of the fertilization regime.

For the Katarina variety, yields of 7,711.4 kg/ha (three fertilizations), 6,425.1 kg/ha (two fertilizations), and 5,689.6 kg/ha (control) were recorded. For Biharia, yields were 6,543.6 kg/ha (three fertilizations), 5,689.6 kg/ha (two fertilizations), and 4,615.4 kg/ha (control). For Apache, values of 6,108.7 kg/ha, 4,848.4 kg/ha, and 3,365.4 kg/ha were recorded for the same variants.

To test the significance of the differences between varieties and fertilization variants, an analysis of variance (ANOVA) was applied. Although notable value differences were observed, the statistical test indicated a lack of statistical significance ($F(2,6) = 1.96$; $p = 0.22$). This is explained by the absence of multiple biological replicates for each variant, as the data were obtained from a single experimental plot per treatment. Therefore, these results must be interpreted primarily descriptively, without rigorous statistical validation. Nevertheless, the clear trend of increased yield with increasing fertilization level is evident and correlates with the other agro-productive data previously analyzed (spike density at harvest, number of grains per spike, thousand kernel weight), confirming the effectiveness of phased fertilization even under the difficult climatic conditions of the 2023–2024 agricultural year.

To highlight the trend of yield increase with fertilization level, the average data obtained for the three varieties were analyzed using a linear regression model. The results indicated a positive relationship between the application of phased fertilization and yield values per hectare. The coefficient of determination ($R^2 = 0.58$) showed that approximately 58% of the yield variation can be explained by the administered fertilization level. This suggests a significant influence of the fertilization regime on crop performance, even under the challenging climatic conditions of the 2023–2024 agricultural year.

It is important to note that this analysis is indicative, as it was based on data obtained from a single experimental plot for each treatment. The absence of multiple biological replicates limits the full statistical validity of the model. Nevertheless, the trend illustrated supports the descriptive

observations and is consistent with the results of the other agro-productive analyses conducted in this study.

Figure 7 – Regression graph between fertilization level and yield per hectare

The grain quality of wheat was evaluated based on three essential parameters: protein content, wet gluten content, and hectoliter weight (HW). These indicators directly reflect the influence of the applied technological regime and climatic conditions on the baking characteristics of the harvest.

Protein content varied both between varieties and between fertilization variants. Katarina showed the most stable and highest values, ranging between 12.5% and 13.8%, demonstrating superior protein accumulation even under moderate drought conditions. Apache showed a slight decrease in protein content in the control variant (below 12%), suggesting greater sensitivity to the lack of nutritional input. Biharia presented greater variability, with values ranging from 12.1% to 14.3%, indicating better fertilizer use efficiency but also a stronger reaction to fluctuations in moisture and temperature during grain filling.

Wet gluten content, an essential indicator of baking quality, followed a similar pattern to protein content. Katarina was in the superior category, with values between 27.5% and 28.8%, showing stable gluten quality under water stress. Biharia had high values, between 28.6% and 32.3%, but with greater variation between variants, suggesting a complex interaction between nitrogen supply and climatic conditions. In contrast, Apache showed a reduction in gluten content, especially in the control variant (23.7%–24.5%), confirming the negative impact of nutrient deficiency on gluten protein quality.

Hectoliter weight (HW), an indicator of grain filling and commercial quality, recorded values above the minimum threshold (76 kg/hl) for all varieties, with the best results for Katarina (79–81 kg/hl). For Biharia, values ranged between 76–79 kg/hl, while for Apache, the control variant slightly dropped below 76 kg/hl, suggesting incomplete grain filling and greater sensitivity to nutrient and moisture deficiencies.

To provide a synthetic and comparative overview of the performance of the three varieties regarding grain quality, the maximum values obtained for protein content, wet gluten content, and hectoliter weight (HW) were graphically represented (Figure 8).

The graph highlights the superiority of Katarina in terms of stability and high values of hectoliter weight (81 kg/hl) and protein content (13.8%), demonstrating excellent adaptability to moderate drought conditions and the applied fertilization technology. Biharia recorded the highest values for wet gluten content (32.3%), indicating excellent baking quality but showed greater variability in the other parameters. Apache had the lowest maximum values, especially for hectoliter weight (76 kg/hl) and gluten (24.5%), which can be explained by its higher sensitivity to the lack of additional fertilization.

Figure 8 – Graph of the main grain quality indices: protein, wet gluten, and hectoliter weight

CONCLUSIONS

The research conducted at Denagro Martrans, in Gălbinași, Buzău County, during the 2023–2024 agricultural year, aimed to evaluate the agronomic and quality performance of three winter wheat varieties (Katarina, Biharia, Apache) grown under rainfed conditions, in restrictive climatic conditions characterized by severe precipitation deficits and elevated average temperatures.

The results demonstrated a significant influence of the fertilization regime on most of the analyzed parameters. Regarding spike density at harvest, phased fertilization applied in two and three stages led to a significant increase of this indicator, statistically confirmed by ANOVA analysis ($p < 0.0001$). Additional nitrogen application promoted both secondary tillering and reduced plant mortality during the vegetation cycle, resulting in a more uniform and efficient crop architecture.

The thousand kernel weight (TKW), an essential indicator for grain quality, was strongly influenced by fertilization, as shown by the statistical analysis ($p = 0.0014$) and the strong correlation obtained by regression analysis ($R^2 = 0.69$). Split fertilization contributed to improved grain filling and the achievement of higher quality yields, despite unfavorable pedoclimatic conditions.

Although the statistical analysis of yield per hectare did not show significant differences ($p = 0.22$), descriptive data indicated a clear trend of yield increase with increasing fertilization levels. Linear regression showed a positive relationship between fertilization level and yield ($R^2 = 0.58$). Katarina recorded the highest yields, reaching 7,711.4 kg/ha with three fertilizations, followed by Biharia and Apache, highlighting the importance of judicious fertilizer application in maximizing genetic potential.

Grain quality analysis revealed specific differences between varieties. Katarina stood out for its superior stability in protein content (12.5–13.8%) and high hectoliter weight (79–81 kg/hl). Biharia had a high wet gluten content (28.6–32.3%), indicating superior baking quality, but with slightly higher internal variability. Apache, although characterized by good drought tolerance, recorded the lowest values for all quality parameters in the control variant, confirming its higher sensitivity to the absence of additional fertilization.

In conclusion, the study confirmed that adaptation and intensification of phased fertilization can partially compensate for the negative effects of water stress on winter wheat crops, contributing both to yield improvement and grain quality enhancement. These results provide a solid basis for technological recommendations for farmers practicing agriculture under pedoclimatic conditions similar to those of the Gălbinași area and the southeastern regions of Romania.

ABSTRACT

Persimmon (*Diospyros kaki* L.), originally from China and widely cultivated throughout East Asia, has recently gained popularity in several Mediterranean countries, including Türkiye. This study was conducted to determine the optimum harvest time by evaluating the biochemical and aromatic changes in persimmons at different maturity stages. The research was carried out in a commercial orchard in the Dareski hamlet of the Toroslar district, Mersin Province, focusing on the commonly grown 'Hachia' cultivar. Fruits were harvested at seven-day intervals beginning in the last week of October and analyzed at two distinct maturity stages: unripe and fully ripe. Sugar analysis revealed that glucose and fructose were the predominant sugars in both stages, with significantly higher levels in ripe fruits (8930 and 9166 mg/100g, respectively) compared to unripe ones (6561 and 7213 mg/100g). Total sugar content increased from 13,867 to 18,248 mg/100g, along with an increase in total soluble solid content (TSS) from 14.45% to 19.4%. In terms of organic acids, malic acid was dominant in unripe fruits (22.43 mg/100g), whereas succinic acid significantly increased in ripe fruits (38.27 mg/100g). Citric and ascorbic acid contents also varied notably between the two stages, and titratable acidity rose from 0.86% to 1.14% during ripening. Volatile compound profiling revealed clear maturity-dependent differences. Aldehyde compounds were more abundant in ripe fruits (37.76%), contributing to a richer and more intense aroma, while alcohols and terpenes predominated in unripe fruits (17.44% and 44.98%, respectively), with linalool, nerol, and limonene as major contributors. These findings confirm that the biochemical and aromatic profiles of persimmons are strongly influenced by the maturity stage, which has important implications for flavor development, postharvest quality, and market value. Despite increasing interest among consumers and producers, persimmon production in Türkiye is still limited due to challenges in storage and marketing. The study suggests that harvesting after the second ripening stage may improve product quality and commercial potential under the Mediterranean climate of Mersin.

Keywords: Persimmon, maturity stage, sugars, organic acids, volatile compounds.

INTRODUCTION

Fruit cultivation worldwide is generally concentrated on a limited number of species; however, persimmon (*Diospyros kaki* L.), belonging to the Ebenaceae family, has gradually expanded to many regions of the world and has gained increasing popularity in recent decades (Öz and Özelkök, 2003). Native to China, persimmon was first extensively cultivated in Japan and later established in modern orchards in countries such as the United States (California), Italy, Brazil, New Zealand, Australia, and Israel (Kaynaş & Kuzucu, 2004). The fruit, known for its attractive appearance and pleasant taste, has been given names such as “Japanese persimmon,” “Mediterranean persimmon,” and “cennet hurması” in Turkey (Yıldız Akbulut, 2021). Although the genus *Diospyros* contains numerous species, only four

(*D. kaki* Thunb., *D. lotus* L., *D. virginiana* L., and *D. oleifera* Cheng) are of commercial importance, with *D. kaki* being the most widely cultivated for fresh consumption and processing (Kitagawa & Glucina, 1984; Yıldız et al., 2012). In Turkey, persimmon production has expanded considerably in the last 20–25 years. While production levels were between 15,000–20,000 tons in the early 2000s, it increased to 127,314 tons in 2023 and reached 142,584 tons in 2024, showing a 12% growth within a year (Anonymous, 2025a). This rise reflects both consumer demand and the fruit's adaptation to different climatic regions of Türkiye, including the Mediterranean, Aegean, Marmara, and Black Sea. Persimmons are harvested between September and December, displaying wide variation in fruit shape, size, and skin color. Both astringent and non-astringent cultivars are cultivated; while astringent fruits are unpleasantly bitter when unripe due to soluble tannins, they become sweet and palatable after softening or through specific postharvest treatments (Onur, 1990).

The ripening of persimmon fruit is a complex process involving physiological, biochemical, and structural changes. These changes affect sensory attributes such as color, taste, and texture, determining overall fruit quality (Chitarra et al., 2005). During maturation, chlorophyll degradation and carotenoid accumulation cause color changes from green to yellow, orange, or reddish hues (Kluge et al., 2018; Zhao et al., 2011). Studies have shown that carotenoid content, including lycopene, increases markedly during the mid to late stages of ripening, contributing to the reddish coloration of certain cultivars (Qi et al., 2019). Texture softening is mainly attributed to pectin degradation, cell wall disintegration, and membrane breakdown, while increased intercellular spaces and water loss lead to fruit weight reduction (Salvador et al., 2007; Tessmer et al., 2016; Sapper et al., 2019). Carbohydrate metabolism plays a key role in fruit ripening and sweetness perception. Changes in sugar composition are largely influenced by cultivar-specific enzymatic activity. In general, sucrose content decreases while glucose and fructose increase during ripening due to invertase activity (Bubba et al., 2009; Giordani et al., 2011; Santos et al., 2019). Different developmental patterns have been reported, such as sucrose reduction accompanied by increases in glucose and fructose or stability in certain sugars depending on the cultivar (Santos et al., 2018). Alongside carbohydrates, organic acids, amino acids, phenolics, and choline also undergo significant changes during maturation, especially in the late stages of development (Santos et al., 2018). Nutritionally, persimmon is an important source of ascorbic acid, carotenoids, phenolic compounds, and dietary fiber, contributing to high antioxidant activity and health-promoting effects (Parseker Yönel et al., 2008). Vitamins A and E, tannins, and minerals also enhance its nutritional and functional food value. These properties have contributed to growing consumer demand worldwide. However, challenges such as cultivar identification, determination of optimum harvest time, and effective postharvest handling still cause yield and quality losses (Onur, 1990; Tuzcu & Yıldırım, 2000). A major quality determinant is astringency, resulting from soluble tannins, which decrease during ripening due to polymerization or can be artificially reduced through treatments such as ethylene exposure, CO₂ application, or storage in alkaline solutions (Itoo, 1971; Itoo, 1980; Taira et al., 1997). Considering its nutritional richness, consumer preference, and economic potential, persimmon has become an increasingly valuable fruit crop in Turkey. Nevertheless, studies on its phytochemical and volatile composition under local ecological conditions are still limited. Therefore, this study focuses on the characterization of phytochemical compounds and volatile profiles of the 'Hachiya' persimmon cultivar grown under the ecological conditions of Mersin (Toroslar, Türkiye). The results are expected to provide new insights into ripening behavior, postharvest quality, and flavor development, ultimately contributing to reducing postharvest losses and increasing consumer acceptance.

MATERIALS AND METHODS

Plant Material

Persimmon fruit samples were collected from 20-year-old Hachiya trees planted in 5x5 spacings at various stages of ripening in a producer garden in Darseki village, Toroslar district, Mersin province. The samples were collected twice in 2023, once in October (unripe period) and once in November (ripe period). Fruit samples from three distinct trees and five fruit samples from different sides of the tree (North, South, West, and East) were taken in three repetitions during each harvest period and brought to the Horticulture laboratory of Çukurova University Faculty of Agriculture in an ice box cold chain. After washing the samples in tap water, 1 gram of hand squeezed fresh fruit juice was utilized for each biochemical assay.

Method

Total Soluble Solids (TSS): The SSC of representative fruit samples was measured as °Brix using a digital refractometer (Atago, Japan). A drop of fruit juice was placed on the screen, and the displayed value was recorded as % SSC.

Titrateable acidity (TA): A 1 ml sample of fruit juice was titrated with 0.1 N NaOH solution until the pH reached 8.1. The acidity was expressed as a percentage of malic acid (Cemeroğlu 2007).

Individual Sugar and Organic Acid Extraction and Determination

Sugars and organic acids were extracted individually following the procedure described by Mikulic-Petkovsek et al. (2016). Homogenized, unfrozen fruit samples were placed in a test tube containing 4 mL of bi-distilled water, at 1 g. The mixture was continuously mixed on a vortex mixer at room temperature for thirty minutes. After extraction, the samples were centrifuged at 9000 x g for ten minutes at 4°C to obtain the supernatant and then filtered into vials using cellulose membranes. The extracts were stored at -20°C for further investigation. The high-performance liquid chromatography (HPLC) system was equipped with a refractive index detector (Shimadzu RID 20A VP, Kyoto, Japan), an in-line degasser, a pump, a controller, and a 20 µL injection volume automatic injector. Chromatographic separation was performed using a reverse-phase Ultrasphere Coregel-87 C analytical column (300 mm × 7.8 mm i.d., 5 µm, Transgenomic) at a flow rate of 0.6 mL/min, heated to 70 °C, and with the mobile phase being ultrapure water. Data acquisition and processing were performed with Shimadzu Class VP chromatography management software (Kyoto, Japan). Concentrations of individual sugars are reported as percentages of fresh weight (FW) determined using original standards.

Volatile compounds were extracted by solid-phase microextraction (SPME)

Volatile compounds obtained from persimmon fruit were studied using three randomly selected fruits at each stage, both unripe and commercially ripe. For each case, 1 gram of homogenized seed tissue was placed in a headspace vial, and then 1 mL of CaCl₂ was added. Following a 30-minute 40 °C treatment, the volatile components were extracted using a solid-phase microextraction (SPME) fiber coated with CAR/PDMS (blue fiber). Using the method detailed by Polat and colleagues (2022), the obtained aroma compounds were then analyzed and quantified using a Shimadzu GC-2010 Plus gas chromatography-mass spectrometry (GC/MS) system.

Statistical Analyses

The experiment was performed with a completely randomised experimental block design in three replications two stages (unripe, ripe) in each replicate. Data were processed with the SPSS package

program version 23.0 (SPSS Inc., Chicago, IL, USA). All data were presented as the mean $\pm$ standard error (SE) and analyzed by one-way analysis of variance (ANOVA). (Steel, et al 1997).

RESULT AND DISCUSSION

Sugars are also related to the total soluble solids (TSS) content. In persimmon, this characteristic ranges from 12 to 22 °Brix, due to the great differences between cultivars, maturation, and postharvest treatments, which influence both the content and the profile of these compounds (Kluge et al., 2018). It is important to highlight that the presence of soluble tannins also influence the TSS content. Kim and Ko (1997) observed that astringent fruits with higher levels of soluble tannins presented more TSS than non-astringent cultivars did. When these soluble tannins are no longer present (after a precipitation treatment), the TSS content is affected and there is no clear difference between astringent and non-astringent cultivar types. Therefore, Tessmer et al (2016) suggest that TSS measurement should be used to identify the sugars level only in non-astringent cultivars.

At the ripe stage, the TSS (Total Soluble Solids) value was 19.4% and the titratable acidity was 1.14%, whereas at the unripe stage, the TSS value was 14.45% and the titratable acidity was 0.86% (Table 1; Figure 1). This characteristic positively reflects on the storage period by prolonging the fruit's shelf life. Accordingly, for fruits intended to be stored for longer durations, early harvests, especially those performed in November, are expected to provide significant advantages in terms of storage longevity. When previous studies are examined, it is evident that total soluble solids content (TSS) and titratable acidity (TA) values vary significantly depending on harvest time, cultivar, and ecological conditions. Özkan and Can (2013), in their study on the 'Hachiya' cultivar in Alaşehir (Manisa), reported TSS values of 14.47%, 18.06%, and 20.80% at the first, fourth, and sixth harvests, respectively. In the same study, TA values were determined as 0.19%, 0.16%, and 0.10% at the corresponding harvest times. Similarly, Kaynaş and Kuzucu (2004) reported SSC values of 23.84%, 23.65%, 22.65%, 22.75%, and 22.46% in persimmons harvested at five different times in the Çanakkale region. Yılmaz and Şeker (2024) found that SSC values ranged between 13.62% and 17.67%, being directly associated with harvest time. They noted that cultivars with astringent flesh generally had higher SSC values, such as 17.67% in 'Hachiya' and 15.72% in 'Rojo Brillante'. According to Mowat and Chee (2011), persimmons intended for export in New Zealand must meet industry class standards of an average SSC of 14% at harvest, with a minimum of 12%. In another study, Kılıç et al., (2022) reported SSC values between 18.05% and 20.63% in 'Hachiya', 'Rojo Brillante', 'Hana Fuyu', and 'Fuyu' cultivars grown in Denizli ecological conditions. TA values in the same study were determined to range between 0.14% and 0.28%. Üstün et al., (2017) also investigated different persimmon types and reported SSC values of 14.0–18.9%, total sugars of 12.3–17.1 mg/100 g, reducing sugars of 10.3–16.5 mg/100 g, sucrose of 0.38–1.90 mg/100 g, TA of 0.06–0.14%, and L-ascorbic acid content of 6.8–19.65 mg/100 g. In the study, the SSC was determined as 19.4% and the TA as 1.14% at the ripe stage, whereas at the unripe stage, the SSC was 14.45% and the TA was 0.86%. These findings are consistent with the results reported by Özkan and Can (2013), Yılmaz and Şeker (2013), Kaynaş and Kuzucu (2004), and Kılıç et al., (2022).

Table 1. Contents total soluble solids (TSS) and titratable acidity (TA) of persimmon fruit

	ripe persimmon	unripe persimmon
Total soluble solids	19.4 $\pm$ 0.10	14.45 $\pm$ 0.05
Titratable acidity	1.14 $\pm$ 0.04	0.86 $\pm$ 0.01

Figure 1. Contents total soluble solids (TSS) and titrateable acidity (TA) of persimmon fruit

Sugars

In study, four sugars glucose, fructose, sucrose, and xylose were analyzed and measured for each cultivar (Table 2). Glucose was identified as the predominant sugar, followed by fructose, sucrose, and xylose. As the fruit ripened, starch was enzymatically hydrolyzed into simple sugars such as glucose and fructose, leading to a noticeable increase in sugar content (Yılmaz, and Bostan 2024).

At the ripe stage, the highest level was observed in glucose (95.67 ± 0.15 mg/100 g), followed by fructose (91.66 ± 3.33 mg/100 g), sucrose (89.30 ± 2.30 mg/100 g), and xylose (55.40 ± 8.35 mg/100 g). The total sugar content at this stage was determined as 182.48 ± 7.17 mg/100 g.

At the unripe stage, glucose again showed the highest concentration (72.13 ± 0.08 mg/100 g), followed by fructose (53.42 ± 18.69 mg/100 g), sucrose (65.61 ± 0.76 mg/100 g), and xylose (38.96 ± 7.61 mg/100 g). The total sugar content in the unripe stage was found to be 138.67 ± 27.13 mg/100 g (Table 2; Figure 2). The results of the study suggest that when determining the harvest date of persimmon, it is important to consider when the fruit will be marketed after harvest. If the harvested fruits are intended for storage, the harvest should be carried out during the early stages of fruit development, which corresponds to the second week of November for the Toros region. If the fruits are to be marketed without storage, the harvest should be delayed to later stages; however, in this case, as the fruit approaches the end of the ripening process on the tree, it becomes more attractive in terms of color and taste, but also more susceptible to environmental factors, particularly bird damage. On the other hand, early autumn frosts that may occur in the region during this period can cause chilling injury in the fruits. Fruits harvested in the early stages of development (the first week of November) were found not to reach high-quality edible ripeness, and the astringency caused by tannins was not eliminated in fruits at the edible stage. Robert et al. (2010) reported glucose contents in persimmon ranging from 4.78 to 8.79 mg/100g, fructose from 3.80 to 7.78 mg/100g, and sucrose from 0.91 to 1.22 mg/100g. Similarly, Candir et al., (2009) found that, considering both individual and total sugar concentrations, the cultivar 'Tone Wase' had the highest glucose (8.79 mg/100g), fructose (7.78 mg/100g), and total sugar (17.8 mg/100g) contents. In a study on harvest maturity of persimmon, Gasanov et al., (1973) reported that sugar accumulation during ripening was higher in Khiakume and Tamopan cultivars compared to Tsuronoko and Zendzhimaru. They further noted that the total sugar content varied among cultivars depending on harvest stage, with the highest level found in Emon and the lowest in Tamopan. In the same study, tannin content was determined as 0.164 mg/100g in Khiakume and Zendzhimaru, and 0.083 mg/100g in Tsuronoko, Emon, and Tamopan cultivars. Glew

et al., (2005) demonstrated that the major sugars accumulated in persimmon juice were fructose and glucose, which increased up to 43.55 mg/100g FW and 35.45 mg/100g FW, respectively, during ripening. Sucrose remained relatively low and declined throughout ripening. These values were slightly lower than those reported by Daood et al. (1992) for an unidentified *D. kaki* L. cultivar, which contained higher glucose (11.0 mg/100g) and fructose (10.1 mg/100g) levels. The lowest total sugar content was measured in fully ripe 'O'Gosho', 'Cal Fuyu', and 'Hana Fuyu' cultivars, averaging 10.7 mg/100g. Sweetness is clearly one of the most important internal quality attributes and a key breeding objective in persimmon cultivation. Therefore, promoting cultivars with higher sugar contents is strongly emphasized. The total sugar content in persimmon is comparable to that in apples, which range between 11.5 and 18.3 mg/100g (Hofer et al., 2005). However, in apples, the predominant sugar is fructose, followed by glucose and sucrose (Veberic, Zadavec and Stampar, 2007). In persimmon cultivars with the highest total sugar concentrations, levels can reach 15–23 mg/100g, with glucose being the dominant sugar, followed by fructose and sucrose (Usenik, Fabcic and Stampar, 2008).

Table 2. Sugar content in the persimmon fruit (mg/100 g)

Sugars	Ripe persimmon	Unripe persimmon
Xylose	55.40±8.35	38.96±7.61
Sucrose	89.30±2.30	65.61±0.76
Glucose	95.67±0.15	72.13±0.08
Fructose	91.66±3.33	53.42±18.69
Total Sugar	182.48±7.17	138.67±27.13

Figure 2. Sugar content in the persimmon fruit

The glucose and fructose levels determined in our study, when compared with the ranges reported by Robert et al., (2010) and Candır et al., (2009) (glucose: 4.78–8.79 mg/100g; fructose: 3.80–7.78 mg/100g), were found. This indicates that varietal/genotypic differences and ecological conditions play a decisive role in sugar accumulation. Our findings, compared with the 15–23 mg/100g levels reported by Gasanov et al., (1973) and Usenik et al., (2008), were at high levels. This result demonstrates that fruit ripening stage and growing conditions have a strong effect on total sugar content. The sucrose levels obtained in our study were consistent with / deviated from the findings of Glew et al., (2005), who reported that sucrose remains relatively low and decreases during ripening.

Our findings show that, in terms of sweetness and internal quality characteristics, persimmon exhibits trends similar to those reported in the literature, although differences arise depending on cultivar, growing conditions, and ripening stage. It can be concluded that genotypes with higher sugar accumulation should be preferred in cultivation.

Organic acids

Organic acids play a critical role in defining fruit taste and regulating various physiological processes, with their composition largely dependent on the cultivar. The sugar–acid balance is one of the main determinants of flavor in fruits. In addition, organic acids contribute to nutrient digestion, stimulate blood circulation, and serve as important quality indicators. Their type and concentration vary among fruit species and generally decrease as ripening progresses (Kıralan and Gündoğdu, 2021).

In study, a natural decrease in organic acid content was observed in persimmon cultivars as ripening advanced. The contents of L-ascorbic acid, citric acid, and malic acid were determined in the cultivars, and the results are summarized in Table 5. Among these, succinic acid and malic acid were identified as the predominant organic acids.

The sweet taste of a fruit is important for its quality and sensorial acceptance, and both primary metabolites, sugars and organic acids, play an important role. It is estimated that a higher proportion between sugars and organic acids leads to a better perception of sweet taste. (Veberic et al., 2009; Santos et al., 2017). Malic acid exerts an important influence on the sensory characteristics of persimmon (Kluge, et al 2018) and, as identified by some authors, it is one of the main organic acids in this fruit, followed by citric acid and fumaric acids (Veberic et al., 2009; Santos et al., 2017; Ryu et al., 2016).

In ripe fruits, malic acid 18.23 ± 0.50 mg/100 g FW, citric acid 11.29 ± 0.77 mg/100 g FW, and L-ascorbic acid 8.09 ± 0.45 mg/100 g FW. The total organic acid content was determined as 37.62 ± 1.42 mg/100 g (Table 3; Figure 3). In unripe fruits, higher values were recorded: citric acid 10.02 ± 0.16 mg/100 g FW, malic acid 22.43 ± 0.79 mg/100 g FW, and L-ascorbic acid 6.94 ± 0.67 mg/100 g FW (Table 3; Figure 3). The total organic acid content of unripe fruits was calculated as 39.40 ± 0.54 mg/100 g. The observed reduction in total acidity during fruit ripening reflects the typical metabolic changes associated with maturation (Patel et al., 2019).

Robert et al., (2010) reported that the total organic acid content was 68.1 mg/100g in the cultivar ‘Jiro’, while in the cultivars ‘Triumph’ and ‘Tipo’ it was more than twice as high, averaging 14.39 mg/100 g of organic acids. Among the organic acids analyzed, the highest malic acid content was measured in the cultivar ‘Triumph’ (10.44 mg/100 g FW), whereas the lowest value was found in ‘Jiro’ (4.01 mg/100 g FW). The malic acid levels in all analyzed cultivars were considerably lower than those reported by Daood et al., (1992), who measured 35.45 mg/100 g FW in ripe fruit of an unidentified persimmon cultivar. Compared to sweet cherry, which contains 35.30–81.20 mg/100 g FW of malic acid (Usenik et al., 2008), the fully ripe fruits of the analyzed persimmon cultivars had much lower malic acid levels. The cultivars contained between 1.96 and 7.01 mg/100 g FW of citric acid, values comparable to those obtained by Daood et al., (1992), who reported 6.57 mg/100 g citric acid in ripe persimmon fruit. In comparison with apple, which contains between 5.20 and 70 mg/100 g FW of citric acid, persimmon is lower in citric acid content. Glew et al., (2005) demonstrated that the major organic acids in date plum fruit were citric and malic acids, which increased during the immature and mid-ripe stages and then decreased in overripe fruit. According to Usenik et al., (2008), ripe persimmon fruit is also rich in these organic acids. However, compared with elderberry, which contains on average 30.80–48.10 mg/100 g of citric acid (Veberic, Jakopic, Stampar and Schmitzer, 2008), persimmon has a significantly lower citric acid content. In other tropical fruits, such as papaya and pineapple, the concentration of citric acid in ripe fruit is much higher (Hernández, Lobo, &

González, 2008). This result is consistent with the low organic acid contents in persimmon reported by Robert et al., (2010) and Daood et al., (1992).

Table 3. Organic acids content in the persimmon fruit (mg/100 g)

	Ripe persimmon	Unripe persimmon
Citric Acid	11.29±0.77	10.02±0.16
Malic Acid	18.23±0.50	22.43±0.79
Ascorbic Acid	8.09±0.45	6.94±0.67
Total acid	37.62±1.42	39.40±0.54

Figure 3. Organic acids content in the persimmon fruit

Volatile Compounds

The volatile compounds identified in persimmon fruits are summarized in Figure 1. Using blue SPME, at the ripe stage the main volatile groups detected were total terpenes (10.39%), total esters (9.37%), total aldehydes (37.76%), total acids (37.08%), total ketones (2.32%), and total alcohols (3.38%)(Figure 4). A total of 31 individual components were identified in the juice, comprising four alcohols, nine aldehydes, one ester, nine acids, three ketones, and five terpenes. Among the extraction methods tested, blue SPME proved to be the most suitable for isolating volatile compounds from persimmon juice.

Aldehydes and acids were found to be the predominant volatile groups in persimmon fruits (Table 4). Key aldehydes detected included hexanal (25.16%), (E)-2-hexenal (2.69%), and trans-2,4-dodecadienal (2.63%), with notably higher levels in ripe fruits. Among acids, acetic acid (22.82%), nonanoic acid (2.62%), and hexanoic acid (2.07%) were the most abundant, also with higher levels in ripe fruits. Within the alcohol group, menthol (1.27%) and 1-octanol (0.82%) were prominent, particularly in ripe fruits. Esters such as 1,2-benzenedicarboxylic acid, diethyl ester (7.26%) were identified as important contributors to aroma and were highly abundant in ripe fruits. Esters are known to impart fruity and floral notes that play a critical role in cultivar differentiation. Regarding terpenes, benzene (isothiocyanatomethyl), benzene, 1-methyl-2-(1-methylethyl)-, and naphthalene, 1,6-

dimethyl-4-(1-methylethyl)- were the major compounds identified. Among them, benzene (isothiocyanatomethyl) was particularly abundant (6.52%) in ripe fruits (Table 4).

At the unripe stage, the main volatile groups detected were total terpenes (44.98%), total esters (1.39%), total aldehydes (10.23%), total acids (17.56%), total ketones (8.40%), and total alcohols (17.44%). A total of 27 individual compounds were identified in the juice, consisting of five alcohols, seven aldehydes, two esters, eight acids, three ketones, and four terpenes. Aldehydes and acids were again found to be the predominant volatile groups in persimmon fruits (Table 3). The key aldehydes detected included hydroxymethyl furfural (6.10%) and 2-furancarboxaldehyde (1.84%), both showing notably higher levels in unripe fruits. Among acids, acetic acid (5.29%), (E)-9-octadecenoic acid (5.10%), and pentadecanoic acid (4.81%) were prominent, also with higher abundance at the unripe stage. Within the alcohol group, linalool (7.10%), geraniol (3.76%), and nerol (3.48%) were prominent, particularly in ripe fruits. The major ketone identified was 2,3-dihydro-3,5-dihydroxy-6-methyl-4H-pyran-4-one (8.40%). Regarding terpenes, (+)-limonene (42.93%) was the dominant compound identified in unripe persimmon fruits. In the study, it was determined that with increasing ripeness, the amounts of aldehydes, esters, and acids increased, while the amounts of alcohols, ketones, and terpenes decreased. The results of the study revealed that the main factor responsible for changes in the aroma compounds of persimmon fruit was the progression of ripening over time. As the maturity index increased, the composition of aroma compounds also changed. Terpenes were found to increase up to a certain stage of ripening and then decrease in the later stages, with a higher number of terpene compounds identified in the unripe stage. Limonene was identified as the common terpene component in both cultivars.

In persimmon, the total alcohol content within the volatile compound profile decreased during ripening, whereas the proportion of ester compounds increased. In contrast, ketone levels showed a decreasing trend as ripening progressed. As fruits ripen, the quantity and quality of volatile compounds responsible for aroma increase, reaching their maximum at full maturity. The synthesis of aroma compounds is influenced not only by the genetic makeup but also by ecological factors, rootstock, cultivar, altitude, cumulative temperature during the growing season, ripening stage, and storage conditions. The source of aroma compounds largely comes from sugars, proteins, and fats metabolized during ripening. Therefore, aroma formation during ripening occurs not only through enzymatic synthesis but also through the breakdown and transformation of these metabolites. In other words, as the fruit ripens, volatile aroma compounds are primarily produced via metabolic degradation processes and enzyme activity (Perez et al., 1996; Kaynaş et al., 2022).

Besada et al., (2013) reported a high-resolution volatile profiling of fruits from 12 persimmon cultivars, identifying 67 compounds. This profiling was used to characterize the different astringency types of persimmon fruit before and after deastringency treatment. Fruits that do not naturally accumulate astringent compounds (PCNA type) exhibited high levels of 3(2H)-benzofuranone, whereas this compound was not detected in any astringent-type fruits (non-PCNA). In addition, at harvest, PCNA cultivars showed higher accumulation of benzeneacetaldehyde and lipid-derived aldehydes (hexanal, heptanal, octanal, and decanal) compared to non-PCNA fruits. Wang et al., (2012)

reported that gas chromatography–mass spectrometry (GC-MS) analysis of the extract led to the positive identification of 50 compounds, among which aldehydes emerged as the most important class of volatile compounds. Gas chromatography–olfactometry (GC-O) analysis of the aroma extract revealed that 32 compounds had an aroma impact. The six most intense aroma-impact compounds were methional, (E)-2-Hexenal, Phenylacetaldehyde, (E,Z)-2,6-Nonadienal, Hexanal, and Furaneol. The aroma qualities of these compounds largely explain the aroma profile of persimmon fruit, which was described as fresh peach, a touch of orange, sweet, woody, floral, green, and potato-like. The unambiguous identification of trace aroma-impact compounds – (E,E,Z)-2,4,6-Nonatrienal and (E,Z,Z)-2,4,7-Decatrienal – was achieved by applying a solid-phase extraction procedure for the selective isolation of carbonyl compounds using GC-MS.

CONCLUSION

The study observed a significant increase in TSS values and a decrease in titratable acidity (TEA) throughout the ripening process. Harvesting: For optimum quality, high TSS (18–20%) and low TEA (0.1–0.2%) values should be targeted at harvest. Therefore, producers are advised to pay attention not only to rind color but also to the sugar/acid balance. In terms of sugar composition, glucose and fructose levels increase with ripening, while sucrose levels gradually decrease. This can be explained by the high activity of the invertase enzyme (Bubba et al., 2009; Santos et al., 2019). Sugar-acid balance: Sweetness (high glucose + fructose) and low acidity (reduction of malic and citric acid) play important roles in consumer taste. Therefore, post-harvest ripening methods (CO₂, ethylene, limewater) should be used to improve flavor balance. In terms of organic acids, it has been observed that malic and citric acid levels gradually decrease during the ripening process, resulting in a decrease in acidity and an increase in sweetness perception. In terms of volatile compounds, aroma compounds, particularly aldehydes, esters, and furaneol, have been found to vary with ripening and contribute to the fruit's characteristic aroma (Wang et al., 2012; Besada et al., 2013). Storage conditions: Because persimmon is climacteric, low-temperature and controlled-atmosphere storage conditions are important for maintaining the sugar-acid balance in the fruit and preventing aroma loss. The Hachiya variety, with its high sugar and aroma profile, can be utilized in drying, juice, and functional food products to create value-added products. The TSS, TA individual sugars, organic acids, and aroma values obtained from the analyses were found to be at sufficient levels in the final harvest period in terms of fruit edibility. Detailed examination of sugar and organic acid metabolism in different genotypes, correlation with consumer taste, and monitoring of changes during storage are recommended.

ABSTRACT

Isparta province is a province where both continental and Mediterranean climates are experienced together, as it is located in the continental interior of the Mediterranean Region. So, winters are cold and summers are hot and dry. Geographically located in the lake region, this province has both mountains and flat areas. It is known that geographical conditions affect the spread of bee diseases and increase the incidence of bee losses. For this reason, researching beekeeping and bee diseases in Isparta province is very important. In this study, the first findings on the presence of Nosemosis in bee colonies in Isparta province are presented. Nosemosis was detected in two of the examined beehives. Five of the 194 live bee samples and four of the 180 dead bee samples were infected with nosema agents. The infection rate varies between 11.4% and 3.8%. The infection average is 2.4%. However, the number of sampled beehives needs to be increased to represent the entire Isparta region, other pathogens and parasites need to be investigated and each needs to be identified at the species level.

Keywords: Honey bee, Disease, Nosemosis, Isparta, Türkiye

INTRODUCTION

Beekeeping is rapidly increasing worldwide due to the diversity of bee product production. Türkiye has an important potential in beekeeping in terms of its rich plant diversity and suitable ecology. However, this wealth of natural resources is not being utilized sufficiently in Türkiye. The Aegean, Black Sea and Mediterranean regions of Türkiye are the most important regions for beekeeping in terms of both the number of hives and the share of production (Yıldız and Fakir 2019). Isparta province is located in the continental interior of the Mediterranean Region and experiences both continental and Mediterranean climates. So, winters are cold and summers are hot and dry. Geographically located in the lake region, this province has both mountains and flat areas. In addition, most of the beekeepers in Isparta province practice migratory beekeeping. In this case, it further increases the spread of bee diseases, causes stress in bees and increases the incidence of bee losses (Ratia, 2012). Additionally, Isparta has 36,924 colonies, 256 tons of honey production, and 6.92 kg/colony honey yield, ranking 60th in Türkiye's honey production (TÜİK, 2025). For this reason, researching beekeeping and bee diseases in Isparta province is very important. In this study, it was aimed to present the first findings to determine the current status of Nosemosis presence in bee colonies in Isparta province.

MATERIAL AND METHOD

Bee samples were collected from 5 apiaries in Isparta region. Total 374 adult bee samples, 180 dead and 194 living bees were provided in April and May 2025. After macroscopic examination, dead and living adult bees were dissected in Ringer's solution and wet smears were prepared. Host fat body, malpighian tubules, gut epithelium, and hemolymph were examined for the presence of pathogens under a light microscope at $\times 400$ –1000 magnification (Yaman et al. 2019). When an infection with the pathogen was observed, a part of the material was used for the preparation of Giemsa-stained smears. For this, the slides were air-dried and fixed with methanol, then stained with freshly prepared 5% solution of Giemsa stain and reexamined under the microscope by using the oil immersion lens. The spores detected by the light microscopy were measured and photographed using a microscope with a digital camera and Soft Imaging System (Yaman and Sağlam 2023; Yaman et al. 2023).

RESULTS AND DISCUSSION

In this study, the first findings were presented to determine the presence of Nosemosis, the most important harmful disease of honey bees, in bee colonies in Isparta province.

Spore of the pathogen is the most characteristic stage in the examined bees. Light microscopic examinations of the living and dead bees revealed the presence of the pathogen spores in the intestine and the body cavity. Signs of infection spores were confirmed using the Giemsa staining technique (Figure 1). Mature fresh and Giemsa stained spores were measured. Mature fresh spores measured $4.46 \pm 0.22 \times 2.53 \pm 0.21$ (n=25) and Giemsa stained spores $4.12 \pm 0.49 \times 2.33 \pm 0.21$ μm (n=25).

Figure 1. *Nosema* spp. Giemsa stained spores (1000X).

Nosemosis was observed in 9 of 374 adult worker bees examined in Isparta province, and the average infection rate was determined as 2.4% (Table 1). During the study, the disease was observed in two (3.15%) of the examined five localities in Isparta province. The highest nosemosis was determined in Central 5.6% rates respectively. Five of the 194 live bee samples examined and four of the 180 dead bee samples examined were infected with nosema agents. The infection rate ranged from 11.4% to 3.8%. Nosemosis detected in the city center was detected in a bee sample taken from a migratory beekeeper, while Nosemosis detected in the Gelendost district was detected in a bee sample taken from a stationary beekeeper.

Table 1. Table 1. Occurrence of Nosemosis in Isparta province, Türkiye.

Location	Living bee samples	Nosema	%	Dead bee samples	Nosema	%	Total
Centre	35	4	11,4	107	4	3,8	5.6
Isparta/ISUBÜ West Campus-1	33	-	0	8	-	0	-
Isparta/ISUBÜ West Campus-2	44	-	0	27	-	0	-
Aşağıgökdere	58	-	0	18	-	0	-
Gelendost	24	1	4,2	20	-	0	2.3
Total	194	5	2,6	180	4	2,2	2.4

In Isparta, where migratory beekeeping is practiced by many beekeepers, the number of permanent beekeepers is quite low. Many migratory beekeepers relocate their colonies more than twice a year. However, it is also a known fact that relocating colonies multiple times can cause stress in honeybees (UNEP, 2010). Moving colonies between locations with different climates and geographic structures does not directly cause bee mortality. However, by creating stress in bees, it triggers other factors that cause bee mortality. According to Ratia (2012), many factors influence bee losses, and stress related to migratory beekeeping is considered one of these factors (Özgür, 2012). In addition, the increase in Nosema disease in the country and around the world should be considered as infected beekeeping materials (Klee et al., 2007), the inclusion of carrier colonies and queen bees, and migratory beekeeping activities (Giersch et al., 2009; Whitaker et al., 2010; Büyük et al., 2014)

Nosemosis, one of the most common diseases seen in honeybees in Turkey and the world, is a fatal disease that causes serious decreases in honey yield, damages the country's economy, and causes colony losses (Yaman et al., 2015; Sinpoo et al., 2018; Tel et al. 2021).

Numerous studies have been conducted to identify nosemosis in Turkey, and its presence has been detected in various provinces (Kutlu, 1988; Aydın, 2006; Ütük et al. 2010; Yaman et al. 2015; Ütük et al. 2016; Yaman and Sağlam 2023; Yaman et al. 2023). To determine the prevalence of nosemosis among honeybees in the Kars region, 343 honeybees were examined, and 54 were determined to be infected with nosemosis (Topçu and Özkan Arslan 2004). In a study examining the presence, distribution, and pathogens of nosemosis in the Ordu region, the disease was detected in all 10 localities sampled. The infection rate was determined to range from 25 to 85% (Yaman et al. 2015). Zerek et al. (2020) examined adult bee samples from 450 hives in Hatay province for nosemosis. They

reported that 20% of the hives were infected with *Nosema*. Yaman and Sağlam (2023) examined the presence of nosemosis in bee colonies in Bolu province. The study found that 190 of the 3030 bee samples examined were infected with *Nosema* spp., and the average nosemosis rate was 6.3%.

According to the literature review, there is no other study in Isparta province, except for the master's thesis by Özgür (2012). This preliminary study, conducted by us based on current information, is of great importance for the current status of beekeeping in Isparta province. The current status of nosemosis, which has caused colony losses worldwide in recent years and has been detected in Isparta province, will be determined by molecular and microscopic identification and by investigating its distribution and density in Isparta, to determine whether it is caused by *Nosema apis* or *N. ceranae*.

CONCLUSIONS

The present study determined that bee colonies in Isparta were infected with *Nosema* spp. Also demonstrates that beekeepers in the Isparta region should be comprehensively informed about the necessary measures for monitoring and control of nosemosis.

ABSTRACT

Snapdragon (*Antirrhinum majus*) with a colorful flowers and aesthetic appeal, is a perennial plant belonging to the *Scrophulariaceae* family. Factorial arrangement based on a completely randomized design with four replications were conducted to investigate the effects of chitosan coated iron oxide nanoparticles (chitosan coated IONPs) (0, 50, 100, and 150 μM) and silver nanoparticles (AgNPs) (0, 50, 100, and 150 mg/L-1) on morphological and biochemical traits of the ornamental Snapdragon plant under greenhouse conditions. Measured indices included plant height, Branches Number, flower number and diameter, stomatal conductivity, total phenolic content, and chlorophyll fluorescence indices (F_v/F_o and F_m). The results indicated that the interaction effects of chitosan coated IONPs and AgNPs, especially at the concentrations of (100–150 μM) and (100–150 mg/L-1) mg/L respectively, significantly improved vegetative growth, flower production, and physiological indices. Increases in F_v/F_o and F_m enhanced photosynthetic efficiency and overall plant growth. Additionally, phenolic content was increased under AgNP treatments by activating the antioxidant defense system. These findings revealed that individual and combined use of nanoparticles can enhance Snapdragon performance, with potential applications in sustainable and high-quality ornamental plant production. Standardized testing protocols and regulatory oversight further complicates the evaluation of risks versus benefits.

Key words: Chlorophyll fluorescence, Nanoparticles, Snapdragon, Stomatal conductivity

INTRODUCTION

Snapdragon (*Antirrhinum majus*) with a colorful flowers and aesthetic appeal, is an important ornamental perennial plant belonging to the *Scrophulariaceae* family and native to the Mediterranean region. This plant cultivated as an annual in cold climates and as a biennial in temperate areas. In recent decades, nanotechnology has emerged as a revolutionary scientific advancement, opening new avenues for agriculture and sustainable resource management. Nanoparticles, due to their high surface area and unique physicochemical properties, have become promising tools for improving plant growth, pest control, and abiotic stress resistance. Among these nanoparticles, iron oxide (IONPs) and silver nanoparticles (AgNPs) have attracted attention due to their nutrient delivery capabilities and strong antimicrobial properties, respectively. Their application as bio-pesticides, protective agents, antimicrobials, and nutritional supplements has revolutionized agricultural practices. Studies showed that AgNPs can enhance plant growth parameters. In *Melissa officinalis*, significant increases in root and shoot biomass and length were observed under AgNP treatment, with maximum anthocyanin content at 60 ppm, attributed to time-dependent activation of antioxidant enzymes (Shahvali Bar &

Esmailzadeh Bahabadi, 2019). Other studies have shown that low concentrations of AgNPs can strengthen secondary metabolite production, such as flavonoids, thereby improving antioxidant capacity in plants (Jadczak et al., 2020; Liu et al., 2020). Chitosan, a natural polymer derived from chitin, not only stabilizes nanoparticles but also reduces their toxicity, enabling safer use in biological systems. On the other hand, chitosan-coated iron oxide nanoparticles is a biocompatible and provide stability against aggregation, making them suitable for managing environmental stress. In *Mentha piperita* under drought stress, chitosan coated IONPs improved chlorophyll fluorescence and photosynthetic indices (Torabi Giglou et al., 2022). This study investigates the synthesis, action mechanisms, and growth-promoting potential of IONPs and AgNPs nanoparticles in Snapdragon. The findings suggest that combining nanoparticles with chitosan coating may offer a novel strategy to enhance Snapdragon growth, stress tolerance, and ornamental or medicinal value

MATERIAL AND METHOD

Snapdragon seeds were prepared and cultivated under greenhouse conditions at Mohaghegh Ardabili University. Treatments included two nanoparticle types: AgNPs and chitosan coated IONPs, each at four concentrations: 0 (control), 50, 100, and 150 (mg/L-1 for AgNPs and μ M for chitosan coated IONPs). Treatments were applied via foliar spraying at three growth stages. Seeds were first sown in trays and then transplanted to pots containing a 1:1:1 mixture of organic matter, sand, and garden soil. The experiment carried out in a completely randomized factorial design with four replications. The measured morphological traits were plant height (± 1 mm), branch and flower number, and flower diameter (± 0.1 mm). For biochemical traits, total phenol, Chlorophyll fluorescence (Fv/F0 and Fm), and Stomatal conductivity were measured. Data were analyzed using SAS 9.1 software. Means were compared using Duncan's multiple range test, and graphs were prepared using Excel.

RESULTS AND DISCUSSION

Analysis of variance showed that both individual and interactive effects of chitosan coated IONPs and AgNPs significantly ($p < 0.01$) affected the plant height, branch and flower number, and flower diameter (Table 1). Biochemical indices including Fv/F, Fm, stomatal conductivity, and total phenol content also significantly affected by chitosan coated IONPs and AgNPs (Table 2).

*, ** and significant at the %5 and %1 and not significant probability levels, respectively.

PLANT HEIGHT

The results indicated that a significant increase in plant height was observed in plants treated with chitosan coated iron oxide nanoparticles at 50 μM and silver nanoparticles at 50 mg/L, However increasing the concentrations of silver nanoparticles (AgNPs) and chitosan coated iron oxide nanoparticles (chitosan coated IONPs) to 100 and 150 mg/L and μM , respectively, hadn't a positive effect on the final plant height. Increasing in the concentrations of chitosan coated iron oxide nanoparticles had the positive effect on final plant height, particularly at 100 μM , in combination with silver nanoparticles at 50 mg/L, which appeared to promote flower height (measured as the total plant height up to the last petal) (Figure 1A). The results showed that the lower concentrations of chitosan coated IONPs and AgNPs (0 mg/L and μM) had the lowest effects on plant height.

BRANCHES NUMBER

In the evaluation of the effects of chitosan coated iron oxide nanoparticles and silver nanoparticles on the branch numbers, the results were consistent with those observed for final plant height. The highest branches number was achieved in the treatment combining chitosan coated iron oxide nanoparticles at a concentration of 100 μM with silver nanoparticles at 50 mg/L (Figure 1B).

Figure 1. Interaction effects of chitosan Coated IONPs and AgNPs on Plant Height (A) and Branches Number (B) of Snapdragon

NUMBER OF FLOWERS

According to Figure 2A, by increasing the concentration of chitosan Coated IONPs and AgNPs the flower number was increased and the highest number of flowers was observed in chitosan-coated iron oxide nanoparticles at the concentration of 100 μM combined with 150 mg/L silver nanoparticles followed by the chitosan Coated IONPs at 150 μM of and 50 mg/L of AgNPs. The lowest flower number was in control (0 concentration of both chitosan coated IONPs and AgNPs).

Fv/F0

The results of experiment demonstrated that increasing the concentration of silver nanoparticles (AgNPs) across all levels led to an enhancement in the Fv/Fm ratio. The highest Fv/Fm value was observed at 150 mg/L of silver nanoparticles combined with 150 μM of chitosan coated IONPs. Conversely, a high concentration of iron oxide nanoparticles (150 μM) in the absence of silver nanoparticles resulted in a decline in this parameter followed by control (Figure 2B).

Figure 2. Interaction effects of chitosan Coated IONPs and AgNPs on Flower number (A) and Fv/F0 Ratio (B) in Snapdragon

Fm

The comparison of mean values across traits revealed that a moderate concentration of iron (50 μM) played a significant role in enhancing the Fm (maximum fluorescence). However, the highest Fm value was achieved from 150 mg/L of silver nanoparticles (AgNPs). Increasing the concentrations of chitosan coated iron oxide nanoparticles combined with various concentrations of silver nanoparticles, resulted in a reduction of Fm (Figure 3A).

STOMATAL CONDUCTIVITY

The mean comparison of data showed that the use of chitosan coated iron nanoparticles at moderate concentrations (50 and 100 μM) combined with various concentrations of silver nanoparticles had a positive effect on stomatal conductivity in the leaves of snapdragon. However, this value was

relatively lower compared to control plants, with the highest stomatal conductivity observed in the control group (Figure 3B).

Figure 3. Interaction effects of chitosan Coated IONPs and AgNPs on the Fm (Maximum Fluorescence) (A) and Stomatal conductivity (B) in Snapdragon

TOTAL PHENOL

The results of experiment revealed that by increasing in the concentration of chitosan coated iron oxide nanoparticles (IONPs) from 0 to 150 mg/L, the phenol content increased significantly ($p < 0.01$) across all treatments. The mean comparison showed that the highest total phenol levels were observed in chitosan coated IONPs at the rate of 100 and 150 mg/L combined with higher concentrations of silver nanoparticles (AgNPs). In contrast, the control treatment without IONPs and AgNPs showed the lowest phenol content (Figure 4A).

FLOWER DIAMETER

According to the results obtained from the effects of different concentrations of chitosan-coated iron oxide nanoparticles and silver nanoparticles, as presented in Figure 4B, the lowest number of flowers was recorded in the control treatment (0 mg/L silver nanoparticles and 0 μM chitosan coated iron oxide nanoparticles), while the highest number was observed in the treatment with 150 mg/L silver nanoparticles combined with 0 μM chitosan-coated iron oxide nanoparticles. Moreover, the findings indicated a direct correlation between the increase in flower number and the elevated concentrations of both types of nanoparticles.

Figure 4. Interaction effects of chitosan Coated IONPs and AgNPs on total phenol content (A) and flower diameter (B) in snapdragon

DISCUSSION

According to the results of this experiment, chitosan coated IONPs at the rate of 100–150 μM significantly enhanced vegetative growth and flower production in Snapdragon which is consistent with the results of Rahmatizadeh et al. (2019) research, they results revealed that iron nanoparticles could increase the plant height, biomass, and Fe content in tomato plants. Torabi Giglou et al. (2023) conducted a study to investigate the effects of chitosan coated IONPs on peppermint and they found that this treatment could improve the photosynthetic capacity. In this study the similar results was obtained and nanoparticles enhanced chlorophyll fluorescence and stomatal conductivity of snapdragon. AgNPs played a synergistic role by increasing total phenolic and activating antioxidant systems, consistent with Ribeiro et al. (2023), who observed ROS-mediated defense activation via Ag/Fe nanoparticle combinations. Chitosan, as a biopolymer coating, not only stabilized nanoparticle delivery but also contributed to plant health. Hence, the combined use of chitosan coated IONPs and AgNPs created a synergistic effect, significantly improving morphological traits, photosynthetic performance, and biochemical defenses in Snapdragon, highlighting their potential in sustainable ornamental horticulture.

CONCLUSIONS

This study demonstrated that the combined application of chitosan-coated iron oxide and silver nanoparticles, particularly at moderate to high concentrations, can effectively improve growth and physiological traits in Snapdragon. These nanoparticles enhanced plant height, branching, and flowering while also increasing chlorophyll fluorescence and phenolic compounds. These findings support the strategic use of biocompatible nanoparticles in ornamental plant management as a promising approach for boosting performance and resilience, particularly within sustainable and eco-friendly agricultural systems.

ABSTRACT

Bacteriocins are ribosomally synthesized peptides that typically exhibit antimicrobial activity against closely related bacterial species. Their production is considered a significant biochemical feature, particularly due to their role in biopreservation applications, such as the prevention of food spoilage and contamination. Various bacterial species, including enterococci, are capable of producing bacteriocins. In recent years, increasing attention has been directed toward the identification of novel bacteriocin-producing strains, their characterization, and the exploration of the potential applications of these peptides.

In this study, the bacteriocin production capacities of *Enterococcus faecium* DP8.3, DP9.3, and *E. mundtii* DP35.1 strains, previously isolated from traditional Turkish cheeses, as well as the modes of action of the bacteriocins produced by these strains, were evaluated. The analyses revealed that all strains began producing bacteriocins at the 5th hour of incubation at 37°C, reaching maximum production levels by the 8th hour. Bacteriocin production exhibited a positive correlation with cell density. The modes of action of the bacteriocins were tested against vancomycin-resistant *E. faecium* ATCC 51559. The bacteriocins produced by *E. faecium* DP8.3 and DP9.3 exhibited bactericidal effects, whereas the bacteriocin produced by *E. mundtii* DP35.1 demonstrated a bacteriostatic effect. The results demonstrate the potential application of *E. faecium* DP8.3 and DP9.3 strains in food systems due to their inhibitory effects. Additionally, the bacteriocin produced by *E. mundtii* DP35.1 appears to be a promising candidate for further investigation, particularly regarding its potential synergistic effects when combined with various antibiotics or other antimicrobial bacterial strains. Moreover, further studies are recommended to evaluate the applications of the bacteriocins produced by *E. faecium* DP8.3, DP9.3, and *E. mundtii* DP35.1 in the food industry.

Keywords: *Enterococcus*, Bacteriocin production, Mode of action

INTRODUCTION

Preservation methods are employed in the food industry to extend the shelf life of products by preventing spoilage and reducing the occurrence of food-related health risks (Singh, 2018). In recent years, growing consumer awareness and the increasing demand for healthy eating have led to heightened interest in natural preservatives as alternatives to chemical additives. In parallel with these developments, research and development efforts focused in biopreservation techniques have accelerated considerably. Although various techniques are employed for biopreservation, the use of beneficial bacteria to maintain and enhance product quality is among the prominent approaches. In this context, the shelf life of products can be extended through the use of various microorganisms or antimicrobial compounds derived from lactic acid bacteria (LAB). In addition to their role in the

development of characteristic taste, aroma, and textural properties of food products, LAB also produce compounds such as organic acids, hydrogen peroxide, ethanol, and bacteriocins, which contribute to their preservative effects (O'Connor et al., 2020; Kasimin et al., 2022).

Bacteriocins are ribosomally synthesized antimicrobial peptides. Although they are typically effective against closely related microorganisms, certain broad-spectrum bacteriocins are capable of inhibiting a wide range of microbial species (O'Connor et al., 2020). Bacteriocins synthesized by enterococci are known as enterocins. These compounds, composed of low molecular weight peptides, are classified into four distinct classes (Franz, et al., 2007). Enterocins exhibit specific antimicrobial activity, effectively inhibiting the growth of Gram-positive bacteria and spoilage microorganisms (Moreno et al., 2006).

Bacteriocins exhibiting optimal biopreservative potential are characterized by their safety for human consumption, minimal effect on the human microbiota, effectiveness against foodborne pathogens and spoilage microorganisms, and stability within the food matrix which they are applied (O'Connor et al., 2020). Moreover, bacteriocin-producing LAB are regarded as promising alternatives to antibiotics, owing to their capacity to survive in the gastrointestinal environment, suppress pathogenic and competing microbes, modulate host immune response, and mitigate both inflammation and oxidative stress, thereby contributing to improved gut health (Dobson et al., 2012; Dahiya et al., 2017; Westfall et al., 2017; Bäuerl et al., 2017). The growing interest in bacteriocins is further supported by several factors: the increasing consumer demand for minimally processed foods free from chemical additives (Silva et al., 2018); their capacity to modulate the human microbiota (Garcia-Gutierrez et al., 2019); their potential to serve as natural alternatives to antibiotics in response to rising antimicrobial resistance (Cotter et al., 2013); and their application as bacteriocin-producing probiotic cultures aimed at improving animal health and reducing infections (Vieco-Saiz et al., 2019).

The investigation of the production and mode of action of bacteriocins is of great importance due to their potential contributions to enhancing food safety, controlling antibiotic-resistant pathogens, and developing natural alternatives to synthetic additives. In this context, the present study examined the production and mode of action of bacteriocins produced by *E. faecium* DP8.3 and DP9.3, and *E. mundtii* 35.1, which were previously isolated from traditional Turkish cheeses.

MATERIAL AND METHOD

Bacterial strains and growth conditions

The bacteriocin-producing strains *E. faecium* DP8.3, DP9.3, and *E. mundtii* DP35.1 used in this study were previously isolated from traditional Turkish cheeses obtained from the Isparta province of Türkiye (Akpınar Kankaya, 2024). In the experiments, the strains were cultivated in de Man Rogosa and Sharpe (MRS) broth (Biokar, France), at 37°C for 24 h prior to use. All strains were stored at -32°C with 20% (v/v) sterile glycerol.

Bacteriocin production

For bacteriocin production, active cultures were inoculated at 1% (v/v) into 100 mL of MRS broth and incubated at 37°C for 12 h. During the incubation period, the optical density (OD) at 600 nm was measured at 1-h intervals, and antimicrobial activity was assessed concurrently. Bacteriocin activity was quantified as arbitrary units per milliliter (AU/mL), using vancomycin-resistant *E. faecium* ATCC 51559 as the indicator strain (Gök Charyyev et al., 2019).

Mode of action of bacteriocin

The mode of action of bacteriocins produced by *E. faecium* DP8.3, DP9.3, and *E. mundtii* DP35.1 was determined by adding 20 mL of pH-adjusted (pH 6.0) cell-free supernatant (CFS) to 100 mL cultures of vancomycin-resistant *E. faecium* ATCC 51559 at the early exponential growth phase. Cultures were incubated at 37°C for 12 h, with optical density (OD) at 600 nm measured at hourly intervals. A culture of *E. faecium* ATCC 51559 without bacteriocin addition served as the control (Todorov and Dicks, 2005).

RESULTS AND DISCUSSION

Within the scope of this study, bacteriocin production by *E. faecium* and *E. mundtii* strains, previously isolated from traditional Turkish cheeses, was investigated. It was observed that all isolates initiated bacteriocin production at the 5th h of incubation in MRS broth at 37°C, reaching maximum production at the 8th h.

In analyses determining the bacterial growth of *E. faecium* DP8.3 via OD measurements at 600 nm, the initial OD was recorded as 0.035 and increased to a maximum of 1.701 by the 11th h of incubation. Bacteriocin activity produced by *E. faecium* DP8.3 reached its peak at 400 AU/mL against *E. faecium* ATCC 51559 at the 8th h, when the OD was 1.274 (Figure 1). Although OD continued to increase up to the 12th h, bacteriocin production remained stable at 400 AU/mL during this period.

Figure 1. Growth curve of *E. faecium* DP8.3 at 37°C under uncontrolled pH conditions (●) and bacteriocin production expressed as AU/mL (■)

Similarly, bacteriocin production by *E. faecium* DP9.3 commenced at the 5th h and reached a maximum activity of 200 AU/mL at the 8th h (Figure 2). The initial OD of *E. faecium* DP9.3 was 0.042, increasing to 1.612 by the 12th h of incubation. At the 8th h, when the maximum bacteriocin activity against *E. faecium* ATCC 51559 was determined as 200 AU/mL, the OD was 1.110. From that point onward, bacteriocin activity remained constant at 200 AU/mL.

For *E. mundtii* DP35.1, bacteriocin production also began at the 5th h of incubation. The initial OD was recorded as 0.066 and increased to 1.736 by the 12th h (Figure 3). Bacteriocin production, against *E. faecium* ATCC 51559 reached a maximum level of 400 AU/mL at the 8th h of incubation. After this point, bacteriocin activity remained stable until the 12th h of incubation.

Figure 2. Growth curve of *E. faecium* DP9.3 at 37°C under uncontrolled pH conditions (●) and bacteriocin production expressed as AU/mL (■)

Figure 3. Growth curve of *E. mundtii* DP35.1 at 37°C under uncontrolled pH conditions (●) and bacteriocin production expressed as AU/mL (■)

The initiation of bacteriocin production during the growth phase and its reaching a maximum level at the end of this phase in all strains indicate that the bacteriocins produced follow primary metabolite kinetics. This observation is consistent with previous studies reporting primary metabolite kinetics for bacteriocins produced by *Enterococcus* species (Gök Charyyev et al., 2019; Altınkaynak and Tuncer, 2020; Mancini et al., 2025). Similarly, Gök Charyyev et al. (2019) reported that *E. faecium* YT52, isolated from boza, began bacteriocin production at the 2nd h of incubation, with maximum production reaching 6400 AU/mL at the end of the logarithmic growth phase (7th h). Likewise, *E. mundtii* YB6.30, isolated from sucuk, was reported to initiate bacteriocin production at the 4th h of incubation, with activity increasing in parallel with cell density and peaking at the 9th h (Altınkaynak and Tuncer, 2020). Valledor et al. (2022) found that bacteriocin production by *E. faecium* ST20Kc and ST41Kc, isolated from kimchi, started during the early logarithmic growth phase (3 h after inoculation), and that the highest level of bacteriocin production was detected at the 6th h of incubation, with an activity of 12800 AU/mL against *L. monocytogenes* ATCC 15313. Mancini et al. (2025) documented that bacteriocin activity of *E. faecium* RM12, a raw milk isolate, was first detected at the

3rd h of incubation against *L. monocytogenes* ATCC 19115, and reached a maximum level of 16000 AU/mL at the 9th h.

In studies investigating the modes of actions of bacteriocins produced by *E. faecium* DP8.3, DP9.3, and *E. mundtii* DP35.1 against *E. faecium* ATCC 51559, CFS containing bacteriocins were individually added to early exponential phase cultures of *E. faecium* ATCC 51559. The OD of the cultures was measured hourly over a 12-h period. Following the addition of CFS from *E. faecium* DP8.3 at the 3rd h of incubation, no further increase in OD was observed in the treated culture, whereas the control culture showed a continuous increase in OD (Figure 4).

Figure 4. Mode of action of CFS from *E. faecium* DP8.3 on the growth of *E. faecium* ATCC 51559 in the absence (■) and presence (●) of CFS

In the investigation of the bacteriocin produced by *E. faecium* DP9.3, CFS containing the bacteriocin was added to the *E. faecium* ATCC 51559 culture at the 3rd h of incubation. In the group treated with bacteriocin-containing CFS, a decrease in OD was observed until the 8th h, after which it remained constant (Figure 5). In contrast, the control group exhibited a continuous increase in optical density throughout the incubation period.

Figure 5. Mode of action of CFS from *E. faecium* DP9.3 on the growth of *E. faecium* ATCC 51559 in the absence (■) and presence (●) of CFS

CFS containing the bacteriocin produced by *E. mundtii* DP35.1 was added to the *E. faecium* ATCC 51559 culture at the 3rd h of incubation. In the treated group, cell density declined until the 9th h, followed by a renewed increase beginning at the 10th h (Figure 6). In contrast, the OD of the untreated *E. faecium* ATCC 51559 control culture exhibited a continuous increase throughout the incubation period.

Figure 6. Mode of action of CFS from *E. mundtii* DP35.1 on the growth of *E. faecium* ATCC 51559 absence (■) and presence (●) of CFS

Upon examining the modes of action of the bacteriocins produced by all strains, it was determined that those produced by *E. faecium* DP8.3 and DP9.3 exhibited bactericidal activity. The bactericidal activity of these bacteriocins suggest their potential application as biopreservatives in the food industry. Similarly, studies conducted by various researchers have reported that bacteriocins produced by different enterococcal strains exhibit bactericidal effects against sensitive indicator bacteria, consistent with the data obtained in this study (Gök Charyyev et al. 2019; Altınkaynak and Tuncer 2020; Valledor et al. 2022; Meral Aktaş, 2024; Mancini et al., 2025). For example, Gök Charyyev et al. (2019) reported that the addition of CFS derived from *E. faecium* YT52, isolated from boza, to an early exponential phase culture of *L. monocytogenes* ATCC 15813 resulted in growth inhibition. Altınkaynak and Tuncer (2020) observed a decrease in the OD of *E. faecium* ATCC 51559 upon the addition of bacteriocin-containing CFS from *E. mundtii* YB6.30, isolated from sucuk, indicating a bactericidal effect. Valledor et al. (2022) reported that the OD of *L. monocytogenes* ATCC 15313 and *E. faecalis* 200A remained unchanged following treatment with bacteriocin-containing CFSs from *E. faecium* ST20Kc and ST41Kc, isolated from kimchi, suggesting bactericidal activity. In another study, the addition of bacteriocins produced by *E. faecium* H108 and H206, isolated from raw bovine milk, were found to immediately inhibit the growth of *L. monocytogenes* ATCC 7644 (Meral Aktaş, 2024). Mancini et al. (2025) also reported that no significant increase in OD was observed in *L. monocytogenes* ATCC 19115 cultures treated with the CFS of *E. faecium* RM12, a raw milk isolate, in comparison to untreated controls.

On the other hand, the bacteriocin produced by *E. mundtii* DP35.1 demonstrated a bacteriostatic effect against *E. faecium* ATCC 51559, which may be attributed to an insufficient bacteriocin concentration. Similarly, Qiao et al. (2020) reported that low concentrations of bacteriocin produced by *E. faecium* TJUQ1 were unable to completely eliminate *L. monocytogenes* CMCC 1595. In a different study, Pingitore et al. (2012) reported that the bacteriocins CRL35 and ST88Ch, produced by *E. mundtii* CRL35 and *E. faecium* ST88Ch, caused an extended lag phase when added to 3-hour-old cultures of *E. faecalis* ATCC 19443 and *Lb. sakei* ATCC 15521. Due to its bacteriostatic effect,

further investigation is warranted into the combined use of this bacteriocin produced by *E. mundtii* DP35.1 with antibiotics or other inhibitory strains, as well as its potential applications in the food industry.

CONCLUSIONS

In this study, the production and modes of action of bacteriocins produced by *E. faecium* DP8.3, DP9.3, and *E. mundtii* DP35.1 strains were investigated. All strains initiated bacteriocin production at the 5th h of incubation, reaching maximum levels by the 8th h. To evaluate their modes of action against vancomycin-resistant *E. faecium* ATCC 51559, CFS containing bacteriocins were added to *E. faecium* ATCC 51559 cultures at the 3rd h of incubation. The results demonstrated that *E. faecium* DP8.3 and DP9.3 exhibited bactericidal effects, whereas *E. mundtii* DP35.1 showed a bacteriostatic effect. The bactericidal activity observed in *E. faecium* DP8.3 and DP9.3 against the vancomycin-resistant strain is particularly significant, given the increasing global concern over antibiotic-resistant pathogens and their impact on food safety and public health. These findings highlight the promising potential of these strains as natural biopreservative agents. In contrast, the bacteriostatic effect of *E. mundtii* DP35.1 suggests that its efficacy may be enhanced through synergistic application with other antimicrobial agents or hurdles, warranting further investigation.

ABSTRACT

The genus *Maesa* Forssk., belong to the Myrsinaceae family and comprising some 150 species distributed throughout the Old World. In this study, the antioxidant, and antidiabetics properties of (hexane, ethyl acetate, methanol, n-butanol and water) extracts of *Maesa kamerunensis* that grows naturally in the Cameroon were investigated. ABTS⁺ scavenging, β -carotene-linoleic acid, Cupric-reducing antioxidant capacity (CUPRAC), DPPH[•] scavenging, and metal chelating assays were performed to evaluate antioxidant activities of the extracts. The enzyme inhibitory potential of extracts was investigated against key enzymes involved in antidiabetics (α -amylase and α -glucosidase). The spectrophotometric methods were used to determine the total phenolic, flavonoid, ascorbic acid, β -carotene, and lycopene contents. Among the extracts tested, the crude extract of stems showed the highest antioxidant activity in CUPRAC ($A_{0.50}$: 9.34 ± 0.71 μ g/mL), ABTS⁺ (IC_{50} : 3.27 ± 0.25 μ g/mL), DPPH (4.09 ± 0.45 μ g/mL), β -carotene linoleic acid (IC_{50} : 6.18 ± 0.25 μ g/mL) assays. At 200 μ g/mL, the ethyl acetate extract of *M. kamerunensis* was more active against α -glucosidase and α -amylase enzymes with the IC_{50} at 10.61 ± 0.31 and 12.07 ± 0.37 respectively, follow by the methanol extract of fruits with IC_{50} at 28.65 ± 0.44 and 22.20 ± 0.13 respectively. This study contributes to the traditional therapeutic uses of *M. kamerunensis* and emphasizes its value in the development of new therapeutic agents exhibiting antioxidant and anti-diabetic activity.

Keywords: *Maesa kamerunensis*, antidiabetic potential, antioxidant proprieties,

INTRODUCTION

Since ancient times, food and natural products have been used in different parts of the world as traditional medicine, depending on their high therapeutic efficacy in treating various diseases. To date, using natural products offers high biocompatibility with marginal side effects. Thus, they have contributed to the development of up to 50% of the approved drugs in the market (Kamarudin et al. 2017). Traditional herbal medicines have played a fundamental role in preventing and treating various ailments since ancient times, which are rich sources for new drug discovery (Shendge and Belemkar 2018). The prescribed drugs derived from higher plants have increased by 25% in the last few decades (Khaliq 2017). The WHO has declared that 11% of the 252 drugs are from plant sources, while various synthetic drugs have natural precursors (Saleem, et al. 2019). Especially with the worldwide spread of diseases such as diabetes mellitus (DM), cardio-metabolic, cancer, and Alzheimer's diseases (AD) are

being focused on safe and consistent natural drugs over synthetic ones and side effects (Mocan et al. 2016).

Diabetes is a multifactorial metabolic disorder characterized by aberrant carbohydrate metabolism and high glucose levels. Alarming, the WHO has predicted diabetes to be the 7th leading cause of death by 2030, with the expected rise in the diabetic population to 418 million in 2025 and 552 million by 2030 (Federation 2019). Diabetes mellitus is an important metabolic problem characterized by insulin deficiency or no response to insulin in cells. Diabetes mellitus is categorized as a complex metabolic disease associated with irregular insulin production, developing insulin resistance, and β -cell malfunction. The intestinal absorption and breakdown of carbohydrates are majorly regulated by the enzymes α -amylase and α -glucosidase. A major intention is to discover natural α -amylase and α -glucosidase enzyme inhibitors. Inhibitors of α -amylase and α -glucosidase are becoming the target enzymes for possible drug development. These enzymes play a key role in hydrolyzing long-chain carbohydrates and disaccharides into monosaccharides, respectively (Jhong et al. 2015). The literature has a number of documentation that identify plant extracts as a viable source to relieve diabetes and through inhibitory actions against amylase and glucosidase. Despite these findings, there is still an ongoing need to study novel plant sources as antidiabetic medications. The aim of this study was to investigate the antioxidant and antidiabetic activities of various extracts obtained from fruits and the stems of *M. kamerunensis*.

MATERIAL AND METHOD

The fruits, leaves and the stems bark of *Maesa kamerunensis* was collected in Bangang, West Region of Cameroon, in July 2020. Authentication was performed in the Cameroon National Herbarium in Yaounde, where our sample was deposited under the voucher number 56111/HNC.

Extraction

The materials were dried in the shade at room temperature, then crushed. The powder resulting (3.1 Kg; 1.7 kg and 2.2 kg respectively of fruits, leaves and stems bark respectively) was extracted by maceration, three times, with MeOH. After filtration, the filtrate was evaporated dry under reduced pressure to give a crude extract of 115.1 g (fruits), 85 g of leaves and 33.5 g stems bark extract. The crude extract of the fruits and the stems bark of *M. kamerunensis* has been partitioned with hexane, ethyl acetate and n-butanol using liquid-liquid extraction. We obtained hexane; ethyl acetate, n-butanol and aqueous extracts.

Antidiabetic activity

α -Amylase and α -glucosidase inhibition assay

The α -amylase inhibitory activity was measured using by starchiodine method with slight modifications (Küçükaydın et al., 2021). α -amylase (from porcine pancreas) solution (0.1 units/mL) was prepared with phosphate buffer (20 mM pH = 6.9 phosphate buffer prepared with 6 mM NaCl). Then, 50 mL of α -amylase solution and 25 mL of sample solution were mixed in a 96-well microplate. The mixture was pre-incubated for 10 min. at 37 °C. Following pre-incubation, 50 mL of starch solution (0.05 %) was added and incubated for 10 min. at 37 °C. HCl (0.1 M, 25 mL) and Lugol (100 mL) solutions were added to complete the reaction and absorbance was measured at 565 nm in 96-well microplate. Acarbose was used as standard.

The α -glucosidase inhibitory activity was determined according to Kim et al. (2010) with modifications (Küçükaydın et al., 2021). 50 mL of α -glucosidase (from *Saccharomyces cerevisiae*) (0.1 units/mL) in phosphate buffer (0.01 M pH = 6.0), 25 mL of PNPG (4-N-nitrophenyl- α -Dglucopyranoside) in phosphate buffer (0.01 M pH = 6.9), 50 mL of phosphate buffer (0.01 M pH = 6.9) and 10 mL of sample solution were mixed in a 96-well microplate. The solution was incubated for 20 min. at 37 °C.

Antioxidant assay

Samples were investigated for antioxidant activities with regards to lipid peroxidation inhibition, CUPRAC, DPPH* and ABTS*⁺ scavenging and ferrous ion chelating assays as described by Çayan et al., 2019. α -Tocopherol, BHA and EDTA were used as reference compounds. The results of antioxidant activity are stated as IC₅₀ and A_{0.50} (effective concentration providing 0.50 absorbance for CUPRAC assay) values.

RESULT AND DISCUSSION

Antioxidants activities

The crude extracts of fruits (MKFM) and the stems bark (MKSM), the ethyl acetate fractions (MKFE; MKSE), the aqueous fractions (MKSW; MKFW) and the hexane fractions (MKFH) of *M. kamerunensis* were evaluated for their antioxidant activities. The results are grouped in the **Table 1** below.

Table 1: Antioxidant activity of the extracts by β -Carotene-linoleic acid, DPPH*, ABTS*⁺, CUPRAC and metal chelating assays^a

Antioxidant Activity					
	β -Carotene-linoleic acid assay	DPPH* assay	ABTS* ⁺ assay	CUPRAC assay	Metal chelating assay
	IC ₅₀ (µg/mL)	IC ₅₀ (µg/mL)	IC ₅₀ (µg/mL)	A _{0.50} (µg/mL)	IC ₅₀ (µg/mL)
MKFH	50.67±0.84	45.17±0.21	29.95±0.25	53.85±0.86	80.19±0.39
MKFB	44.47±0.61	26.37±0.51	17.33±0.60	35.83±0.49	105.2±0.91
MKSB	38.44±0.76	25.36±0.62	20.23±0.36	31.79±0.81	81.78±0.80
MKFE	26.73±0.59	13.05±0.83	8.05±0.53	18.79±0.90	57.90±0.25
MKSM	6.18±0.25	4.09±0.45	3.27±0.25	9.34±0.71	16.72±0.17
MKFM	50.21±0.29	25.67±0.29	6.40±0.12	36.71±0.57	54.35±0.73
MKSW	20.09±0.18	22.50±0.88	17.63±0.21	23.61±0.40	35.27±0.70
MKFW	>200	>200	>200	>200	>200
α -Tocopherol	2.25±0.07	38.15±0.45	35.50±0.56	61.40±0.75	NT ^b
BHA	1.40±0.03	19.82±0.33	12.80±0.08	25.50±0.43	NT ^b
EDTA	NT ^b	NT ^b	NT ^b	NT ^b	5.60±0.45

^a Values represent the means $\pm$ SEM of three parallel sample measurements ($p < 0.05$). ^c NT: not tested.

From this table, the crude extract of stem's bark (MKSM) presented the lowest value of IC₅₀ using β -Carotene-linoleic acid assay with IC₅₀ at 6.18±0.25 µg/mL comparing to the value of references, IC₅₀=2.25±0.07 µg/mL for α -Tocopherol and IC₅₀=1.40±0.03 µg/mL for BHA. With DPPH* assay, it

showed the value IC_{50} at $4.09 \pm 0.45 \mu\text{g/mL}$ comparing to the standart at $IC_{50} = 38.15 \pm 0.45 \mu\text{g/mL}$ for α -Tocopherol and $IC_{50} = 19.82 \pm 0.33 \mu\text{g/mL}$ for BHA. This extract exhibited the lowest value of IC_{50} at $3.27 \pm 0.25 \mu\text{g/mL}$ when tested to $ABTS^{++}$ assay and was more active than the value of standard. When used CUPRAC assay, it showed the IC_{50} at $(9.34 \pm 0.71 \mu\text{g/mL})$ comparing to the value of standard at $IC_{50} = 61.40 \pm 0.75 \mu\text{g/mL}$ and $IC_{50} = 25.50 \pm 0.43 \mu\text{g/mL}$ for the α -Tocopherol and BHA respectively. This extract has also been evaluated using Metal chelating assay and it showed the value of IC_{50} at $16.72 \pm 0.17 \mu\text{g/mL}$ comparing to the refrence's (EDTA) value at $IC_{50} = 5.60 \pm 0.45 \mu\text{g/mL}$. The ethyl acetate fraction (MKFE) of *M. kamerunensis* exhibited the moderated activities. It presented the value of IC_{50} at $13.05 \pm 0.83 \mu\text{g/mL}$ for the DPPH[•] assay and $8.05 \pm 0.53 \mu\text{g/mL}$ for the $ABTS^{++}$ assay. It was more active than the crude extract. This can be explain by the manifestation of antagonistic effet.

The crude extract of fruit (MKFM) showed the lowest value of IC_{50} at 6.40 ± 0.12 using the $ABTS^{++}$ assay comparing to the one of references at 35.50 ± 0.56 and 12.80 ± 0.08 for α -Tocopherol and BHA respectively. It were more active than the reference. With DDPH and CUPRAC assays, it exhibited moderate activities with the low value of IC_{50} in relation to standard's one. The hexane fraction (MKFH) showed generally the higher value of IC_{50} comparing to the value of standard in the all assay done. The aqueous fraction of stems bark (MKSW) presented the moderate potent antioxidant activities with the IC_{50} at 23.61 ± 0.40 using CUPRAC assay and the aqueous fraction of fruits (MKFW) showed weak activities for all assays.

Antidiabetic activity

Antidiabetic activities of the extracts were performed using α -amylase and α -glucosidase enzymes, which are key enzymes involved in the hydrolysis of carbohydrates and intestinal absorption respectively. α -Amylase and α -glucosidase inhibitory activities of extracts and fractions are given in Table 2.

α -amylase inhibitory activity

The best α -amylase inhibitory activity was observed in the ethylacetate fraction with IC_{50} at $12.07 \pm 0.37 \mu\text{g/mL}$ followed by the methanol extract of the fruit of *M. Kamerunensis* with IC_{50} at $22.20 \pm 0.13 \mu\text{g/mL}$. The n-butanol fraction showed an IC_{50} at $66.91 \pm 0.85 \mu\text{g/mL}$ and its crude extract at $70.11 \pm 0.90 \mu\text{g/mL}$ Table 2.

α -Glucosidase inhibitory activity

The α -glucosidase inhibitory activity results of the crude methanol extracts, and fractions from *M. kamerunensis* are given in Table 2. It was seen that all obtained extracts exhibited α -glucosidase inhibitory activity in a dose-dependent manner. The water fraction of stems demonstrated the highest inhibitory effect on α -glucosidase with the IC_{50} at $22.34 \pm 0.51 \mu\text{g/mL}$, follow by crude extract and n-butanol fractions with IC_{50} at 22.71 ± 0.69 and $22.80 \pm 0.35 \mu\text{g/mL}$ compared to acarbose ($22.34 \pm 0.51 \mu\text{g/mL}$).

Table 2: Antidiabetic inhibitory activities of the samples^a

Samples/ Standards	Anti-diabetic activity			
	α -glucosidase		α -amylase	
	IC_{50} ($\mu\text{g/mL}$)	Inhibition (%) (at 200 $\mu\text{g/mL}$)	IC_{50} ($\mu\text{g/mL}$)	Inhibition (%) (at 200 $\mu\text{g/mL}$)
MKFH	26.45 ± 0.38	82.88 ± 0.80	21.08 ± 0.35	85.31 ± 0.86
MKFB	27.09 ± 0.37	82.36 ± 0.93	30.87 ± 0.46	80.58 ± 0.75
MKSM	22.71 ± 0.69	85.33 ± 0.43	109.4 ± 0.63	61.33 ± 0.56

MKFM	>200	28.65±0.44	>200	22.20±0.13
MKFE	>200	10.61±0.31	>200	12.07±0.37
MKFW	23.61±0.78	84.23±0.58	91.74±0.77	67.86±0.55
MKSW	22.34±0.51	86.28±0.75	75.22±0.45	70.11±0.90
MKSB	22.80±0.35	85.53±1.12	94.90±0.86	66.91±0.85
Acarbose	22.34±0.51	57.70±0.75	32.50±0.45	83.10±0.27

From these results, the stems extract of *M. kamerunensis* could have the relation between it antioxidant and antidiabetics activities.

CONCLUSIONS

In this study, the antioxidant and antidiabetics inhibitory properties of various extracts of the fruits and stems of *M. kamerunensis*, which is naturally distributed in West region of Cameroon, were investigated. According to β -carotene-linoleic acid, ABTS+, CUPRAC DPPH free radical scavenging and iron chelating methods, the methanol extract of stems exhibited higher antioxidant activity than all other extracts. The water extracts of stems showed significant α -glucosidase inhibition activity. The ethyl acetate extract from the fruits has higher α -amylase inhibitory activity among all extract, even than acarbose. This study represents the first report on the detailed analysis of various parts of *M. kamerunensis* for their antioxidant and in vitro antidiabetic enzyme inhibitory activities. Our results showed that this species has promising bioactivities. They can be used as a natural source of antioxidant, antidiabetic agent in food, cosmetic and pharmaceutical industries. Therefore, further studies are needed to isolate and identify antioxidant and antidiabetic components from these species.

ABSTRACT

Diabetes mellitus (DM) represents a global health problem. It is the most common of the endocrine disorders and is characterized by chronic hyperglycemia due to relative or absolute lack of insulin secretion or insulin actions. According to the World Health Organization projections, the diabetes population is likely to increase to 300 million or more by the year 2025. Complementary and alternative approaches to diabetes management such as isolation of phytochemicals with anti-hyperglycemic activities from medicinal plants is therefore imperative. The current study aim to identify new compounds by a systematic study of the anti-oxidant and anti-diabetic activity of stems of *M. kamerunensis*. Phytochemicals were isolated from the methanolic extract of stem parts of the plant by column chromatography and identified by nuclear magnetic resonance spectroscopy and mass spectroscopy. A new triterpenoid saponin glycoside was isolated. The isolated phytochemicals were identified as 3β -O- $\{([\alpha$ -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-galactopyranosyl-(1 $\rightarrow$ 3)]- $[\beta$ -D-galactopyranosyl-(1 $\rightarrow$ 2)]- β -D-glucopyranosyl $\}$ -22 α -(2-methylbutanoyl)-13 β ,28-oxido-olean-16 α ,28 α -diol (**1**) and 3β -O- $\{([\alpha$ -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-galactopyranosyl-(1 $\rightarrow$ 3)]- $[\beta$ -D-galactopyranosyl-(1 $\rightarrow$ 2)]- β -D-glucuronopyranosyl $\}$ -21 α -angeloyloxy,22-(*E*)-cinnamoyl)-13 α ,28-oxido-olean-16 β ,28 β -diol (**2**). For the antioxidant activities, compound **1** showed the higher value of IC₅₀ at 124.8 $\pm$ 1.15 μ g/ml for β -Carotene-linoleic acid assay and 185.3 $\pm$ 1.10 for ABTS^{•+} assay. For antidiabetic potential activities, compound **1** elicited stronger α -glucosidase (IC₅₀ = 36.80 $\pm$ 0.73) and moderate α -amylase (IC₅₀ = 28.05 $\pm$ 0.54 g/ml) inhibitory activities as compared to acarbose. Overall, the data suggested that the saponin isolated from *M. kamerunensis* has potentials as natural antioxidants and antidiabetics.

Keywords: *M. kamerunensis*; saponin; antioxidant activity; antidiabetic activity; α -Glucosidase; α -amylase.

INTRODUCTION

Medicinal plants and their derived components have provided potent drugs for modern medicine including vincristine, quinine, morphine, and digoxin to fight against life-threatening diseases such as diabetes, cancer, coronary heart diseases, HIV/Aids, and neurological conditions [Adhami et al., 2018]. Plant-derived molecules are also significant as pharmacological probes, drug prototypes and drug precursors that lead to the discovery of bioactive and innovative compounds or drugs [Parveen et al., 2018]. Therefore scientists are actively seeking new compounds from natural and traditional resources. *Maesa kamerunensis* belong to the *Maesa* genus and it is an important member of the Myrsinaceae family. Several species of the genus *Maesa* have many uses in traditional medicine and presented divers biological activities among antidiabetic, antitumor, antibiotic, piscicidal, antifungal, antimutagenic and antifungal (Foubert et al., 2016). It has also been reported that *Maesa* species contain flavonoid, triterpenoid and saponins as majors secondary metabolites compounds (Foulbert et al., 2016; Simbawee et al., 1999). Saponins, the natural glycosides of steroid or triterpene are pharmaceutical and nutraceutical agents mostly present in plant leaves and roots. These possess hypocholesterolemic, antidiabetic, anticoagulant, hepatoprotective, anticarcinogenic, hypoglycemic, neuroprotective, immunomodulatory, anti-inflammatory, antimicrobial and antioxidant activity, leading to significant concentration on their benefit to be used as vaccine adjuvants (Koneri et al., 2014; Thao et al., 2014; Astuti et al., 2011). Estimation of total saponins in plants is a routine practice that needs to be more elaborated in terms of antioxidant and antidiabetic efficacy of isolated saponins. Phytochemicals are isolated by extraction with numerous polarity based solvents and these constituents exhibit variation in their chemistry and ultimately solubility in specific solvent (Sultana et al., 2009). Despite the natural abundance and widespread use, data on biological activities of saponins in different solvents and the isolated saponins is limited.

Researchers are working hard to explore not only the causative factors of diabetes but also to find new molecules to target those factors in order to develop novel therapies. Among the common causative factors of diabetes several, such as auto-oxidation of glucose that results from the free radical formation, receptor tyrosine kinases, including insulin receptor and epidermal growth factor receptor, mediate protein tyrosine phosphatase (PTPs), which are involved in the down-regulation of various cellular signaling transduction mechanisms, and the enzyme glucosidase may be considered as an initial target to screen out potential antioxidant and antidiabetic molecules in order to find innovative molecules via various ways [Parthiban et al., 1995; Abdelsalam et al., 2019]. The purpose of the present study was to investigate the phytochemical composition of n-butanol fraction of stems of *M. kamerunensis* and the evaluation of their antioxidant and antidiabetic activities.

MATERIALS AND METHODS

Plant materials

The stems bark of *Maesa kamerunensis* was collected in Bangang, West Region of Cameroon, in July 2020. A botanist of the Cameroon National Herbarium in Yaoundé performed authentication, where our sample was deposited under the voucher number 56111/HNC.

Extraction

The materials were dried in the shade at room temperature, then crushed. The powder resulting (2.2 kg) of stems bark was extracted by maceration, three times, with MeOH. After filtration, the filtrate was evaporated dry under reduced pressure to give a crude extract of 33.5 g stems bark extract. For antioxidants, antidiabetics, we used methods previously described by Küçükaydın et al., 2021.

Isolation

The most active extract, the methanol extract of the stems (33.0 g) of *M. kamerunensis* was suspended in 300 mL of water and then partitioned with ethyl acetate and n-butanol (BuOH). The resulting n-BuOH fraction were concentrated to dryness to give crude extract. It was subjected to a silica gel column with gradient elution of CHCl₃/MeOH/H₂O. The fractions have been collected and combined under the basis of TLC yielding six fractions FA-FF. Fraction C (5 g) was subjected to sephadex LH20 and eluted with MeOH. Five subfractions was grouped under the basis of TLC indexed FC1-FC5. Fraction FC2 (1.1 g) was further subjected to a reversed phase silica gel column with isocratic elution of H₂O/MeOH, yielding cinq fractions FC2A-FC2E. Subfraction FC2B was purified using sephadex LH20 and eluted with MeOH isocratically to give compound **1** (15 mg). Fraction E was chromatographed to C-18 reversed phase silica gel column eluting with a stepwise gradient mixture of H₂O/MeOH to obtain three fractions FE1-FE3. The repeated column chromatography column using C-18 reversed phase silica gel of fraction FE2 eluted with isocratic H₂O/MeOH, followed by Sephadex LH-20 allowed us to obtain compound **2** (12.2 mg).

Biological activities

Antidiabetic activity

α -Amylase and α -glucosidase inhibition assay

The α -amylase inhibitory activity was measured using by starchiodine method with slight modifications (Küçükaydın et al., 2021). The α -glucosidase inhibitory activity was determined according to Kim et al. (2010) with slight modifications (Küçükaydın et al., 2021).

RESULTS AND DISCUSSION

In the search for new antioxidant and anticholinesterase compounds from plant materials, we discovered that methanol of the stems *M. kamerunensis* presented, higher activities that the methanol fruits extract suggesting that the extract contains antioxidant and anticholinesterase compounds. When that MeOH extracts were partitioned by ethyl acetate and n-BuOH, the resulting n-BuOH layer showed a strong activity comparing to the ethyl acetate, water and even standard tested.

Structural Elucidation of the Active Compounds Isolated from *M. kamerunensis*

The HRESIMS spectrum of compound **1** showed a molecular ion at m/z 1220.6190 [M]⁺, 1219.6151 [M - H]⁺, which is consistent with the molecular formula C₅₃H₉₆O₂₆ (calculated m/z 1220.6190) and C₅₃H₉₅O₂₆ (calculated m/z 1219.6112) respectively. The Fragment peaks appeared at m/z 1073 [M - 147]⁺ and 911 [M - 147 - 162]⁺ due to the losses of a rhamnose terminal unit, and two hexose units respectively. The ¹H and ¹³C NMR spectra showed that compound **1** is a triterpenoid glycoside with four sugar moieties. The interpretation of its spectroscopic and spectrometric data allowed us to assign it structure **1** and was unambiguously characterized as 3 β -O-{([α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-galactopyranosyl-(1 $\rightarrow$ 3)]-[β -D-galactopyranosyl-(1 $\rightarrow$ 2)]-[β -D-glucopyranosyl]}-22 α -(2-methylbutanoyl)-13 β ,28-oxido-olean-16 α ,28 α -diol.

Compound (**2**) was obtained as white powder, had a molecular formula of $C_{68}H_{100}O_{28}$, and determined from its negative ESIMS and ^{13}C DEPT NMR data. ^1H and ^{13}C NMR spectra indicated that compound **2** had the same sugar arrangement as that of **1**. The aglycon of both compounds **2** was identical to that of maesargentoside IV [Foubert et al., 2016]. 1D and 2D NMR spectra of compounds **5** revealed the same position (C-21) of esterification with angelic acid, and showed the presence of a cinnamoyl group at position 22 of the aglycon. Based on the coupling constant (16.0 Hz) between the olefinic protons H-2 and H-3, the (*E*)-configuration of the cinnamoyl group was established. Compound **2** could be identified as 3 β -O- $\{([\alpha$ -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-galactopyranosyl-(1 $\rightarrow$ 3)]- β -D-galactopyranosyl-(1 $\rightarrow$ 2)]- β -D-glucunopyranosyl)-21 β -angeloyloxy-22 α -(*E*)-cinnamoyloxy-13 β ,28-oxidoolean-16 α ,28 α -diol.

Scheme: structures of saponins isolated from *M. Kamerunensis*

Biological activities

In vitro antioxidant activity

As seen in Table 1, saponins as well as the standard antioxidant BHT scavenged the ABTS radical in a concentration dependent-manner.

The **compound (1)** showed the value of IC_{50} at 166.1 ± 0.93 mL using β -Carotene-linoleic acid and the 185.3 ± 1.10 mL using $ABTS^{++}$ assay and compound **2** presented the $IC_{50} > 200$ mL using all methods. This could be due to the fixation of 2-methylbutanoyl group at the position C-21 of compound 1.

Table.. Antioxidant activity of the isolated compounds by β -Carotene-linoleic acid, DPPH $^{\bullet}$, $ABTS^{++}$, CUPRAC and metal chelating assays^a

Antioxidant Activity					
	β -Carotene-linoleic acid assay	DPPH $^{\bullet}$ assay	$ABTS^{++}$ assay	CUPRAC assay	Metal chelating assay

Antidiabetics activities

Our results displayed that saponins extract forms *M. kamerunensis* having inhibitory potentials enzymes. *M. kamerunensis* saponin strongly inhibited α -glucosidase activity and inhibition of α -amylase activity (Table 2). The inhibitory activity elicited by compound **1**, IC_{50} 36.80 $\pm$ 0.73 μ g/ml on α -glucosidase was stronger than that of the standard, acarbose (57.70 $\pm$ 0.75 mg/ml). While in the case of α -amylase, it displayed a better inhibition with IC_{50} at 28.05 $\pm$ 0.54 μ g/ml compared to the value of reference (acarbose, 83.10 $\pm$ 0.27). The compound **2** inhibited α -glucosidase with the value of IC_{50} at 48.70 $\pm$ 0.85 μ g/ml and 33.74 $\pm$ 0.77 for the α -amylase activity.

Table 2: Antidiabetic inhibitory activities of the samples^a

Anti-diabetic activity				
Samples/ Standards	α -glucosidase		α -amylase	
	Inhibition		Inhibition	
	IC_{50} (μ g/mL)	(%) (at 200 μ g/mL)	IC_{50} (μ g/mL)	(%) (at 200 μ g/mL)

MKSK	>200	48.70 $\pm$ 0.85	>200	33.74 $\pm$ 0.77
Acarbose	128.5 $\pm$ 0.62	57.70 $\pm$ 0.75	32.50 $\pm$ 0.45	83.10 $\pm$ 0.27

^a Values represent the means $\pm$ SEM of three parallel sample measurements ($p < 0.05$).

NT: not tested.

The reduction of activities could be due to the fixation of 2-methylbutanoyl group at position C-21.

CONCLUSION

The aim of this work was to isolate and purify secondary metabolites from one medicinal plant in Cameroon: *M. kamerunensis* and evaluate their antioxidant and antidiabetic activities. During the phytochemical investigations, two saponins were isolated and characterized using chromatographic and spectroscopic techniques, particularly 1D and 2D NMR and mass spectrometry. Compound **1** showed the highest antioxidant and antidiabetic activity. The results of this study clearly demonstrated that saponins from *Maesa kamerunensis* stems exhibit free radical scavenging activities and possess reducing power making it an excellent candidate in the treatment of diseases in which ROS has been implicated. It can be used to prevent diabetic complications. Hence, the above findings have given scientific evidence to saponins, a class of phytochemical from *M. kamerunensis* stems as potent antioxidant that can be employed in the management of diabetes.

ACKNOWLEDGEMENT

The authors appreciate University of the Cape Town, South Africa for NMR analysis.

ABSTRACT

Coriander (*Coriandrum sativum* L.) is an annual, medicinal, and aromatic plant species belonging to the Apiaceae family. Widely used in traditional medicine and the food industry as a spice and flavoring agent, coriander is noted for its anti-inflammatory, antimicrobial, and digestive-regulating properties. Morphologically, coriander grows to a height of 30–60 cm, with a cylindrical and usually branched stem. The lower leaves are petiolate, broad, and lobed; the middle leaves are sessile; and the upper leaves are narrower, thread-like, and deeply lobed. The flowers are pink or white, and the fruits are spherical, 3–5 mm in diameter, and rich in essential oils. In Turkey, coriander is primarily cultivated in the Central Anatolia and Mediterranean regions, while globally it is widely grown in countries such as India, Iran, and Mexico.

This review aims to examine the medicinal and aromatic uses, botanical characteristics, and current cultivation status of coriander in Turkey and worldwide, based on the recent literature.

Keywords: *Coriandrum sativum*, Medicinal Plant, Review

INTRODUCTION

Medicinal and aromatic plants have played a significant role in human life throughout history due to their use for both nutritional and therapeutic purposes. Today, these plants are used across a range of fields, from the food industry to pharmaceutical products. Coriander (*Coriandrum sativum* L.), one of medicinal and aromatic plants, is an annual medicinal and aromatic species belonging to the Apiaceae family. It is widely used in traditional medicine and the food industry, and its fruits and leaves contain nutritionally and pharmacologically valuable components (Gil et al., 2002; Sahib et al., 2013). Evidence of the medicinal and aromatic properties of coriander, also known as "kişniş", "kuzbere" and "aşotu" in Turkey, dates back to 1500 BC. First used by the Egyptians, extracts and essential oils derived from the seeds and other parts of this plant are reported to have various pharmacological effects. Among these effects, sedative, muscle-relaxant, antimicrobial, antioxidant, anti-inflammatory, analgesic, and antispasmodic properties stand out. Because of these qualities, coriander has been considered an important medicinal and aromatic plant, valued for centuries in both

folk medicine and the pharmaceutical industry (Özel et al., 2010). Although the natural distribution area of coriander is Southern Europe and the Mediterranean Basin, it is now grown in many regions of the world thanks to its ability to adapt to different climatic conditions (Hazeri et al., 2021). On a global scale, Russia, various Asian countries, and Morocco stand out in coriander production; in particular, South Asian countries hold a leading position in terms of production volume (Ulutaş Deniz et al., 2018). In Turkey, the plant naturally occurs in the Central, Eastern, and Southeastern Anatolia regions, while its cultivated production is concentrated in specific areas, primarily the provinces of Mardin, Gaziantep, Burdur, Erzurum, Denizli, and Isparta (Kan, 2007). Statistics on coriander cultivation area and production amount in our country have been recorded since 2012. While 1 ton of production was achieved on only 11 decares of cultivation area in 2012, by 2016 the cultivation area had expanded to 503 decares and production had increased to 42 tons. Certain fluctuations were observed in the following years, and especially in 2019, the cultivation area decreased to 155 decares, and the production amount decreased to 12 tons (TUIK, 2019). However, from 2020 onwards, production began to show an upward trend again, with the cultivation area increasing to 2,455 decares and production reaching 188 tons that year. This data demonstrates that the production potential and market value of coriander in Turkey have been steadily increasing in recent years. However, it is noteworthy that production decreased to 101 tons and the cultivation area decreased to 1841 decares in 2024. This situation reveals that fluctuations in production continue and that sustainability in coriander cultivation may vary depending on various environmental, economic, or agricultural factors (TUIK, 2024).

Table 1. Coriander plant cultivation areas and production quantities in Turkey.

Production year	Area (Decare)	Production (Ton)
2015	150	11
2016	503	42
2017	410	29
2018	405	29
2019	155	12
2020	2 455	188
2021	2 612	253
2022	1 571	204
2023	1 932	222
2024	1 841	101

(TUIK, 2024)

Coriander is an annual herbaceous plant that can grow to a height of 30–60 cm, with thin, spindle-shaped roots, an upright stem, and alternate leaves. The lower leaves are broadly segmented and petiolate, the middle leaves are segmented and short-stemmed, and the upper leaves are stemless, thin and threadlike, and have deep lobes. The stem is erect, gnarled, and marked with longitudinal striations, branching primarily in its upper portions. The flowers of the plant are white or pinkish and

are arranged in an umbrella shape at the ends of the branches. Each flower also contains five petals, five sepals, five stamens, and a two-part stigma. The plant flowers in June–July and produces round fruits consisting of two pericarps; the fruits are yellowish brown, spherical, and their diameter varies between 3–5 mm (Baytop, 1984; Diederichsen, 1996; Baydar, 2009; Burdock and Carabin, 2009). In Turkey, coriander cultivation is carried out mainly in hot and arid climate regions. The plant exhibits optimal growth in well-drained, calcareous, sandy-loam soils with a light texture and neutral to slightly alkaline pH (Beyzi and Gürbüz, 2010; Verma et al., 2011). Cultivation is generally carried out in October–November. For optimal growth, the plant requires temperatures between 20–26 °C. The frequency and amount of irrigation vary depending on the climate, soil characteristics, and soil moisture. (Singh et al., 2015).

Coriander has two subvarieties: *C. sativum* L. var. *macrocarpum* and *C. sativum* L. var. *microcarpum*. The primary criteria for distinguishing these varieties are thousand-seed weight and fruit diameter. Those with a fruit diameter greater than 3 mm and a thousand-seed weight greater than 10 g are classified as macrocarpum, while those with a fruit diameter of 3 mm or smaller and a thousand-seed weight less than 10 g are classified as microcarpum (Diederichsen, 1996). While the entire coriander plant is suitable for consumption, the most preferred parts from a nutritional perspective are the fruit and leaves. Rich in essential oils (0.03–2.6%), phenolic compounds, and flavonoids, coriander is noted for its antimicrobial, antioxidant, and anti-inflammatory activities (Nadeem et al., 2013; Laribi et al., 2015). The volatile oil content of mature, dried coriander seeds ranges from 0.03% to 2.6%, whereas the fixed oil content varies between 9.9% to 27.7%. The seeds are particularly rich in volatile oils and polyphenols, while the leaves are notably rich in vitamins (Bhat et al., 2014). Approximately 40% of the essential oil is present in the fruit peel, while 60% is located in the seeds (Özel et al., 2009). The stems, leaves, and fruits of the plant contain linalool-rich aromatic compounds, which contribute to its characteristic aroma and flavor, while the leaves and fruits also serve as an important nutritional source, providing protein, vitamins, minerals (Ca, P, Na, Zn), and carbohydrates. Moreover, the fruits contain valuable fatty acids, including petroselinic, linoleic, oleic, palmitic, and stearic acids (Kassahun, 2020). The high content of vitamin C (160 mg/100 g), vitamin A (β -carotene 12 mg/100 g) and vitamin B12 (60 mg/100 g) in the leaves makes coriander more valuable from a nutritional point of view (Girenko, 1982; Prakash, 1990). The main components of coriander essential oil are linalool (67.7%), α -pinene (10.5%), γ -terpinene (9.0%), geranyl acetate (4.0%), camphor (3.0%) and geraniol (1.9%), which are responsible for both the characteristic aroma of the plant and its potential functions in medicinal and therapeutic products. All these characteristics highlight the strategic importance of coriander in terms of both agricultural production and commercial value. However, the essential oil composition of coriander is not constant and varies significantly depending on many factors, such as genotype, climatic and seasonal conditions, geographical characteristics, planting time, cultivation methods, plant developmental stage, fertilizer applications, harvest period, abiotic stress factors, and storage duration and conditions (Arganosa et al., 2008; Özel et al., 2010).

Coriander is an annual medicinal plant widely used throughout the world due to its medicinal properties as well as its nutritional value (Laribi et al., 2015). Similarly, it is used in our country due to its appetite-stimulating, digestive system-regulating, cough-suppressing, and headache-relieving

impacts (Ulutaş Deniz et al., 2018). Essential oils and fatty acids extracted from dried fruits are commercially utilized in the food, beverage, plastics, cosmetics, and detergent industries. In addition, they play a role in storage processes due to their insecticidal properties and heavy metal-binding potential (Kassahun, 2020).

Coriander leaves are known to contain higher levels of bioactive compounds and have strong antioxidant properties (Chithra and Leelamma, 1999; Melo et al., 2002; Wangenstein et al., 2004). Antioxidants are known as molecules that prevent or repair cellular damage caused by oxidative stress in living organisms (Msaada et al., 2017). In biological systems, reactive oxygen species (ROS), such as hydroxyl radicals and superoxide anions, can induce DNA damage and oxidize cellular lipids and proteins (Li et al., 2015; Peng et al., 2014; Xu et al., 2017). Oxidative stress-induced damage can be mitigated through increased intake of exogenous antioxidants, which function as free radical scavengers by inhibiting the initiation or propagation of oxidative chain reactions (Baiano and del Nobile, 2015). In general, a balance is achieved between oxidation and antioxidation by clearing these radicals by the antioxidant system in the body. Natural antioxidants of plant origin are mostly in the form of polyphenols (flavonoids, phenolic acids, anthocyanins, stilbenes and lignans), carotenoids (carotenes, xanthophylls) and vitamins (vitamins E and C) (Manach et al., 2004; Baiano and del Nobile, 2015). The antioxidant capacity of the plant is primarily attributed to its pigments, which are particularly rich in carotenoids. Studies have demonstrated that the carotenoids in coriander extract possess a strong potential to scavenge hydroxyl radicals, thereby protecting cells from oxidative damage (Divya et al., 2012). In addition to conferring nutritional benefits to the plant, these phytochemicals function as antioxidants, contributing to the extension of food product shelf life and offering protection against free radical-induced damage in humans.

CONCLUSIONS

Coriander (*Coriandrum sativum* L.) is an important spice as well as a medicinal plant due to its nutritional and aromatic properties. The composition of essential oils in its leaves, stems, flowers, and fruits is influenced by species, cultivation conditions, environmental factors, and post-harvest processing (Mandal and Mandal, 2015). Therefore, a comprehensive scientific evaluation of coriander's essential oils and bioactive compounds will contribute to the more effective, safe, and sustainable use of the plant in food, pharmaceutical, and health applications. Owing to its high antioxidant content, coriander stands out both as a functional food additive and as a natural therapeutic agent, and a more detailed investigation of its biological effects would provide significant contributions to the fields of food science and health.

ABSTRACT

In this study, the soil nitrogen transformation dynamics of inhibitor-enriched urea formulations were investigated in both protected tomato cultivation (field trial in Söğüt, Bilecik), unplanted pot trials (controlled conditions in Antalya), and in an open field pepper plantation in Dörtdeğirmen, Gediz. A total of six formulations, including uncoated urea and a Max 46 reference formulation, were evaluated for total nitrogen (N), ammonium (NH₄⁺), and nitrate (NO₃⁻) contents at different time points. In field trials, soil samples were collected on days 7 and 16 after application. In pot trials, three samplings were carried out over 14 days. The results revealed that Formula 3 maintained higher total nitrogen and ammonium levels, consistently with lower nitrate formation, and demonstrated superior nitrogen use efficiency. Controlled pot trials confirmed the field findings and highlighted the compensatory effects of inhibitors in delaying nitrification. These results highlight the potential of inhibitor formulations to reduce nitrogen loss, extend fertilizer life, and contribute to sustainable agriculture.

Keywords; Urea inhibitor, nitrogen efficiency, ammonium, nitrate, tomato greenhouse, pot trial, NBPT

INTRODUCTION

Agricultural soils contribute significantly to global anthropogenic nitrous oxide (N₂O) emissions. Approximately 50–60% of anthropogenic N₂O emissions are attributed to direct or indirect emissions from nitrogen (N) fertilization in agricultural systems (Tian et al., 2020; Canadell et al., 2021). These N₂O emissions from agricultural soils primarily arise from microbially mediated processes in the soil, such as denitrification, nitrification denitrification, nitrification, and dissimilar nitrate reduction (Braker and Conrad, 2011; Butterbach-Bahl et al., 2013). Nitrogen productivity in agricultural systems is critically affected by the rapid conversion of urea to nitrate, which in turn leads to significant leaching and volatilization. To prevent this, inhibitors such as NBPT (N-(n-butyl)thiophosphoric triamide) are added to urea fertilizers to retard nitrification and preserve nitrogen in the ammonium form. The microbial processes responsible for N₂O production depend on soil oxygen (oxic/anoxic) conditions and the availability of N and carbon (C) in the soil (Chen et al., 2014). Since N₂O emissions vary with local conditions such as climate, management practices, and soil type (Ruser et al., 2017), site-specific N₂O reduction strategies are essential. Enhanced efficiency fertilizers (EEFs) containing inhibitors such as nitrification inhibitor [NI], urease inhibitor [UI] and dual inhibitors [NIUI], controlled-release urea (CRU) and controlled-release bulk blend fertilizer (CRBF) have been proposed as an effective approach to maintain high crop yields and reduce reactive N (Nr) losses (Li et al., 2017; Lan et al., 2022a). This study evaluates the performance of six inhibitor-based urea formulations in three different experimental settings: an open-field protected tomato greenhouse

(with crops) in Söğüt and controlled pot trials (without crop effects) in Antalya. The Triple approach allows comprehensive evaluation of fertilizer behavior in both real-world and isolated environments in an open-field pepper plantation in Gediz Dörtdeğirmen region.

MATERIAL AND METHOD

In the inhibitor synthesis project, field trials are being conducted across different land and climate conditions to monitor developmental processes. Within the scope of the project, field trials were conducted at different locations, tailored to different climates and soil types. Two different plant species, namely tomatoes and peppers, were tested in two open fields. Additionally, empty pot trials were conducted in Antalya. Six urea inhibitor formulations were tested on tomatoes in a closed greenhouse in the village of Çaltı, Söğüt, Bilecik, in open fields tested according to different soil types. Six urea inhibitor formulations were used in open field trials in Dörtdeğirmen village, Gediz district, Kütahya. Pot trials were conducted at the YLDZ Laboratory in Döşemealtı, Antalya, and six urea inhibitor formulations were tested. Care was taken to leave a 20 cm fertilization space between plants in the test areas. The fertilization method used was an equal amount of product, totaling 10 g, on each plant.

RESULTS AND DISCUSSION

For nitrogen to be in its most permanent (persistent) form in the soil:

In inhibitory urea studies, high ammonium and relatively low nitrate indicate that nitrogen is retained in the soil for longer periods.

- High Total Nitrogen means a generally higher amount of nitrogen in the soil, meaning an abundant nitrogen source.
- High Exchangeable Ammonium because ammonium retains its cation binding sites in the soil for longer periods, making nitrogen more resistant to leaching and loss.
- Low Exchangeable Nitrate because nitrate is a very mobile form, easily leached by water, and not persistent in the soil. Therefore, a low exchangeable nitrate is advantageous for persistence.
- For "persistence," in particular: • High Total Nitrogen • High Exchangeable Ammonium (the permanent nitrogen form) • Low Exchangeable Nitrate

If we examine the formulas we use based on these findings,

Table 1. Bilecik Söğüt Çaltı 1 empty 6 prescription application Sampling results

Bilecik Söğüt Çaltı 1 empty 6 prescription application 1. Sampling results					Bilecik Söğüt Çaltı 1 empty 6 prescription application . Sampling results				
#	SAMPLE	Total Nitrogen (N)	Ammonium nitrate	Exchangeable Nitrate	#	SAMPLE	Total Nitrogen (N)	Ammonium nitrate	Exchangeable Nitrate
1	Ref.	0,44	0,04	0,34	1	Ref.	0,53	0,10	0,25
2	1.Formula	0,53	0,06	0,38	2	1.Formula	0,45	0,09	0,33
3	2.Formula	0,69	0,27	0,33	3	2.Formula	0,45	0,09	0,31
4	3.Formula	1	0,33	0,21	4	3.Formula	0,60	0,11	0,25
5	4.Formula	0,32	0,16	0,67	5	4.Formula	0,48	0,08	0,22
6	5.Formula	0,61	0,13	0,30	6	5.Formula	0,61	0,10	0,31

8	Max46	0,53	0,06	0,38	8	Max46	0,74	0,08	0,26

Among the first trial results, in Figure 3. area the third formula has the highest total nitrogen and ammonium content, making it the most persistent nitrogen in the soil. The second test was conducted with samples taken 16 days later. It appears that NBPT successfully delays nitrate conversion. Nitrate levels are very controlled in the third formula.

Table 2. Kütahya Gediz Dörtdeğirmen 1 empty 6 prescription application Sampling results

#	SAMPLE	Total Nitrogen (N)	Ammonium nitrate	Exchangeable Nitrate
1	Ref.	0,29	0,01	0,28
2	1.Formula	0,17	0,06	0,38
3	2.Formula	0,24	0,27	0,33
4	3.Formula	0,25	0,33	0,21
5	4.Formula	0,16	0,16	0,67
6	5.Formula	0,28	0,13	0,30
7	6.Formula	0,25	0,06	0,27
8	Max46	0,27	0,06	0,38

To interpret the results in the Gediz Dörtdeğirmen region:

The low total nitrogen in Formula 1 indicates nitrogen loss. The slightly high ammonium level suggests that the inhibitory effect may have been partially maintained. However, the low nitrate level indicates that nitrification remains limited, meaning there is some inhibitory effect. Formula 2 yielded results very close to the reference formula. Total nitrogen: Only 0.03% lower – acceptable nitrogen loss. Ammonium level: Same as the reference the inhibitory effect is successful. Nitrate level: Slightly lower this indicates that the conversion of NH_4^+ to nitrate is suppressed, meaning the inhibitory effect

is maintained. Formula 3 generally yields results close to the reference: Total nitrogen: 0.25% Low nitrogen loss, which is positive. Ammonium: 0.01% Lower than the reference This indicates that the inhibitory effect is weakened. Nitrate: 0.24% Almost the same as the reference, which indicates that nitrification is limited. The inhibitory effect is moderate. Formula 4 showed a weak inhibitory effect: Total nitrogen is very low (0.16%) This low level indicates that nitrogen is being lost and is not being retained sufficiently in the system. Ammonium level is low NH_4^+ has been converted, limiting its inhibitory effect. Nitrate is also low Nitrification may not have occurred completely, but this may also be due to low total nitrogen. Formula 5 appears strong in terms of nitrogen preservation, but its inhibitory effect is weak. Total nitrogen (0.28%) is higher than the reference, which is positive (nitrogen is well preserved). Ammonium (0.01%) is low – its inhibitory effect is weak. Nitrate (0.27%) is high – its nitrification rate is higher than the reference. Its inhibitory effect is weak, but it performs best in terms of total nitrogen. Formula 6 shows good nitrogen preservation (0.25%), with only a 0.02% loss. Ammonium is low (0.01%), indicating a slight weakening of the inhibitory effect. Nitrate is very close. (0.24%), indicating that the NH_4^+ , NO_3^- conversion is limited. It has a moderate inhibitory effect. Consequently, it was determined that Formula 3 achieved maximum efficiency.

Total Nitrogen Retention in the Antalya potted plant-free trials:

Formulas generally retain nitrogen at or above the reference level. The lowest nitrogen rate is in the reference (0.43%), while other formulas significantly prevented nitrogen loss.

Inhibitory Effect:

The strongest inhibitory effect is seen in Formula 6 and Formula 3. These formulas exhibit high NH_4^+ values and an $\text{NH}_4^+/\text{NO}_3^-$ ratio of 1 or above.

Nitrification Level:

Controlled nitrification ensures a slow and balanced release of nitrogen. A slight increase in Formula 1 may indicate rapid release.

Slow Release and Balanced Performance: If the goal is slow release and minimizing nitrogen loss, Formula 3 and Formula 6 stand out. Formula 3 offers a more balanced profile, while Formula 6 provides a slightly stronger inhibitory effect and slows nitrification. Because the Witness Formula has no inhibitory effect, nitrogen undergoes nitrification more rapidly and has a higher release rate.

Performance closest to the reference: Formula 5 and Formula 4. Slow release and strong inhibitor: Formula 6 and Formula 3. Best nitrogen retention: Formula 1 (but nitrification is slightly faster).

CONCLUSION

Inhibitor-enriched urea formulations can improve nitrogen retention and balance nitrification in both field and controlled conditions. Formulations 3 and 6 are strong candidates when slower release is desired; Formula 1 is excellent at retaining total N, but rate/timing adjustments may be required to reduce NO_3^- accumulation. Formula 3 yielded the best results against the established commercial product. Further multiseason trials with yield and quality endpoints are recommended to refine usage guidelines based on soil type and climate.

PROPOLIS AGAINST BOTRYTIS CINEREA: A REVIEW OF STUDIES COMBINING IN VITRO AND IN VIVO TESTS

Ömer Ümit OKÇU, Nuray ÖZER

1 Tekirdağ Namık Kemal University, Faculty of Agriculture, Plant Protection Department, Tekirdağ, Türkiye

Corresponding author e-mail: ouokcu@nku.edu.tr

ABSTRACT

Botrytis cinerea is a necrotrophic fungal pathogen that is responsible for substantial losses in a wide range of plant species. The detrimental impacts of chemical fungicides on human health and the environment have given increase the interest in alternative control strategies. In this review, the antifungal effects of different propolis extracts on this pathogen were evaluated based on studies that combined *in vitro* and *in vivo* tests. The findings of the *in vitro* experiments demonstrated that propolis extracts have the capacity to inhibit various developmental stages of this pathogenic fungus such as mycelial growth, sporulation, and conidial germination. However, the effectiveness of this inhibition was changed with concentration of the extract and the method of preparation. In this context, it has been demonstrated that extracts prepared based on the use of ethanol at high concentration and sonication method have a stronger antifungal effect. *In vivo* test demonstrated that the treatment of propolis to the fruits of plants including strawberries, grapes, blueberries and tomatoes led to a reduction in both the disease incidence and infection area by the pathogen, although this effect exhibited the variability with plant species, the application method and dosage. Consequently, while propolis reveals considerable antifungal potential against *B. cinerea*, additional researches are required on the standardization of extracts, the optimization of doses, the determination of application timing and *in vivo* tests on different plant species to increase its applicability in agricultural practices.

Keywords: *Botrytis cinerea*, propolis extract, antifungal effect, *in vitro* and *in vivo* tests

INTRODUCTION

Propolis is a complex natural compound that is formed by honeybees (*Apis mellifera*) by combining the natural substances they collect from plant buds, resins and leaf sap with their own enzymatic secretions. The word 'propolis' is derived from the Greek word's 'pro', meaning 'front or entrance', and 'polis', meaning 'city-colony', which indicates that it was used in its hive defense. Propolis is characterised by its flexibility, softness and stickiness at high temperatures, while it becomes hard and brittle when cooled. Due to these properties, it is used by honeybees to close cracks and holes and strengthen the structure of beeswax combs in order to keep the temperature and humidity inside the hive constant throughout the year (Sforcin, 2007).

From antiquity to the present, propolis has been utilized as an antiseptic and disinfectant for oral and skin illnesses in ancient Greece, primarily in traditional medicine, and by the Egyptians during mummification procedures (Havsteen, 1983; Burdock, 1998). This particular bee product, which has a wide range of uses, has been shown to contain over 300 chemical compounds (Huang et al., 2014). The chemical composition of raw propolis typically consists of 50% plant resins, 30% waxes, 10% essential and aromatic oils, 5% pollen, and 5% other organic substances (Bankova, 2005). However, the main chemical groups in propolis resin are phenolic acids and their esters, terpenes, flavonoids,

aromatic aldehydes and alcohols, stilbenes, fatty acids, and β -steroids (Watanabe et al., 2011; Ahangari et al., 2018; Przybylek and Karpinski, 2019). Despite the chemical diversity of propolis, comprehensive research has revealed the existence of at least six main types (Ghallab et al., 2024).

Figure 1. The main types of propolis (Ghallab et al., 2024).

Following the demonstration of the anticancer, antioxidant, anti-inflammatory, antibiotic, antifungal and antihepatotoxic properties of propolis by Ghisalberti (1979), there has been an increase in the number of modern controlled experimental studies on the chemical structure and biological activities of this substance. *Botrytis cinerea*, the causal agent of gray mold disease in several plant species and a major cause of yield losses both in the field and post-harvest (Williamson et al., 2007; Dean et al., 2012), took a place among the fungal pathogens against which propolis was tested. The ability of this fungal pathogen for development of resistance exhibited by this fungal pathogen to fungicides has rendered the use of alternative compounds to control it, such as propolis, increasingly significant.

Some of the studies have been conducted *in vitro* to investigate the impact of propolis on *B. cinerea* (Sapieha-Waszkiewicz et al., 2011; Curifuta et al., 2012; Yang et al., 2016; Ezazi and Davari, 2018; Wuaden et al., 2018; Ouahab et al. 2023; Erdoğan and Güzel, 2025). However, the results of *in vivo* tests involving plant parts are more significant in determining the practical applicability of this compound. In this review, the effect of propolis against this pathogen was discussed in the light of the findings obtained from both *in vitro* and *in vivo* stages, with emphasis placed on the highest effects observed in the studies. Within this context, *in vitro* studies are incorporated into the text according to their chronological sequence, while *in vivo* studies are presented in tabular form. Articles belonging to the research conducted until today were obtained by using many databases in Tekirdağ Namık Kemal University library.

Studies on The Effects Of Different Propolis Extracts and Applications on *Botrytis cinerea*

In the study conducted by Darweesh (2010), samples of propolis collected from Baghdad, Iraq, were prepared using 96% ethyl alcohol and subsequently added to Potato Dextrose Agar (PDA) medium at doses of 1.25, 2.5, and 5 mg/ml. The researcher then has determined the pathogen's colony diameter and mycelial growth rate seven days after placing a mycelial disk of the pathogen in the center of each petri dish. In the study, the same concentrations were also added to Potato Dextrose Broth (PDB) medium and mycelial dry weights were measured after 14 days of incubation at 25°C. *In vitro* tests of the study revealed that a concentration of 5 mg/mL of propolis extract led to a 100%

reduction in both the colony growth and the mycelial dry weight in PDA and PDB media. This dose was applied to eggplant leaves and cucumber fruit, and its efficacy against the pathogen *in vivo* was tested (Table 1). In addition, the chemical composition of propolis was analysed using infrared spectroscopy, and the presence of flavonoids was determined.

In a study conducted by Moura et al. (2016), extracts of two different types of propolis (green and brown) prepared with ethanol were added to PDA medium, which were present in 9 cm Petri dishes at doses of 0.5% and 2.5%, and the mycelial disk of the pathogen was placed on it. Petri dishes were incubated at 25°C and the colony diameter of the pathogen was measured at 48, 72 and 96 hours after inoculation. Following a thorough evaluation of the study's findings, it was determined that both 0.5% and 2.5% doses of green propolis exhibited a higher antifungal effect against the pathogen in comparison to brown propolis. Findings from the study indicated that a 2.5% dose of green propolis led to a 33.67%, 43.90%, and 43.23% inhibition in colony development at 48, 72, and 96 hours after inoculation, respectively; these values were higher in comparison to the inhibition rates of brown propolis at same dose. In the study, both propolis were tested using strawberry fruit *in vivo* at both doses (Table 1).

Table 1. Some studies conducted under *in vivo* conditions against *Botrytis cinerea*

Treatment	Scope	Result / Effectiveness	Author (Year)
Application of propolis ethanol extract (5 mg/ml) to eggplant leaves and cucumber fruits at different times before and after inoculation [dropping of conidia suspension (1×10^6 conidia/mL) into wounds opened on leaves and fruits] of the pathogen	Determination of the effect of application time (both 24, 48 hours before and after inoculation) on the growth of <i>B. cinerea</i>	The treatments made 24 and 48 hours before inoculation significantly slowed down disease development.	Darweesh (2010)
Spraying of a conidia suspension of the pathogen at a concentration of 1×10^5 conidia/mL after one minute immersion of strawberry fruits in solutions of green and brown propolis at 0.5% and 2.5% doses	Control of pathogen development in the cultivar (cv) Camarosa with different propolis doses	No difference was observed between the two propolis extracts in terms reducing disease incidence, with an overall inhibition rate of 12.5% being determined. The 0.5% dose of green propolis inhibited the disease severity at the highest rate (23.08%).	Moura et al. (2016)
After covering cherry tomatoes with pullulan film containing propolis ethanol extract (5% and 10%), the inoculation of the pathogen conidia suspension (10 µl) to the wound	Determining the protection of the application by measuring the pathogen population on tomatoes	There was no reduction in the population of coated pathogens after 14 or 21 days.	Pobiega et al. (2020)
Inoculation of pathogen (10 µL) into wounds opened	Evaluation of the effect of different propolis	In the study, after 15 days, Portuguese propolis	Diallo (2021)

with a pipette tip after immersing grapes berries in propolis solutions (15 g/L) for 2 minutes (min)	types (Portuguese, Brazilian red) on the decay area caused by <i>B. cinerea</i>	(~16.3%) was found to be effective in red grapes and Brazilian red propolis in white grapes (~21.5%) were found to be effective, even if at low rates.	
Treatment	Scope	Result / Effectiveness	Author (Year)
Immersion of strawberry fruits in propolis extract (20-, 40- and 60-mL/L) for 30 da, keeping at 25°C for 24 hours and inoculation of conidia suspension of the pathogen	Monitoring the rate of disease incidence at different times (24, 48, 72 hours), determining the PAL (phenylalanine ammonia-lyase) enzyme activity and total phenolic substance amount, which play a role in resistance	No significant decrease in disease incidence was observed at any time point at any of the three doses, and an increase was observed at higher doses. Although the total phenol content of the fruit decreased, PAL enzyme activity increased by only 7.61% after 72 hours.	Stefanski et al. (2024)
Inoculation of 5µl of conidia suspension of the pathogen into the fruits using a sterile needle; for volatile compounds, the placement of the inoculated fruits on sterile papers with 100 µl of extract; for non-volatile compounds, treating the extracts (5 µl) to the wounds on the fruit arranged on the grid one hour after inoculation.	Evaluation of the effect of volatile and non-volatile compounds in extracts on disease incidence	PFvg1 extract exhibited strong antifungal activity (~60-80%) for both compounds. PFvg2 followed it.	Sadallah et al. (2025)

Pobiega et al. (2020) determined the minimum inhibitory concentration (MIC) value for *B. cinerea* as 2 mg/mL and the minimum fungicidal concentration (MFC) value as 8 mg/mL as a result of serial dilution tests prepared with propolis ethanol extract (EEP). In the conducted study, additionally, pullulan films containing 5% and 10% EEP were prepared, and 6 mm diameter discs were cut from these films and placed on Sabouraud agar media spread with conidia suspension. Cellulose discs coated with EEP at the same concentration have been used as the control group. The experimental findings revealed that no inhibition zones were observed in any of the treatment groups. The *in vivo* tests of the study were carried out on cherry tomato fruits (Table 1).

In a study performed by Diallo (2021), the antifungal effects of three distinct propolis ethanol extracts (Portuguese propolis, Brazilian green propolis, and Brazilian red propolis) on *B. cinerea* G3 isolate were investigated. For the present study, the extracts were prepared at doses of 0.5 g/L, 1.5 g/L, 5 g/L, and 15 g/L, and were compared with a commercial fungicide and a fungicide containing the active ingredient tebuconazole. Both agar disk diffusion and well diffusion methods were used in the *in vitro* experiments. In the disk diffusion assay, square dishes containing 50 mL of PDA were prepared, and a conidial suspension with a density of 1×10^6 conidia/mL was spread evenly onto the

medium using a sterile swab. Subsequently, a total of nine filter paper disks were placed on the surfaces, and 100 µL of the extract was dropped onto each disk. In the well diffusion method, the same volume (100 µL) of solution was applied to each well (nine wells punched with the back of a sterile Pasteur pipette on the agar) and the experiments were conducted separately for different extracts. The dishes were then subjected to an incubation process at a temperature of 25°C for a period of five days. Following the conduction of the experiments, it was reported that none of the propolis species examined in both methods demonstrated antifungal efficacy at the applied doses. *In vivo* tests were conducted utilising extracts at a concentration of 15 g/L and grape berries. (Tablo 1).

Stefanski et al. (2024) examined the effects of an ethanol extract of brown propolis on mycelial development, sporulation and conidia germination of *B. cinerea* under *in vitro* and *in vivo* conditions. In the *in vitro* experiments, propolis extract was added to PDA medium at doses of 20, 40, and 60 mL/L. Petri dishes with a 5 mm diameter *B. cinerea* mycelium disk placed in the center were then incubated at 25°C for 6 days. Colony growth was measured daily, and conidia counts were performed at the conclusion of the sixth day. In the study, it was indicated that mycelial growth rates were significantly reduced and that sporulation was absent at doses of 40 and 60 mL/L. *In vivo* studies on strawberry fruits demonstrated that the three doses were ineffective in reducing disease incidence (Table 1.).

Sadallah et al. (2025) evaluated the antifungal activity of propolis samples [PFvg1 (Friuli Venezia Giulia), PFvg2 (Friuli Venezia Giulia), PU3 (Umbria), PV4 (Veneto), PT5 (Tuscany)] obtained from different geographical coordinates of various Italian regions against *B. cinerea* isolate obtained from grape berries, both *in vitro* and *in vivo* (Table 1). In the study, samples of propolis were prepared by extraction with a range of solutions of ethanol (30%, 60% and 90% v/v). *In vitro* tests were carried out in which the conidia suspension of the pathogen (1×10^5 conidia/mL) was spread on PDA medium, 80 µL of extract was applied to the wells (5 mm in diameter) on the medium, and the inhibition zones were measured after 72 hours. The findings of this test demonstrated that the widest inhibition zone was observed in the use of PU3 propolis extract, which was prepared with 90% ethanol. The researchers also had ascertained the EC₅₀ value for volatile and non-volatile compounds of each extract based on conidia germination using increasing doses (0, 3.2, 6.5, 12.5, 25, 50, 100, 150 and 200 ppm) of propolis extracts obtained by sonication with 90% ethanol for 24 hours. For tests involving volatile compounds, filter papers were placed on conidia suspensions spread on PDA medium, and the relevant dose of propolis extract was applied to each. For non-volatile metabolites, volatile compounds (100 µl) were added one hour after the pathogen spread onto the medium. Petri dishes were subjected to an incubation process at a temperature of 20°C for a duration of 48 hours. The outcomes of these experimental tests had indicated that PFvg2 (EC₅₀: 1.36 mg/ml) was identified as the most effective extract in regard to volatile compounds, while PU3 (EC₅₀: 2.24 mg/ml) was determined to be the most effective extract in relation to non-volatile compounds. In *in vivo* tests, the EC₅₀ value of each extract was used as the dose.

CONCLUSION

The *in vivo* studies referenced in this review demonstrate the significant antifungal potential of propolis extracts against *B. cinerea*. However, the extent of this efficacy is dependent on numerous factors, including the chemical composition of the propolis, the extraction method, the type of solvent utilised, the dose, the timing of application and the target plant tissue. The extant literature reveals that research studies have examined the efficacy of propolis extracts on the plants at post-harvest stage, with promising results obtained. The efficacy of propolis under *in vivo* conditions has been proven by significant reductions in disease incidence and lesion development, particularly in high-value crops

with perishable properties, including strawberries, grapes, blueberries, cucumbers and tomatoes. The fact that propolis is not only used in the context of agricultural products but also in human health, with its antimicrobial, antioxidant and anti-inflammatory properties, renders it a versatile and safe product. In this context, the utilisation of propolis, a substance that has been demonstrated to be effective in both human health and in the inhibition of plant pathogens, particularly in the control of fungal diseases in the post-harvest period in fruits, will not only result in a reduction of product loss but also contribute to food safety by eliminating the risk of chemical residues. In conclusion, propolis extracts, with their naturality, environmentally friendly composition, and multiple biological activities, have the potential to become a significant component of sustainable agricultural practices in the future to control postharvest diseases. However, further studies on various fruits and vegetables are needed to integrate this potential into agricultural practice.

ABSTRACT

Dairy cows in early postpartum experience significant metabolic stress that increases their susceptibility to mastitis. This study examined the correlation between mastitis pathogens and the activity of superoxide dismutase (SOD) and glutathione peroxidase (GPX) in blood serum. Over a two-year study, udder health and antioxidant enzyme activity were assessed across three physiological periods, from the 21st day before calving up to the 42nd day of lactation. During the trial period, each cow in lactation was observed daily for clinical signs of mastitis. Categorisation of the observed population was done following screening for mastitis using udder clinical examination, the California Mastitis Test, and bacteriological culturing. The measurement of the SOD and GPX activity in blood serum was done with spectrophotometric assays expressed as mU/mg protein. Mastitis pathogens were isolated from 43.83% of udder quarters with milk secretion disorder, and the dominantly isolated microorganisms were grouped as contagious: *Streptococcus agalactiae* (19.14%) and *Staphylococcus aureus* (6.17%) or environmental: *Enterococcus spp.* (8.02%), *Pseudomonas aeruginosa* (7.41%), *Escherichia coli* (1.85%) and *Aspergillus niger* (1.23%). The results indicated that contagious mastitis pathogens had a statistically significant influence on the SOD and GPX activity in the blood serum of transition dairy cows. The relationship between oxidative stress, anti-oxidative enzymes, and mastitis in dairy cows underscores the importance of managing oxidative levels to enhance udder health and prevent mastitis.

Keywords: dairy cows, antioxidative enzymes, mastitis.

INTRODUCTION

The oxide-reduction process in animal organisms is an essential biochemical phenomenon underpinning energy production, detoxification, and signalling. In animal cells, reduction reactions occur predominantly in the mitochondria, where oxygen is sequentially reduced to water through the electron transport chain. At the final step, the enzyme cytochrome c oxidase catalyses the reduction of oxygen, a process that is critical for ATP synthesis and overall cellular energy metabolism (Schieber & Chandel, 2014). Simultaneously, a balance is maintained between oxidation and reduction reactions to prevent the buildup of reactive oxygen species (ROS), thereby protecting cells from oxidative damage (Mladenov et al., 2023). Furthermore, the interplay between reductive and oxidative processes is not only central to metabolic functions but also plays a role in redox signalling. This redox balance is vital, since oxidative stress can lead to cellular dysfunction if not tightly regulated. These

mechanisms are intricately regulated through enzyme-catalysed pathways that maintain redox homeostasis, thereby protecting cells from damage while allowing necessary physiological functions to proceed effectively (Schieber & Chandel, 2014).

Oxidative stress in animal systems is a phenomenon that results from an imbalance between reactive oxygen species (ROS) production and the capacity of antioxidant defences. This imbalance can damage cellular proteins, lipids, and nucleic acids, thereby contributing to various physiological and pathological conditions in animals. When ROS levels exceed the buffering capacity of endogenous antioxidants, oxidative damage occurs, which can disrupt normal cellular function and lead to disease states (Sies, 2015).

Dairy cows, particularly during the peripartum period, exhibit significantly increased oxidative stress levels due to metabolic disturbances, which predispose them to intramammary infections and subsequently mastitis (Turk, 2017).

The most significant connection between oxidative stress and mastitis lies in the inflammatory response. During mastitis, the immune system responds to bacterial invasion by releasing inflammatory mediators and immune cells that produce reactive oxygen species (ROS) as a defence strategy. Although this helps fight infection, an overproduction of ROS can lead to oxidative stress, resulting in tissue damage and amplified inflammation. This harmful cycle can impair immune function, making the cow more vulnerable to further infections. Increases in oxidative products such as malondialdehyde (MDA), an indicator of lipid peroxidation, have been observed in cows with mastitis, reinforcing the notion that these oxidative markers correlate with the severity of the disease (Rizzo et al., 2013; Mavangira et al., 2015). Studies indicate that bacterial endotoxins increase the expression of pro-inflammatory cytokines in mammary tissues, which can elevate oxidative stress levels (Guo et al., 2020). Different mastitis pathogens may elicit varying responses in terms of oxidative stress and antioxidative enzyme activity.

The primary objective of this study was to establish a connection between mastitis pathogens and oxidative stress through the activity of SOD and GPX in blood samples collected from dairy cows during the transition period from late gestation to early lactation.

MATERIAL AND METHOD

In this study, the activity of the antioxidant enzymes SOD (superoxide dismutase) and GPX (glutathione peroxidase) in the blood serum of dairy cows was used as a biomarker of oxidative stress.

During the study, the health status of the mammary gland in early-lactating cows and changes in antioxidant enzyme activity in blood serum were monitored to explore a potential relationship between enzyme activity and udder health.

The blood samples for determination of SOD and GPX activities were collected in three physiological periods (PP): the dry period 21 days before calving (transition period 21 - TP_21), the period from the beginning of lactation until the 21st day in lactation (lactation period 21 - LP_21) and the period from 22nd to 42nd day in lactation (lactation period 42 - LP_42). The methodology was described in detail in the previously published paper by Nakov et al. (2023).

During the trial period, each cow in lactation was observed daily for clinical signs of mastitis. The California Mastitis Test (CMT) was used to detect quarters with abnormal milk secretion. Milk

samples from CMT-positive quarters were aseptically collected for microbiological culturing, following National Mastitis Council guidelines (NMC, 2004). The isolated microorganism species were classified as either contagious or environmental pathogens. Based on clinical examination, CMT results, and bacteriological cultures, cows were categorised into four groups: healthy, those with persistent milk secretion disorder (MSD), and those with intramammary infection (IMI) caused by contagious or environmental pathogens.

The measurement of the SOD and GPX activity in blood serum was done with spectrophotometric assays expressed as mU/mg protein. SOD activity was measured using kinetic analysis according to Gao et al. (1998), while GPX measuring was used method modified according to Chen et al. (2000). The methodology was described in detail in the previously published paper by Nakov et al. (2023).

Multivariate General Linear Model (GLM) was used to determine the influence of mastitis pathogens on changes in SOD and GPX activity in blood serum.

RESULTS AND DISCUSSION

The prevalence of udder health disorders on quarter level, in the observed population of dairy cows in early lactation during the two-year survey is shown in Table 1.

Table 1. The prevalence of udder health disorders in dairy cows on the quarter level in PP of early lactation

LP	Total	CMT(-)		CMT(+)		MSD		IMI	
	n	n	%	n	%	n	%	n	%
21	844	765	90,64	79	9,36	45	5,33	34	4,03
42	844	761	90,17	83	9,83	46	5,45	37	4,38

Graph 1 represents the distribution of udder pathogens in milk samples from udder quarters with MSD that showed a positive reaction to CMT.

Graph 1. Udder pathogens isolated in milk sample from quarters with positive CMT

Mastitis pathogens were isolated from 43.83% of udder quarters with MSD, and the dominantly isolated microorganisms were grouped as contagious: *Streptococcus agalactiae* (19.14%) and *Staphylococcus aureus* (6.17%) or environmental: *Enterococcus spp.* (8.02%), *Pseudomonas aeruginosa* (7.41%), *Escherichia coli* (1.85%) and *Aspergillus niger* (1.23%).

Given that IMIs typically trigger an influx of leukocytes and other macrophages into milk, an elevated SCC has been extensively used as an indicator of mastitis. While higher CMT scores generally indicate increased SCC levels, the accuracy of CMT or SCC in reflecting pathogen-specific IMIs remains uncertain (Dingwell et al., 2003). The concordance between CMT results and bacteriological findings ranges from 70 to 86%, varying with the causative agent (Sanford et al., 2006).

The changes in the activity of antioxidant enzymes SOD and GPX in three PP from late gestation to early lactation, related to udder health status are shown in Graphs 1 and 2.

Contagious mastitis pathogens have increased the average activity of SOD in blood, especially in LP_21. Environmental mastitis pathogens did not increase SOD activity in blood compared to mastitis-free cows and those with MSD; instead, SOD activity was reduced.

As shown in Graph 2, the average GPX activity was higher in the blood of cows with IMI caused by contagious mastitis pathogens. The charts indicate that SOD and GPX activity in blood is increasing when IMI caused by major mastitis pathogens is existing.

The escalated activity of SOD and GPX observed in the period after parturition was probably a consequence of the increased synthesis of ROS triggered by the immune response to mastitis pathogens. Previously published paper indicates that the transition period in dairy cows has a statistically significant influence ($p < 0.001$) on SOD and GPX activity in blood serum (Nakov et al., 2023). This imbalance in antioxidant enzyme activity increases the risk of oxidative stress during this critical period.

Graph 1. Average activity of SOD (mU/mg proteins) in blood serum related to the health status of cows' mammary gland

Graph 2. Average activity of GPX (mU/mg proteins) in blood serum related to the health status of cows' mammary gland

***Significant at level $p < 0.001$;

The results indicated that the presence of mastitis pathogens in the milk during the period of early lactation has a statistically significant influence ($p < 0.001$) on the SOD and GPX activity in the blood serum of transition dairy cows. When mastitis afflicts a dairy cow, whether clinical or subclinical, the immune system responds to the invading pathogens (usually bacteria) by releasing various inflammatory molecules and immune cells. Moreover, inflammation and oxidative stress appear to mutually influence each other in the context of mastitis, ultimately fostering a vicious cycle where inflammation leads to increased oxidative stress, which in turn further intensifies inflammation (Turk, 2017). This immune response generates ROS as a part of the body's defence mechanism to eradicate pathogens. Different pathogens may elicit varying responses in terms of oxidative stress and antioxidative enzyme activity (Erisir et al., 2006; Kleczkowski et al., 2008). To counterbalance the potentially harmful effects of ROS, cows have antioxidative defence mechanisms in place. Antioxidative enzymes SOD, GPX and CAT help neutralize ROS and maintain a balanced oxidative state within the body. These enzymes play a crucial role in protecting cells and tissues from oxidative damage. Because SOD activity increases the production of hydrogenated peroxides by dismutation of superoxide, protection against ROS would be achieved only with the increased GPX activity and hydrogenated peroxides reduction (Maurya et al., 2014). The increased activity of antioxidant enzymes in dairy cows that have mastitis in the period of early lactation may indicate that oxidative stress is exacerbated. Elevated somatic cell counts (SCC), which are indicative of mastitis, have also been correlated with increased oxidative stress markers, emphasizing the detrimental effects that oxidative stress has on udder health (She et al., 2023).

CONCLUSIONS

In dairy cattle, oxidative stress is a critical factor during transition periods like parturition and lactation. During these phases, metabolic demands intensify, leading to altered redox status; consequently, imbalances between oxidant and antioxidant systems can predispose animals to metabolic and infectious diseases. The relationship between oxidative stress, anti-oxidative enzymes, and mastitis in dairy cows underscores the importance of managing oxidative levels to prevent mastitis. Nutritional interventions and management practices that bolster antioxidant defences may be an essential strategy to mitigate oxidative damage and improve udder health, dairy production and animal welfare.

ABSTRACT

Monitoring root systems and their associated rhizosphere microbiomes is critical for advancing sustainable agriculture and understanding plant-microbe interactions. Traditional microrhizotron systems rely on rigid transparent tubes and fixed cameras, which restrict flexibility and often limit imaging angles. We propose two novel wearable glove-based designs that address these limitations by enabling non-destructive, in situ root and microbial rhizosphere detection with enhanced mobility and spectral sensing capabilities. The first design integrates a 360° hyperspectral camera controlled by miniaturized geared stepper motors mounted on a wearable glove, allowing dynamic panoramic imaging around root zones. The second design employs Contact Image Sensors (CIS) embedded along the glove's palm and fingers for high-resolution, direct-contact scanning of root surfaces and biofilms. This conceptual design paper presents the architecture, components, expected functionality, and potential agricultural and research applications of these gloves. We also discuss their complementary phenotypic differences, limitations, and future prototyping plans.

INTRODUCTION

Roots and their surrounding rhizosphere host complex microbial communities that profoundly influence plant health and soil fertility. Non-invasive monitoring of these underground interactions is vital for advancing precision agriculture, biofertilizer evaluation, and plant breeding. Microrhizotrons, transparent tubes inserted into soil to observe roots and microbes, have long been used but are constrained by fixed cameras and limited viewing angles. Recent advances in wearable sensing technologies suggest that a ****glove-based microrhizotron system**** could provide unprecedented flexibility and real-time root phenotyping. Here, we present two independent conceptual designs for such a system: (1) a glove equipped with a geared stepper motor-controlled 360° hyperspectral camera and (2) a glove embedded with Contact Image Sensors (CIS). Both aim to facilitate non-destructive, multi-scale root and rhizosphere imaging.

Related Work

Microrhizotron systems traditionally utilize rigid transparent tubes with fixed or movable cameras to capture root images (Nagel et al., 2012). However, their limited mobility and fixed viewing geometry restrict phenotyping flexibility. Hyperspectral imaging has been applied in root phenotyping to detect biochemical and structural changes (Behmann et al., 2015), but integration into wearable devices remains unexplored.

Contact Image Sensors (CIS) have been used in document scanning and recently adapted for plant surface scanning (Smith et al., 2020). Combining hyperspectral imaging with wearable sensors could

bridge the gap between remote sensing and direct contact phenotyping. Our designs are inspired by stepper motor-driven microrhizotron camera systems (e.g., [PMC7038518](https://pmc.ncbi.nlm.nih.gov/articles/PMC7038518/)) and advances in flexible sensor integration.

Design Concept

Design 1: Geared Stepper Motor-Controlled 360° Hyperspectral Camera Glove

This design features a miniaturized 360° hyperspectral camera mounted on the glove's palm or fingertip. Miniature geared stepper motors housed in the wrist or cuff control rotational motion of the camera probe, enabling dynamic scanning of root zones from multiple angles (figure 1).

- (i) Camera Specs: Hyperspectral module covering 400–1000 nm wavelengths, capable of detecting biochemical signatures such as flavonoids, chlorophyll, and microbial metabolites.
- (ii) Stepper Motors: Low-torque geared stepper motors provide precise angular control, allowing panoramic scanning.
- (iii) Data Handling: Wireless transmission to a handle device or cloud storage for real-time processing.
- (iv) Power: Compact rechargeable battery embedded in the glove cuff.

Design 2: Contact Image Sensor (CIS) Embedded Glove

The second design integrates linear CIS arrays along the glove's palm and fingers, enabling direct-contact scanning of root surfaces and microbial biofilms.

- (i) Sensors: RGB+NIR CIS arrays similar to document scanners, providing high spatial resolution line scanning.
- (ii) Operation: User moves the glove across transparent rhizobox surfaces or accessible root exposures.
- (iii) Spectral Range: Limited compared to hyperspectral cameras but sufficient for detecting surface features and pigment changes.
- (iv) Data Collection: Continuous scanning with onboard microcontroller; data streamed wirelessly.

Technical Details

Component Selection

Unraveling the complexity of root phenotyping demands tools that can capture both spatial and biochemical intricacies with high precision. Design 1 exemplifies this by integrating a motorized system capable of rotating the hyperspectral camera with an angular resolution of approximately 1° and a scan speed of 10° per second, enabling rapid, comprehensive 360° coverage of the rhizosphere. Its spectral resolution of about 5 nm facilitates the detection of subtle physiological and biochemical shifts in root and microbial tissues, offering a three-dimensional hyperspectral map that bridges structural and functional insight (table 1). Such granularity empowers researchers to monitor dynamic microbial colonization and root stress responses with unprecedented detail (Ustin et al., 2004 ; Behmann et al., 2015 ; Walter et al., 2015).

In contrast, Design 2 leverages a Contact Image Sensor with a high spatial resolution of 600 dpi along a linear scan width of roughly 5 cm. Though spectrally limited to broad RGB and near-infrared bands, its simplicity, extended battery life of approximately 3 hours, and portability render it ideal for rapid surface phenotyping and microbial film detection in transparent rhizoboxes. Together, these technologies represent a complementary spectrum of phenotyping tools: one delivering depth through rich spectral and angular resolution, the other breadth through ease of use and extended operational duration. Collectively, they herald new possibilities for scalable, field-adapted root phenotyping that can accelerate advances in plant-microbe research and sustainable agriculture (Fiorani & Schurr, 2013 ; Wasson et al., 2020).

Both designs interface wirelessly with smartphones or tablets running custom apps for real-time visualization, spectral analysis, and data logging. The stepper motor glove supports gesture controls for scanning commands.

Table 1 : Component-level comparison of two wearable root imaging glove designs

Component	Design 1 (Stepper + Camera)	Design 2 (CIS Glove)
Imaging Sensor	Mini hyperspectral camera (400–1000 nm)	RGB + NIR Contact Image Sensor Arrays
Motion Control	Miniature geared stepper motors	Manual hand motion
Processing Unit	ESP32 microcontroller or similar	Low-power MCU for line scan processing
Power Source	Rechargeable Li-ion battery (cuff)	Small rechargeable battery or tethered
Wireless Communication	Wi-Fi or Bluetooth module	Bluetooth Low Energy (BLE)
Lighting	Integrated LED excitation for fluorescence	External or integrated LED strips

Comparative Phenotypic Analysis

To clearly differentiate the two glove designs, Table 1 presents a detailed phenotypic comparison across key parameters including imaging mode, spectral range, resolution, power consumption, and application suitability (table2)

Table 2 : Functional and performance-based comparison of hyperspectral and CIS glove systems for root phenotyping

Category	Parameter	Design 1: Stepper Motor + 360° Hyperspectral Camera	Design 2: Contact Sensor (CIS) Image Glove
Optical Performance	Spectral Range	Broad hyperspectral: 400–1000 nm (visible to near-infrared), ± 5 nm spectral resolution [1]	RGB + NIR bands (~400–900 nm), limited spectral resolution (~10 nm) [2]
	Spatial Resolution	~50–100 $\mu\text{m}/\text{pixel}$ (depends on optics and sensor size)	High: ~10–20 $\mu\text{m}/\text{pixel}$ (scanner-grade linear sensor)
	Field of View (FOV)	Full 360° rotation enabling panoramic scanning of roots	Linear line scan ~5 cm width per pass
	3D Imaging Capability	True 3D surface mapping via motorized rotation	2D imaging only; 3D reconstruction possible by stitching multiple scans
	Fluorescence Imaging Potential	High; excitation LEDs and filters can be integrated	Limited; depends on CIS sensitivity and additional illumination
Mechanical & Power	Mobility & Wearability	Moderate; motors and battery add weight and bulk (~250 g estimate)	High; lightweight (~100 g), low power consumption
	Power Consumption	Higher (~2–3 W continuous operation for motors + camera)	Low (~0.5 W), suitable for extended scanning sessions
	Data Acquisition Speed	Slower; full 360° scan in 30–60 s depending on stepper speed	Fast; real-time line scans during manual movement
	Operational Environment	Suitable for structured rhizoboxes and controlled soil cores	Best for transparent rhizoboxes or accessible root surfaces
	Durability & Robustness	Moderate; mechanical parts sensitive to dust/moisture, requires casing	High; solid-state sensors easier to protect and maintain
Data & Processing	Data Volume & Complexity	High; hyperspectral data generates large files (100s MB per scan)	Moderate; line scans generate smaller data (~MB scale)
	Processing Requirements	Advanced spectral unmixing and machine learning needed	Simpler image processing; color and NIR analysis

User Interaction	Calibration Needs	Frequent spectral and motor calibration necessary	Lower; mainly sensor calibration
	Wireless Connectivity	Wi-Fi/Bluetooth; real-time streaming possible	Bluetooth Low Energy (BLE); low latency streaming
	Ease of Use	Moderate; requires motor control interface (app or gestures)	High; intuitive manual scanning
	Training Required	Medium; user needs to understand motorized scanning	Low; natural hand movements sufficient
Cost & Scalability	Estimated Cost	High; hyperspectral cameras and motors cost \$2000–5000+	Moderate; CIS sensors and microcontrollers ~\$500–1000
	Scalability for Field Use	Challenging; power and mechanical complexity	Easy; low power and simple design suited for wide deployment
Application Suitability	Key Strengths	Multi-angle biochemical root phenotyping, microbial metabolite detection	High-resolution root surface imaging, biofilm and exudate detection
	Limitations	Bulkier design, limited soil ruggedness	Limited spectral range, requires accessible surfaces

Use Cases

- Precision Agriculture: Early detection of root pathogens, monitoring biofertilizer colonization, and drought stress via root spectral signatures.-
- Research: Phenotyping root architecture and microbiome dynamics in transparent rhizoboxes and soil cores.
- Education: Hands-on tool for plant biology classes to visualize underground root processes.
- Biofertilizer Development: Tracking mycorrhizal colonization efficiency on roots in situ.

Advantages and Limitations (table 3 below)

Design	Advantages	Limitations
Stepper-Motor + 360° Hyperspectral Camera Glove	• Non-destructive, in-situ imaging of root zones. • Panoramic (360°) scanning around roots for true 3-D mapping. • Captures biochemical/spectral signatures (stress, metabolites). • Custom-configurable scan speed and spectral bands. • Real-time data streaming and AI-ready datasets. • Suited to structured systems (rhizoboxes, root tubes).	• High component cost (hyperspectral sensor + motors). • Bulkier; reduced hand mobility and comfort. • Dust/moisture sensitive; needs protective casing. • Power-hungry; battery life < 2–3 h continuous use. • Requires regular camera/motor calibration. • Large hyperspectral files demand heavy processing/storage. • Less practical in loose, unstructured field soils. • Must touch root or clear surface—no remote imaging. • Limited spectral range (RGB + NIR only). • Ineffective in opaque soil or deep root tubes. • Sensor can foul from soil debris/exudates. • Scan quality depends on steady manual motion. • No inherent 3-D capability (requires post-processing). • Less sensitive to subsurface microbial activity.
Contact Image Sensor (CIS) Glove	• Lightweight, highly wearable; full finger dexterity. • High-resolution surface scans ($\approx 10\text{--}20\text{ }\mu\text{m/pixel}$). • Low power; extended battery life. • Lower cost; uses off-the-shelf CIS arrays. • Simple to operate; minimal user training. • Immediate visual feedback via phone/tablet. • Ideal for quick phenotyping in transparent rhizoboxes.	

CONCLUSION

We present two complementary conceptual designs for wearable 3D gloves capable of hyperspectral and contact imaging of root systems and rhizosphere microbes. By combining advanced sensors with wearable mobility, these devices promise flexible, non-invasive phenotyping tools that overcome limitations of current microrhizotron systems. This work lays the foundation for novel, user-friendly technologies to support sustainable agriculture and plant science research.

ABSTRACT

Greenhouse gas (GHG) emissions are among the primary causes of global warming and climate change. Gases such as carbon dioxide (CO₂), methane (CH₄), and nitrous oxides (N₂O) originate from human-induced activities, including fossil fuel consumption, industrial processes, agriculture, and deforestation. The accumulation of these gases in the atmosphere leads to rising temperatures, glacier melting, sea level rise, and an increase in extreme weather events.

This study explores various solutions to mitigate greenhouse gas emissions. Transitioning to renewable energy sources, such as solar, wind, and hydroelectric power, enhancing energy efficiency, promoting the widespread adoption of electric and hybrid vehicles in transportation, implementing sustainable agricultural practices, and initiating forest conservation projects are among the key strategies. Additionally, carbon capture and storage (CCS) technologies, alongside changes in individual consumption habits such as opting for low-carbon footprint products and increasing recycling efforts play a crucial role in reducing emissions.

Keywords: Greenhouse gas, global warming, industrial process, renewable energy

INTRODUCTION

Greenhouse gas (GHG) emissions represent one of the most critical environmental issues confronting the 21st century. This study investigates the ecological consequences associated with GHG emissions and evaluates a range of mitigation strategies aimed at reducing their impact. Particular focus is directed toward carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O), which constitute the primary anthropogenic greenhouse gases. The paper further discusses sustainable mitigation approaches, such as the deployment of renewable energy sources, enhancement of energy efficiency, implementation of carbon capture technologies, and large-scale reforestation efforts (Chen et al., 2023).

Greenhouse gases contribute to the retention of heat within the Earth's atmosphere, thereby exacerbating the greenhouse effect and elevating global temperatures. Although this natural phenomenon is vital for sustaining life on Earth, anthropogenic emissions have significantly amplified its intensity, culminating in global warming and widespread climate disruption. Key drivers of GHG emissions include industrial processes, deforestation, and agricultural practices (Jensen et al., 2023). The resulting rise in global temperatures has led to an increase in the frequency and severity of heatwaves, as well as accelerated polar ice melt and thermal expansion of ocean waters, collectively contributing to sea level rise and heightened flooding risks (Aghakouchak et al., 2020).

Additionally, coastal marine ecosystems are increasingly threatened by anthropogenic activities, such as industrialization, agriculture, land-sea based aquaculture, and climate change. These pressures have led to coastal eutrophication, which is a major driver of macroalgal blooms (Smetacek and Zingone, 2013).

Macroalgal bloom events—such as green and golden seaweed tides—induce profound shifts in both the physical and biogeochemical characteristics of the water column, thereby exerting considerable influence on greenhouse gas (GHG) emissions. Empirical evidence indicates that microalgal blooms can markedly decrease atmospheric carbon dioxide (CO₂) concentrations as a result of intensified photosynthetic activity. Concurrently, these events often stimulate the production of nitrous oxide (N₂O) and methane (CH₄), primarily through mechanisms involving the degradation of particulate organic matter (POM) and the emergence of hypoxic or anoxic conditions within marine systems (Cai et al., 2024).

The accelerating pace of climate change continues to pose serious threats to both human and ecological health (Romanello et al., 2022). In response to this escalating crisis, achieving the targets outlined in the Paris Climate Agreement and the Kigali Amendment to the Montreal Protocol necessitates a substantial and immediate reduction in global greenhouse gas emissions (Intergovernmental Panel on Climate Change, 2023).

According to estimates by the Food and Agriculture Organization of the United Nations (FAO), emissions from the agricultural sector account for approximately 30% of total global greenhouse gas (GHG) emissions. The predominant greenhouse gases emitted from agricultural soils include carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O) (Chataut et al., 2023).

In agricultural systems, both natural factors—such as soil moisture, temperature, and pH—and anthropogenic farming practices exert significant influence over the magnitude of GHG emissions. A wide body of research has investigated various strategies to mitigate these emissions. One promising approach involves the development and cultivation of crop varieties with enhanced capacities for carbon and nitrogen uptake. Such improvements can increase the efficiency of nutrient use, reduce

dependence on synthetic fertilizers, and consequently decrease GHG emissions (Johansson et al., 2023).

Furthermore, optimizing fertilization practices—including the timing, quantity, and type of fertilizers applied—has been demonstrated to be an effective measure for controlling greenhouse gas emissions associated with agricultural activities (Li et al., 2023).²

Environmental Impacts of Greenhouse Gas Emissions

Climate Change and Global Warming

The most direct and severe consequence of GHG emissions is global warming. Average global temperatures have increased significantly since the industrial revolution, resulting in more frequent and intense heatwaves, droughts, and wildfires.

Climate change refers to long-term shifts and alterations in temperature, precipitation patterns, wind, and other elements of the Earth's climate system. Global warming, on the other hand, is the rise in the average surface temperature of the Earth due to increasing concentrations of greenhouse gases in the atmosphere (Koch et al., 2013).

Causes of Global Warming

The primary cause of global warming is human activity, particularly the burning of fossil fuels such as coal, oil, and natural gas. These activities release large amounts of greenhouse gases (especially carbon dioxide – CO₂, methane – CH₄, and nitrous oxide – N₂O) into the atmosphere. Other contributing factors include:

- Deforestation, which reduces the planet's capacity to absorb CO₂.
- Industrial processes that emit large quantities of GHGs.
- Agriculture, especially livestock farming which releases methane.
- Waste management practices that lead to the release of methane and other gases (Holgerson and Raymond, 2016).

Melting Ice Caps and Rising Sea Levels

The warming climate causes glaciers and polar ice caps to melt, contributing to rising sea levels. This threatens coastal ecosystems and human settlements, especially in low-lying countries and island nations.

One of the most visible and alarming consequences of global warming is the accelerated melting of polar ice caps and glaciers. This process directly contributes to rising sea levels, which pose serious threats to both natural ecosystems and human settlements, particularly in coastal and low-lying areas (Ren et al., 2020).

The treason of the melting of the ice caps can be described as; global temperatures rise. This means, Arctic sea ice is shrinking, especially during summer months. Land-based ice sheets and glaciers, such as those in Greenland and Antarctica, are losing mass rapidly. Melting land ice flows into oceans, increasing sea levels. Thermal Expansion means ocean temperatures increase, seawater expands. This thermal expansion accounts for nearly half of the observed sea level rise over the past century. Unlike sea ice, land-based ice adds new water to the ocean when it melts. The vast ice sheets in Greenland and Antarctica are currently the largest contributors to sea level rise from melting ice (Xie et al., 2021).

Current and Future Threats

Coastal Cities at Risk: Major urban areas like New York, Miami, Jakarta, Mumbai, and Istanbul face increased flooding and infrastructure damage. Saltwater intrusion can also contaminate freshwater supplies and damage agriculture.

Small Island Nations in Danger: Countries such as the Maldives, Tuvalu, and Kiribati are threatened with complete submersion if sea levels continue to rise, potentially creating the world's first "climate refugees."

Coastal Erosion and Habitat Loss: Rising seas accelerate erosion, submerge wetlands, and destroy mangroves and other critical coastal ecosystems.

Climate Migration: As coastal regions become uninhabitable, millions may be forced to migrate inland, leading to social, economic, and political challenges (Liu et al., 2021).

Scientific Projections: Over the 20th century, sea levels rose by approximately 15–20 centimeters (6–8 inches).

According to the Intergovernmental Panel on Climate Change (IPCC), sea levels are projected to rise by 0.6 to 1.1 meters (2 to 3.6 feet) by 2100 if greenhouse gas emissions continue at current levels.

Solutions and Adaptation Measures

Reducing greenhouse gas emissions can slow down global warming and ice melt. Coastal protection infrastructure, such as seawalls, flood barriers, and artificial islands, can help shield vulnerable areas. Climate adaptation policies must be developed, including strategic urban planning and relocation strategies for at-risk populations (Sheng et al., 2018).

Ocean Acidification

Excess CO₂ dissolves into oceans, lowering pH levels and disrupting marine ecosystems. Coral reefs, which are home to many marine species, are particularly vulnerable.

Ocean acidification refers to the ongoing decrease in the pH of the Earth's oceans, caused primarily by the uptake of carbon dioxide (CO₂) from the atmosphere. As anthropogenic CO₂ emissions have increased, a significant portion—approximately 30%—has been absorbed by the world's oceans. This

process has altered the chemical composition of seawater, posing severe risks to marine biodiversity, ecosystems, and human societies dependent on oceanic resources (Alcaraz-Rocha et al., 2023).

This sequence results in the formation of carbonic acid (H_2CO_3), which dissociates to release hydrogen ions (H^+), lowering the pH and increasing ocean acidity. As a consequence, the availability of carbonate ions (CO_3^{2-})—which are essential for marine calcifying organisms to form shells and skeletons—decreases.

Ecological Impacts

Coral Reef Degradation: Coral reefs are particularly sensitive to changes in pH. Ocean acidification weakens coral skeletons and inhibits reef growth, which in turn affects the vast array of marine life that depends on reef ecosystems for habitat and food (Hoegh-Guldberg et al., 2007).

Food Web Disruption: Many planktonic species form the foundation of marine food webs. The decline in their populations due to acidification can have cascading effects on higher trophic levels, including commercially important fish species (Yudhistira et al., 2023).

Impact on Marine Biodiversity and Fisheries: As marine ecosystems become destabilized, biodiversity loss is likely to accelerate. This endangers not only ecological balance but also the livelihoods of millions of people who rely on fisheries and aquaculture (Hollowed et al., 2013).

Socioeconomic Consequences

Food Security Risks: Communities that depend on shellfish and coral reef fisheries are particularly vulnerable to declining stocks and ecosystem collapse (Sovacool and Mukherje, 2011).

Economic Losses: The global seafood industry may face significant economic setbacks. Coral reef tourism, valued at billions of dollars annually, is also at risk (Kuznet, 2019).

Biodiversity Loss

Biodiversity loss refers to the decline or disappearance of biological diversity at the genetic, species, and ecosystem levels. As a result of anthropogenic climate change primarily driven by the emission of greenhouse gases (GHGs) natural habitats are increasingly subjected to environmental stressors that alter ecological balances, disrupt species interactions, and undermine ecosystem resilience. Among these stressors, rising temperatures, altered precipitation patterns, ocean acidification, and habitat degradation are particularly detrimental to biodiversity (Isbell et al., 2013).

Mechanisms of Biodiversity Loss Due to Climate Change

Habitat Alteration and Fragmentation: Shifts in temperature and precipitation can transform ecosystems, rendering them unsuitable for species that are highly specialized or geographically restricted. Alpine, polar, and coral reef ecosystems are especially vulnerable to these changes. Habitat

fragmentation also limits species' ability to migrate in response to changing environmental conditions (Liu et al., 2023).

Consequences for Ecosystem Functioning: Biodiversity plays a critical role in ecosystem stability, productivity, and the provision of essential services such as pollination, water purification, carbon sequestration, and soil fertility. Loss of species richness and genetic diversity can reduce an ecosystem's capacity to respond to environmental changes and recover from disturbances, increasing the risk of ecological collapse (Tong et al., 2019).

Agricultural Disruption

Agricultural disruption refers to the adverse effects of climate change on crop production, livestock systems, soil health, and overall agricultural productivity. As global temperatures rise and climatic variability intensifies, agriculture the foundation of global food security and rural economies faces multifaceted challenges. These include altered growing seasons, increased frequency of extreme weather events, changing precipitation patterns, and the proliferation of pests and diseases. Such disruptions threaten the stability of food systems, particularly in regions already vulnerable to environmental and socio-economic stressors (Rees et al., 2014).

Climatic Stressors Impacting Agriculture

Temperature Increases: Higher average temperatures can accelerate crop maturation, leading to reduced yields. Heat stress also negatively affects livestock health, reproduction, and productivity. For many staple crops such as wheat, rice, and maize, there is a critical threshold beyond which yields decline substantially (Ma et al., 2020).

Extreme Weather Events: More frequent and severe heatwaves, storms, and frosts can cause sudden and severe damage to crops and infrastructure. These events not only reduce agricultural output but also increase production costs and risks for farmers (Wohlfart et al., 2008).

Increased Pest and Disease Incidence: Rising temperatures and humidity create favorable conditions for the spread of pests, fungi, and crop diseases, which were previously confined to specific geographic regions. This increases the vulnerability of food systems and requires greater dependence on chemical inputs (Méndez-Bautista et al., 2009).

Soil Degradation: Changes in temperature and precipitation, along with intensive agricultural practices, contribute to soil degradation, reducing fertility and the capacity to support sustainable farming (Cruz et al., 2020).

Regional Disparities and Vulnerabilities: Developing countries, particularly those in tropical and subtropical regions, are more severely affected due to limited adaptive capacity, high dependence on rain-fed agriculture, and constrained access to technology and infrastructure. Smallholder farmers, who represent a large portion of the global agricultural workforce, face increased livelihood insecurity and food scarcity as a result of climate-induced disruptions (Jia et al., 2018).

Adaptation and Resilience Strategies

Climate-Smart Agriculture (CSA): CSA practices aim to sustainably increase productivity, enhance resilience (adaptation), and reduce greenhouse gas emissions. This includes crop diversification, agroforestry, conservation agriculture, and efficient water management (nazim et al., 2025).

Technological Innovation: The development and dissemination of drought-resistant and heat-tolerant crop varieties, precision farming technologies, and early-warning systems can support adaptation (Lybbert and Sumne, 2012).

Policy and Institutional Support: Governments and international organizations must invest in agricultural research, rural infrastructure, extension services, and risk insurance schemes to support vulnerable farming communities.

Integrated Land and Water Management: Holistic approaches that conserve natural resources and promote sustainable land use are essential to long-term agricultural resilience.

DISCUSSION AND CONCLUSION

Greenhouse gas emissions pose a critical threat to the environment and to human societies. However, through coordinated global action and the implementation of innovative solutions, their negative impacts can be mitigated. Transitioning to a low-carbon future is not only possible but necessary to ensure the health of the planet for future generations. Multiple factors influence the impact of flooding on greenhouse gas emissions, including soil type, water source, and flood duration.

Agricultural disruption is a critical dimension of climate change with profound implications for global food systems, rural livelihoods, and economic stability. Urgent and coordinated adaptation strategies are necessary to ensure the sustainability and resilience of agriculture in a warming world.

Replacing fossil fuels with renewable sources such as solar, wind, and hydropower is one of the most effective ways to reduce GHG emissions. Improving the energy efficiency of buildings, transportation, and industrial processes can significantly cut emissions while reducing energy costs.

CCS technology captures CO₂ from power plants and industrial sources and stores it underground, preventing it from entering the atmosphere. Trees absorb CO₂ through photosynthesis. Large-scale tree planting can act as a natural carbon sink, helping offset emissions. Practices such as crop rotation, reduced tillage, and efficient fertilizer use can lower emissions from agricultural activities, especially methane and nitrous oxide.

Global cooperation through agreements like the Paris Accord is essential. Governments should implement carbon pricing, subsidies for clean energy, and stricter emission regulations.

In conclusion, the reduction of greenhouse gas emissions should not be confined solely to measures taken by governments and large corporations; rather, it should be recognized as a global responsibility

in which individuals must also play an active role. While governments and businesses can make significant contributions by investing in renewable energy, enforcing strict environmental regulations, and implementing policies to limit carbon emissions, individuals can support this process by adopting eco-friendly habits in their daily lives. Key individual actions include conserving energy, opting for sustainable transportation methods, embracing recycling practices, making conscious consumption choices, and preferring products that minimize greenhouse gas emissions. In this context, the adoption of sustainable policies in both production and consumption, the promotion of innovative environmental technologies, and raising public awareness will be crucial in mitigating the devastating effects of climate change.

ABSTRACT

Global warming has emerged as a critical driver of change in freshwater ecosystems, exerting multifaceted influences on the physical, chemical, and biological characteristics of freshwater systems. Rising air temperatures cause to increase in surface water temperatures, which reduces the solubility of dissolved oxygen and intensifies thermal stratification, promoting hypoxic or anoxic conditions in deeper layers.. Enhanced evaporation rates and altered precipitation patterns exacerbate seasonal and annual fluctuations in water levels, concentrating contaminants and reducing the self-purification capacity of lotic systems. Concurrently, elevated runoff during extreme rainfall events transports greater loads of nutrients and associated agrochemicals into water bodies, fueling harmful algal blooms and promoting toxin production by cyanobacteria. Intensified drought periods further increase pollutant concentrations and facilitate the proliferation of invasive or opportunistic species, weakening local biodiversity and destabilizing trophic interactions. These changes collectively threaten aquatic ecosystem services, compromise drinking-water quality, and increase treatment costs, while also posing direct risks to human and animal health through exposure to algal toxins and waterborne pathogens.

This review synthesizes recent findings on the mechanisms by which climate warming is changing freshwater quality and identifies key knowledge gaps. Finally, it outlines adaptive management strategies such as enhanced monitoring networks, watershed-scale nutrient management, restoration of riparian buffers, and controlled flow regimes to mitigate adverse outcomes and enhance the resilience of inland water resources in a warming world.

Keywords: Global warming, lakes, rivers, water quality

INTRODUCTION

Freshwater ecosystems provide drinking water, facilitate food production, and provide the foundation for energy production and biodiversity. Anthropogenic climate change is transforming the hydrology and water quality of lakes and rivers by altering key climatic drivers such as temperature, changes in precipitation patterns, evaporation, snow and glacier melt, and sea level. Intensification of the hydrological cycle (e.g., higher atmospheric humidity and more intense precipitation per degree of warming), earlier snowmelt, and increased terrestrial evaporation are observed with high confidence, along with regionally heterogeneous drying/wetting patterns that shape water quality trajectories through both chronic stresses and extreme events (IPCC WGII). This review integrates mechanistic understanding with recent global syntheses to map how warming alters water temperature regimes, stratification and mixing, oxygen budgets, nutrients, pollutants, and biota, leading to measurable deterioration of water quality indicators and ecosystem services. We highlight the cross-scale interactions between climate forcing, watershed land use, and management (Garrahou et al., 2009; Pershing et. al., 2018; Woolway et al., 2022).

Mechanistic Pathways: From Warming to Water Quality

Thermal Forcing and Lake Stratification

The latest alterations in the global carbon balance and the associated climate tendencies in the thermal and ice dynamics of inland water bodies raise new essential inquiries regarding energy and substance transfer within aquatic systems. Rising air temperatures warm lake surfaces, increase stability, and lengthen stratified periods. Stronger and longer stratification suppresses vertical mixing, reduces oxygen replenishment of bottom waters, and reinforces nutrient and redox stratification. Phenological shifts in onset and breakdown of stratification alter habitat availability and the timing of biogeochemical processes, with cascading effects on primary production and food webs (e.g., trophic mismatches) (Woolway et. al., 2022). Observations and modeling demonstrate earlier stratification onset, prolonged duration, and tendencies toward more frequent and intense lake heatwaves, with clear anthropogenic attribution. Subsurface (metalimnetic/hypolimnetic) heatwaves are also being documented, extending thermal stress below the surface (Woolway et. al., 2021; Kirillin, Shatwell, 2016).

River Thermal Regimes and Hydroclimatic Extremes

Hydroclimatological dynamics shape river discharge (i.e., streamflow). While numerous interacting factors affect the condition of river ecosystems—such as light availability, thermal regime, nutrient supply, spatial connectivity, biodiversity, and human management—discharge remains a fundamental driver in defining the structural framework of river habitats (Laize et al., 2014). In rivers, warming elevates water temperatures, while droughts and heatwaves reduce flows and dilution capacity; floods increase non-point source loads and resuspension of sediments. A synthesis of global case studies shows that river water quality often worsens during droughts and heatwaves due to higher concentrations of nutrients, organic matter (increased BOD/COD), salinity, and pathogens; floods degrade quality via sediment and pollutant pulses. Multidecadal trends in many basins reflect the combined effects of climate change and intensifying extremes (Vliet et.al., 2023)

Oxygen Dynamics and Biogeochemical Feedbacks

Warmer water bodies bind less dissolved oxygen (DO), while increased microbial activity, respiration, mineralization, and sediment oxygen demand further reduce DO. In stratified lakes, bottomwater (hypolimnetic) DO declines are common. In many systems, browning (higher dissolved organic carbon (DOC) increases light attenuation and hypolimnetic respiration, increasing oxygen loss, compressing coldwater habitats, and altering ecosystem metabolism (Jane et. al., 2024).

Nutrients, Internal Loading, and Redox Chemistry

When water oxygen levels decrease or disappear completely, sediments release phosphorus through reductive dissolution of iron oxides, increasing ammonium accumulation; denitrification and anammox alter nitrogen balances. Therefore, stronger and longer stratification with hypolimnetic anoxia increases internal phosphorus load, leading to the risk of eutrophication and harmful algal blooms (HABs) during mixing events and subsequent growing seasons, even when external inputs are reduced (NSTC, 2003; Carpenter, 2005).

Contaminant Mobilization and Salinity Intrusion

Hydroclimatic extremes regulate pollutant pathways: drought concentrates salts and contaminants; floods transport pesticides, pathogens, pharmaceuticals, and microplastics from catchments; sea-level rise promotes salinity intrusion into tidally influenced rivers, threatening drinking-water intakes. The thawing of permafrost and watershed browning mobilize metals and organic carbon, altering acidity and ionic composition in Arctic and mountainous systems (Byl et, al., 2025).

Lakes: Warming, Deoxygenation, and Eutrophication

Lake Heatwaves and Attributed Change

Lake heatwaves—extended intervals of anomalously warm surface water—are becoming more frequent, longer, and more intense. Recorded ecological impacts include mass fish mortalities, shifts in plankton phenology and metabolism, and altered food-web structure. Detection–attribution studies link severe lake heatwaves to anthropogenic warming. Subsurface heatwaves in the metalimnion and hypolimnion are increasingly reported, extending thermal stress into deeper aquatic zones (Woolway et al., 2025).

Widespread Deoxygenation and Habitat Squeeze

Sustained monitoring reveals broad DO decrease in many temperate lakes, driven by warming and stratification effects. Simultaneously, increased terrestrial inputs (browning) intensify hypolimnetic oxygen demand. The net effect is habitat squeeze for cold-water taxa such as salmonids and coregonids as cool, oxygenated waters contract. In many lakes, browning-induced oxygen loss outpaces any surface-cooling benefits for habitat, raising biodiversity risks (Jane et. al., 2024).

Harmful Algal Blooms (HABs) and Toxin Risks

Climate change interacts with nutrient enrichment to increase HAB frequency, duration, and toxicity. Modeling for large reservoirs projects substantial increases in cyanobacterial biomass under plausible warming and stratification scenarios—even with constant nutrient inputs—highlighting the synergism of warming and eutrophication. Treatment plants face challenges related to toxins, taste and odor, and disinfection by-products (Chapra et al., 2017). Climate change and nutrient dynamics influence each other both directly and indirectly. Rising temperatures clearly alter the habitats suitable for harmful algal blooms (HABs). Additionally, climate shifts can drive the expansion of harmful algal species by modifying precipitation patterns—leading in some regions to more frequent droughts, and in others to increased intensity or frequency of storms. Such episodic storm events and broader climate variability impact freshwater flow timing, water residence periods, the scale and timing of nutrient inputs, and the subsequent biological responses (Heisler et al., 2008).

Rivers: Flow Regimes, Extremes, and Quality

Droughts and Heatwaves

During droughts and heat waves, low flows increase residence times, temperatures, and concentrations of nutrients, salts, and pathogens. As dilution decreases, point source contributions increase. Biological oxygen demand increases while DO decreases, stressing the biota and creating treatment challenges for utilities. Observational syntheses indicate that water quality deteriorates under such extremes in the majority of cases (Vilet et al., 2023).

Salinity Intrusion and Heat Stress in Regulated Rivers

In tidal rivers and deltas, sea level rise and drought are advancing salt fronts, threatening water intakes and altering ionic composition. Active reservoir releases and temporary barriers are increasingly being used to control salinity intrusion, demonstrating the interactions of climate risk across water supply and estuary management (Byl et al., 2025).

Water Quality Constituents and Processes

Temperature and Dissolved Oxygen

Direct thermal effects reduce oxygen solubility. Indirect effects (higher respiration, nitrification and denitrification rates, and sediment oxygen demand) further deplete DO. Under low oxygen levels or anoxia, reduced compounds (NH_4^+ , Fe^{2+} , Mn^{2+} , H_2S) accumulate, and emissions of methane (CH_4) and nitrous oxide (N_2O) may increase. (Naqvi et. al., 2010).

Nutrients (Nitrogen and Phosphorus)

Rising temperatures stimulate cyanobacterial blooms and nitrogen-fixing capacity in some species; redox-driven sediment processes increase phosphorus release under oxygen-depleted conditions, while storm events introduce significant external nutrient inputs. Internal nutrient recycling

maintains eutrophic conditions even after external inputs have diminished, highlighting the need for long-term, multifaceted restoration approaches (Nürnberg 2024).

Contaminants and Pathogens

Extreme events mobilize legacy metals, pesticides, and emerging contaminants (pharmaceuticals, PFAS, microplastics), while warm, nutrient-rich waters favor pathogenic bacteria such as *Vibrio* and *E. coli*. Permafrost thaw enhances delivery of DOC and metals to high-latitude rivers and lakes, modifying acidity and redox state with visible ecosystem consequences. The distribution of pathogens and the incidence of waterborne disease outbreaks are closely linked to environmental and climatic conditions. Global climate change will affect the hydrological cycle in many different ways that will influence waterborne pathogen survival, infectivity and distribution (Nicholas, 2014).

Ecological and Health Consequences

Thermal habitat loss and hypoxia reduce niche availability for coldwater and stenothermic species, restructure plankton communities, and increase fish mortality risks during heatwaves and turnover events. Browning and deoxygenation compress vertical habitat, leading to mismatches in predator-prey dynamics (Jane et al., 2024).

HAB toxins (microcystins, anatoxins, cylindrical spermopsin) pose a threat to drinking water safety and recreation; storm-related increases in microbial indicators and pathogens complicate treatment. Warmer waters extend seasonal ranges for some pathogens, requiring more intensive monitoring and risk communication (Elidrissi et al., 2024).

CONCLUSION

Global warming is degrading the water quality of lakes and rivers through thermal, hydrological, biogeochemical, and microbiological pathways. Lakes are experiencing increasingly severe and prolonged stratification, heat waves, and bottom-water anoxic conditions, which increase nutrient loading and the risk of HABs, threatening the health of organisms. Rivers are experiencing quality degradation reflecting changes in pollutant dilution, mobilization, and transformation during droughts, heat waves, and floods. These dynamics threaten ecosystems, human health, and economies; however, targeted adaptation (load reduction, nature-based solutions, and dynamic operations) and robust monitoring and forecasting can significantly reduce these risks. Aligning climate change mitigation with water quality management is crucial for maintaining freshwater security throughout the 21st century.

ABSTRACT

Hazelnut cell suspension culture is an effective method for the production of secondary metabolites and increased productivity in biochemical and biotechnological research. This technology allows for precise control of growth conditions, reduced costs, and mass production of pharmaceutical compounds such as Taxol. The present study was conducted to investigate the effects of methyl jasmonate and H₂O₂ on the levels of secondary metabolites of hazelnut during hazelnut cell suspension culture. Treatments included methyl jasmonate at four concentrations of 100, 150, 250 and 350 mg/L and hydrogen peroxide at concentrations of 0.5 and 1 ml/L along with the control treatment. After the experiment, traits such as fresh weight, dry weight, total phenol and flavonoid content and taxol were determined. The results showed that the use of methyl jasmonate and H₂O₂ had a significant effect on the amount of metabolites studied in hazelnut cell suspension. The use of medium concentration of methyl jasmonate had a better effect on the content of total phenols and flavonoids than different concentrations of H₂O₂. The content of phenol (14.88 mg/g dry weight) and total flavonoids (2.65 mg/g dry weight) was observed in cell suspension samples treated with methyl jasmonate at a concentration of 250 ppm. The results also showed that the highest amount of taxol (308.79 ppm) was observed in samples treated with H₂O₂ at a concentration of 0.5 ml.

Keywords: Taxol, plant growth regulator, cell suspension, *Corylus avellana* L.

INTRODUCTION

Hazelnut (*Corylus avellana* L.) is an economically and medicinally valuable plant, traditionally known as a rich source of proteins (~19%), oils (>60%), vitamins, and minerals (Rezvani et al., 2016). In recent years, growing attention has been directed toward its secondary metabolites, particularly paclitaxel, a diterpenoid alkaloid from the taxane family. Paclitaxel is one of the most important anticancer agents, widely applied in the treatment of breast, ovarian, and lung cancers (Rahpeyma et al., 2015).

Since natural paclitaxel production from yew (*Taxus* spp.) trees is limited and unsustainable, alternative strategies for large-scale and cost-effective production are essential. Plant tissue culture, particularly cell suspension culture, has been recognized as a promising method for producing secondary metabolites, offering advantages such as controlled growth conditions, reproducibility, and scalability (Sobhani Zadeh et al., 2025).

Among the key factors influencing secondary metabolite biosynthesis are culture medium composition, callus age, carbohydrate source, and the use of elicitors. Elicitors such as methyl jasmonate, salicylic acid, chitosan, and hydrogen peroxide can trigger signaling pathways that enhance secondary metabolite accumulation (Zhang et al., 2001; Jiasari et al., 2023). In this study, we investigated the effects of MeJA and H₂O₂ on the growth characteristics and secondary metabolite profiles of hazelnut cell suspension cultures, with emphasis on paclitaxel production.

MATERIALS AND METHODS

Mature hazelnut seeds were collected from the Rudsar Research Station. After surface sterilization with ethanol and sodium hypochlorite, seeds were cultured on MS medium supplemented with 2,4-D, BA, and NAA for callus induction. Friable and whitish calli were transferred to liquid MS medium to establish suspension cultures.

Treatments consisted of four concentrations of MeJA (100, 150, 250, and 350 ppm) and two concentrations of H₂O₂ (0.5 and 1 mM), along with a control. The experiment was arranged in a completely randomized design with five replicates. At the appropriate growth stage, cultures were harvested, and fresh weight (FW), dry weight (DW), TPC, TFC, antioxidant capacity, and paclitaxel content were measured. TPC and TFC were determined using Folin–Ciocalteu and aluminum chloride methods, respectively, whereas paclitaxel was quantified by HPLC (Jakabová et al., 2012; Mita et al., 1997; Pourmorad et al., 2006; Meda et al., 2004; Miliauskas et al., 2004).

RESULTS AND DISCUSSION

Fresh and dry weight

Both MeJA and H₂O₂ treatments significantly influenced biomass accumulation. Increasing concentrations of elicitors led to a decline in FW and DW. The highest biomass values were recorded under 150 ppm MeJA, with 74.46% and 75.01% increases in FW and DW, respectively, compared with the control. These results confirm the dual role of H₂O₂: acting as a signaling molecule at lower concentrations while exerting cytotoxic effects at higher levels (Hu et al., 2016).

Total phenolic and flavonoid contents

MeJA at 250 ppm resulted in the highest increases in TPC and TFC (39.75% and 71.69% higher than the control, respectively). At higher concentrations, both traits declined significantly. Similarly, H₂O₂ enhanced phenolic and flavonoid production by activating enzymes such as phenylalanine ammonia-lyase (PAL) (Barba-Espín et al., 2021). These findings emphasize the importance of optimizing elicitor concentration to maximize metabolite accumulation (Fan et al., 2024).

Total antioxidant capacity

Antioxidant activity increased in response to both elicitors, with the highest level observed under 250 ppm MeJA. This effect is attributed to the activation of enzymes such as chalcone synthase (CHS) and stilbene synthase (STS), leading to enhanced antioxidant compound biosynthesis (Ghanati et al., 2011; Goktep-Atilgan et al., 2023).

Paclitaxel content

HPLC analysis revealed that both elicitors significantly enhanced paclitaxel production. The maximum paclitaxel concentration (308.79 ppm) was obtained with 0.5 mM H₂O₂, representing a 65.95% increase compared with the control. MeJA also promoted paclitaxel accumulation, with the most pronounced effect at 250 ppm. These results corroborate previous studies highlighting the positive effects of oxidative and hormonal elicitors on taxane biosynthesis (Kim et al., 2017; Yan et al., 2020; Liao et al., 2024).

Correlation analysis

Correlation analysis indicated a negative relationship between paclitaxel accumulation and biomass (FW and DW), but a positive correlation with TPC. This suggests a trade-off between primary growth and secondary metabolism. A strong positive correlation between TFC and antioxidant activity further supports the complementary role of flavonoids in plant defense responses to stress and elicitors (Ramachandra and Ravishankar, 2002; Panche et al., 2016).

Figure 1. Growth curve of hazelnut cell suspension cultures

CONCLUSION

The present study demonstrates that both methyl jasmonate and hydrogen peroxide are effective elicitors for stimulating secondary metabolism in hazelnut suspension cultures. Although biomass decreased with higher elicitor concentrations, secondary metabolites, particularly phenolics, flavonoids, antioxidants, and paclitaxel, increased significantly. Optimal results were obtained at 250 ppm MeJA (for phenolics and flavonoids) and 0.5 mM H₂O₂ (for paclitaxel). These findings underscore the significance of optimizing elicitor type and concentration to achieve balanced growth and metabolite production. The observed correlations also highlight the metabolic trade-offs between cell growth and secondary metabolite biosynthesis. Future work should focus on refining elicitation strategies, including timing, combination treatments, and scale-up approaches, to further enhance paclitaxel production in hazelnut cell cultures for potential industrial applications.

ABSTRACT

Pathogenic bacterial microorganisms cause an important threat to human health and can result in infectious diseases. These bacteria can spread through various environments such as food and water. Mercury is a heavy metal that is highly persistent in the environment and has extremely strong toxic effects. Therefore, this research aimed to determine the mercury resistance of eight distinct pathogenic reference strains using the broth microdilution method and to identify the presence of the *merA* gene using the PCR method. Out of the eight pathogenic reference strains, five (62.5%) strains were resistant to mercury. The highest minimum inhibitory concentration (MIC) value, with 16 µg/mL, was observed in *Pseudomonas aeruginosa* ATCC 27853 and *Enterobacter cloacae* NCIMB 13597 strains. Mercury-sensitive bacteria such as *Salmonella* Typhimurium ATCC 13311, *Staphylococcus aureus* ATCC 29213, and *Escherichia coli* ATCC 25922 had a minimum inhibitory concentration (MIC) of 1 µg/mL. All mercury-resistant strains were also positive for the *merA* gene, except for *Enterococcus faecalis* ATCC 51299. Mercury-sensitive strains did not carry the *merA* gene. The findings demonstrate an important correlation between the existence of the *merA* gene and mercury resistance and emphasize the need for detecting heavy metal resistance in pathogenic bacteria for public health.

Keywords: Pathogenic bacteria, mercury resistance, *merA* gene, MIC

INTRODUCTION

Human health is significantly affected by bacteria, especially pathogenic bacteria, which are responsible for millions of deaths each year (Mocan et al., 2017; Fan et al., 2019). These bacteria can be transmitted through food, water, and airborne transmission to the human body via multiple pathways, causing diseases that pose a significant threat to human health. Pathogenic infections cause many diseases, including septicemia, recurrent intestinal inflammation, and soft tissue infections (Mi et al., 2022).

Contamination of both surface and groundwater by heavy metals is a worldwide concern. For humans and other living things, heavy metals can pose acute and long-term health risks. Exposure to heavy metals can result in health problems including depression, cancer, renal problems, headaches, nausea, and skin irritation (Li et al., 2019; Imron et al., 2021). The release of hazardous heavy metal-containing industrial wastewater and the resulting accumulation of these metals in the environment can be extremely dangerous for human, animal, and plant health (Nanda et al., 2019). Mercury (Hg)

is a persistent environmental pollutant with significant toxicity, and elemental gaseous mercury can travel great distances within the soil and plant (Guo et al., 2024).

Mercury is a hazardous non-essential metal that has serious physiological consequences even in small concentrations (Kiyono et al., 2013). Even at very low levels, mercury can be harmful, particularly to the developing fetus and child. Importantly, the toxicokinetic of Hg vary depending on the mode of exposure (inhalation, oral, or cutaneous) and the type of mercury to which one is exposed (Miklavčič et al., 2013). The fundamental mechanism of cellular damage is the interaction of mercury with decreased sulfhydryl groups on significant proteins. These macromolecules are bound by mercury, which disrupts with their usual biological functions and changes the metabolism of cells. Histological studies have confirmed that mercury toxicity can cause atrophy of the central nervous system (Kiyono et al., 2013).

Mercury due to its toxic effect causes the development of various resistance mechanisms in bacteria (Barkay et al., 2003). The *merA* gene, which plays an important role in resistance, encodes the mercuric reductase enzyme (Christakis et al., 2021). Mercury also leads to the spread of antimicrobial resistance because genes encoding the *mer* system often move on mobile genetic elements containing antimicrobial resistance genes (Lloyd et al., 2016). Furthermore, the emergence of resistant strains, which are more difficult to treat and are linked with increased rates of morbidity and mortality, can be prevented by the rapid dissemination of resistance genes by horizontal gene transfer (Hembach et al., 2022).

Salmonella is a zoonotic pathogen that can cause food poisoning, which can result in gastroenteritis, sepsis, enteric fever, and typhoid fever (Tan et al., 2022; Yang et al., 2025). *Escherichia coli*, an *Enterobacteriaceae* family member, is found in both human and animal gut microbiota (Levinson, 2016). Typically, they are released into the environment, and they can contaminate foods, soil, and water (Bhunia, 2008). *Pseudomonas aeruginosa* is a flagellated, Gram-negative bacterium that readily adapts to novel environments. Bacteria are considered an opportunistic pathogen, causing pneumonia in immunocompromised patients (Goncalves-de-Albuquerque et al., 2016). The *Enterobacteriaceae* family includes *Klebsiella pneumoniae*, a Gram-negative rod-shaped bacterium. It is also an opportunistic pathogen that can be found in the nasal and oral cavities, skin, and intestines as well as in hospitals and clinics tools. This pathogen causes a number of common infections, such as bacteremia, pneumonia, wound infections, and urinary tract infections (UTIs) (Li et al., 2014; Li and Ni, 2023). *Enterobacter cloacae* is commonly found in soil, water, and plants. It is a common hospital-acquired disease and can be an opportunistic pathogen, particularly in immunocompromised individuals (Izdebski et al., 2015). *Staphylococcus aureus* can cause many human diseases, such as pneumonia, meningitis, impetigo, mastitis, endocarditis, toxic shock syndrome osteomyelitis, food poisoning, and gastrointestinal tract infections (Bhunia, 2008; Tong et al., 2015; Özdemir, 2022). *Enterococcus faecalis* is a potentially pathogenic bacterium found in the intestine, oral, and reproductive systems of people and animals. It causes various types of infectious illnesses (Xiang et al., 2024).

Mercury is a very toxic and harmful heavy metal that poses a major threat to both human health and the surrounding environment. The objective of this study was to test mercury resistance using the broth microdilution method and to detect the presence of mercury reductase, which is encoded by the *merA* gene, using PCR.

MATERIALS AND METHODS

Bacterial strains

In this study, a total of eight ATCC reference strains were used. Gram-negative bacteria included *Pseudomonas aeruginosa* ATCC 27853, *Escherichia coli* ATCC 25922, *Salmonella* Typhimurium ATCC 13311, *Enterobacter cloacae* NCIMB 13597, *Klebsiella pneumoniae* ATCC 700603, and *Escherichia coli* ATCC 35218. The Gram-positive bacteria were *Staphylococcus aureus* ATCC 29213 and *Enterococcus faecalis* ATCC 51299. DNA was obtained with the cetyl trimethyl ammonium bromide (CTAB) method and was then kept at -20°C.

Determination of the mercury minimum inhibitory concentration

The mercury chloride (HgCl₂) used in this study was supplied by Sinopharm Chemical Reagent Co., Ltd. (Shanghai, China). The broth microdilution method was used to determine the minimum inhibitory concentrations (MICs) of mercury quantitatively on a sterile 96-well microtiter plate (Lp Italiana) (CLSI, 2012; He et al., 2016; Dahanayake et al., 2019). The concentrations tested for mercury (Hg) varied between 64 µg/mL and 0.125 µg/mL. MICs were determined by calculating the lowest concentration, after 18–20 hours of incubation at 37°C, completely inhibited organism development. The optical density at 600 nm wavelength was measured (Thermo Electron Corporation, Finland). Three duplicates of each test were performed. Reference strains tested in this study were accepted as resistant if their MIC values were higher than the MIC result of *Escherichia coli* K-12, which was used as control strain those of the control strain (Dahanayake et al., 2019).

Determination of mercury minimum bactericidal concentration

After the incubation and plate reading, turbidity was observed in the wells. Based on this turbidity, possible minimum bactericidal concentration (MBC) value ranges were determined and 10 µL of the first eight dilutions (64, 32, 16, 8, 4, 2, 1, 0.5 µg/mL) were inoculated onto Mueller Hinton agar (Merck, Germany). The plates were incubated for 24 h at 37°C. After agar plates were examined, MBC was determined to be the lowest mercury concentration at which no bacterial growth developed.

Detection of mercury resistance gene by PCR

PCR was used to test for the presence of the *merA* gene, which encodes mercury reductase, to determine Hg resistance. The primers for the *merA* gene were forward primer, 5'-GAGATCTAAAGCACGCTAAGGC-3', and reverse primer, 5'-GGAATCTTGACTGTGATCGGG-3' (Misra et al., 1984). The predicted size was 1011 bp. PCR was performed in a reaction volume of 50 µL containing 5 µL of 10× PCR buffer (Thermo Scientific), 2 mM MgCl₂ (Thermo Scientific), 0.2 mM dNTP mix (Thermo Scientific), 0.4 µM primer (Oligomer Biotechnology), 1.5 U Taq DNA polymerase (Thermo Scientific), 5 µL DNA template (50 ng/µL), and 30.7 µL PCR-grade water (AppliChem, Germany). The cycling conditions were carried out with the following setup: initial denaturation (94°C for 3 min), 35 cycles of denaturation (94°C for 30 s), annealing (57°C for 30 s), extension (72°C for 1 min), final extension (72°C for 5 min). PCR experiments were performed using a thermal cycler (Bio-Rad T100). Electrophoresis (BioRad) was used to examine amplified PCR products on a 1% agarose gel and UV transilluminator (DNR Minilumi Bioimaging Systems) for visualization. The molecular size of DNA fragments was determined with a 100-bp DNA ladder (Vivantis). *E. coli* ATCC 35218 was a positive control for the *merA* gene.

RESULTS AND DISCUSSION

In this study, mercury (HgCl₂) MIC, MBC values and *merA* gene presence were determined for eight different pathogenic reference strains. According to the *E. coli* K-12 MIC value, five of the eight pathogenic reference strains showed resistance to Hg at different MIC values (4-16 µg/mL). Table 1 shows the strains that are resistant and sensitive to mercury. Out of the eight pathogenic reference strains, five (62.5%) strains were resistant to Hg. These were *E. faecalis* ATCC 51299 MIC value of 4 µg/mL, *K. pneumoniae* ATCC 700603 and *E. coli* ATCC 35218 MIC value of 8 µg/mL, *P. aeruginosa* ATCC 27853 and *E. cloacae* NCIMB 13597 MIC value of 16 µg/mL. The bacterial type strains including *E. coli* ATCC 25922, *S. Typhimurium* ATCC 13311, and *S. aureus* ATCC 29213 had MIC value of 1 µg/mL. Thus, these strains were considered as mercury-sensitive according to *E. coli* K-12 MIC value. The MBC values of the strains were parallel to their MIC values, except for *E. faecalis* ATCC 51299. Figure 1 shows the MBC results. Interestingly, although all mercury-resistant strains carried the (50%) *merA* gene, *E. faecalis* ATCC 51299 did not also harbor the *merA* gene. The presence of the *merA* resistance gene in the pathogenic reference strains was detected and PCR products were visualized using agar gel electrophoresis as shown in Figure 2.

Table 1. Minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) values of mercury and the presence of the *merA* gene for pathogenic reference strains

No	Reference Strains	MIC (µg/mL)	MBC (µg/mL)	<i>merA</i> gene
1	<i>E. coli</i> ATCC 25922	1	1	-
2	<i>S. Typhimurium</i> ATCC 13311	1	1	-
3	<i>P. aeruginosa</i> ATCC 27853	16	16	+
4	<i>S. aureus</i> ATCC 29213	1	1	-
5	<i>E. faecalis</i> ATCC 51299	4	16	-
6	<i>E. cloacae</i> NCIMB 13597	16	16	+
7	<i>K. pneumoniae</i> ATCC 700603	8	8	+
8	<i>E. coli</i> ATCC 35218	8	8	+
Control	<i>E. coli</i> K-12*	2	2	-

*Reference strains were considered resistant if their MIC values surpassed those of the control strain.

Zhou et al. (2019) found that *Pseudomonas aeruginosa* strains isolated from a mercury-contaminated river sediment in China had an MIC value of approximately 10 mg/L against HgCl₂. The high MIC values obtained in this study indicated that environmental *P. aeruginosa* strains can develop significant resistance mechanisms under chronic heavy metal exposure. In a study by Skurnik et al. (2010), MIC values for Hg-resistant *E. coli* isolates were reported as ≥ 64 mM and for susceptible isolates as ≤ 16 mM. Our Hg MIC results in the range of 0.25 to 64 μ g/mL obtained in pathogenic reference strains are parallel to both the studies conducted in environmental *E. coli* strains (de Luca Rebello et al., 2013) and the values reported by Skurnik et al. (2010) in clinical isolates. The MIC value of HgCl₂ against industrially sourced *Enterobacter* sp. AZ-15 isolates was reported as 20 μ g/mL (Amin et al., 2017), which was consistent with our Hg MIC value in this study for pathogenic *Enterobacter cloacae* NCIMB 13597.

Figure 1. MBC plates of mercury-resistant (A-B) strains. A. *K. pneumoniae* ATCC 706003, B. *P. aeruginosa* ATCC 27853. Mercury concentrations for numbers 1, 2, 3, 4, 5, 6, 7, and 8 are 64, 32, 16, 8, 4, 2, 1, and 0.5 μ g/mL, respectively.

Figure 2. Agarose gel electrophoresis of the *merA* gene (1011 bp). Lane M: 100 bp Marker. Lane 1: *E. coli* ATCC 35218 Lanes 2-4: Positive strains for *merA* gene: *P. aeruginosa* ATCC 27853, *E. faecalis* NCIMB 13597, and *K. pneumoniae* ATCC 700603, respectively.

Several studies have found that different bacterial strains have developed resistance to mercury and other heavy metals. In Shanghai, He et al. (2016) discovered that *Vibrio parahaemolyticus* isolates from fresh shrimp from fish markets had Hg MIC values ranging from 6.25 to 50 µg/mL. In contrast, mercury resistance was not detected in *Aeromonas* spp. isolates from Pacific abalone samples collected in Korea (Wickramanayake et al., 2020). Furthermore, Singh et al. (2013) reported that all *Bacillus* isolates examined in their study exhibited high mercury resistance, with MICs ranging from 125 to 180 µg/mL, indicating that Gram-positive bacteria may also possess strong heavy metal tolerance mechanisms. In contrast, the low MIC value reported in our study and the lack of the *merA* gene are not consistent with this finding. In contrast to our results (50%), Skurnik et al. (2010) detected the *merA* gene in all mercury-resistant isolates. Yang et al. (2020) found a low occurrence of the *merA* gene in the isolates of *E. coli* (2.5%) and *Salmonella* (11.4%) from chicken broiler farms and retail meat, indicating genotypic Hg resistance. In Korea, 17 (47%) *Aeromonas* strains from the Manila clam carried the *merA* gene. Cufaoglu et al. (2022) found that the *merA* gene was more common (50%) in the isolates of *E. coli* from sheep, cattle, and chickens.

CONCLUSIONS

This study revealed the resistance of different pathogen reference strains to the heavy metal mercury with their MIC and MBC values. Most of Hg-resistant strains harbored the *merA* gene associated with mercury resistance. A relationship between mercury resistance and the presence of the *merA* gene was observed. As a result, determining the occurrence of mercury-resistant bacteria may be crucial due to their harmfulness to human health.

ABSTRACT

Staphylococcus aureus, a Gram-positive and coagulase-positive bacterium, serves as both a commensal and opportunistic pathogen in mammals. It can potentially cause a wide range of severe and fatal diseases. Biofilm production is an essential virulence factor in pathogenic bacteria including *S. aureus*. Biofilms have a major role in their pathogenesis and persistence. *S. aureus* biofilm is mediated by the *icaABCD* gene cluster, which regulates intercellular adhesion and exopolysaccharide matrix production, facilitating biofilm development and long-term bacterial survival. A total of 11 *S. aureus* isolates from chicken meat were tested for biofilm formation using microtiter plates and the presence of *icaABCD* genes using PCR. All isolates were biofilm producers. Three isolates (27.2%) were classified as weak, four isolates (36.6%) as moderate, and four isolates (36.6%) as strong biofilm producers. All the isolates were positive for *icaAD* genes. In addition, 10 isolates (90.6%) were positive for *icaB* whereas eight isolates (54.5%) were positive for *icaC*. In this study, *S. aureus* isolates from chicken meat demonstrated the biofilm formation ability by the quantitative microtiter plate method and the presence of *icaABCD* biofilm forming genes by the PCR method, emphasizing the risk of food contamination and public health concerns.

Keywords: Biofilm, *icaABCD*, chicken meat, *Staphylococcus aureus*

INTRODUCTION

Staphylococcus aureus, one of the Gram-positive bacteria, is the most prevalent pathogen in the *Staphylococcus* genus (Götz et al., 2006; Bhunia, 2008). In the human body, *S. aureus* lives as commensal bacteria (Wang et al., 2023). *S. aureus* grow at temperatures between 15°C and 45°C, with NaCl concentrations up to 15% (Wu et al., 2018). One of the most significant organisms that causes nosocomial and community-acquired illnesses (Mirzaee et al., 2015). *S. aureus* can cause many diseases, such as soft tissue infections, endocarditis, and pneumonia (Wang et al., 2023). *S. aureus* can secrete a variety of virulence factors, including enzymes, exotoxins, and surface protein adhesins, which help to initiate adhesion, inhibition or evasion of the immune system of host (Mirzaee et al., 2015). *S. aureus* biofilm production promotes the establishment of antimicrobial-resistant bacteria, such as methicillin-resistant and vancomycin-resistant *S. aureus* (Ahn et al., 2018). Furthermore, its ability to produce biofilms on both biotic and abiotic surfaces increases its pathogenicity and persistence. (Zhao et al., 2017).

Biofilms are organized communities of microorganisms that grow and adhere to surfaces that are embedded in extracellular polymeric substances, which are made up of polysaccharides, lipids,

proteins, and nucleic acids (Reungvisesh et al., 2023). Biofilm production in the food industry increases bacterial resistance to environmental difficulties such as dehydration, washing, and sanitation because the extracellular polymeric substance that covers microbial cells serve as a barrier to movement (Rather et al., 2021). Biofilm consists of four stages, attachment, colonization, biofilm maturation and dispersal respectively (Lister and Horswill, 2014). Numerous factors influence bacterial attachment and biofilm formation, including the type of surface material, ambient conditions (such as pH and temperature), the kind of medium, the species of bacteria in the biofilm, exposure duration, and the kind of cleaning and disinfection chemical used (Lake et al., 2024). Multiple factors, including the growth medium, surface characteristics, and other environmental conditions, influence the biofilm formation ability of microorganisms such as *S. aureus* (Jeronimo et al., 2012; Zhao et al., 2017).

Another important component needed for biofilm production and maturation is the polysaccharide intercellular adhesin (PIA) (Mirzaee et al., 2015). The *ica* operon, which includes the *icaABCD* genes and the regulatory gene *icaR*, encodes both PIA synthesis and transcriptional control (Levinson, 2016; Özdemir et al., 2021). Biofilm development requires the products of the locus *icaABCD* genes, and *icaA* and *icaD* gene products are essential for this process (Király et al., 2024). When the *ica* locus in *S. aureus* is deleted, the production of PIA is stopped, and the ability of the bacteria to generate biofilm is also lost (Götz et al., 2006). *Staphylococcus* biofilm formation has been most extensively studied with the *icaABCD* gene cluster. The *icaABCD* genes indicate that the bacteria can produce biofilms (Pizauro et al., 2021). Since the identification and characterization of genes that regulate biofilm formation, there has been an increasing interest in the role of bacterial biofilms in clinical illnesses (Mirzaee et al., 2015).

Contamination with bacteria has been discovered throughout the manufacturing chain, from farm to fork (Klaharn et al., 2023). It has been determined to happen predominantly during the slaughter process, with plucking, cutting, and freezing being the most crucial procedures (Klaharn et al., 2023; Beshiru et al., 2023). *S. aureus* can contaminate chicken meat during processing, with multidrug-resistant and enterotoxigenic strains frequently isolated from retail poultry products (Osman et al., 2016).

During processing, handling, and storage, *S. aureus* can contaminate chicken meat through contact with unhygienic surfaces, equipment, or human skin. Biofilms pose a major problem in the food industry because of their capacity to develop biofilms on encounter food surfaces (Reungvisesh et al., 2023). Therefore, the aim of this study was to determine biofilm formation in *S. aureus* isolates from chicken meat and the presence of biofilm-associated *icaABCD* genes.

MATERIALS AND METHODS

Bacterial isolates

In this study, 11 *S. aureus* isolates from chicken meat, identified and confirmed by both biochemical testing and the species-specific Sa442 DNA fragment, were used. All isolates were revived from stock culture. Isolates were plated on tryptic soy agar (Merck, Germany) and incubated at 37°C for 24 h. For future research, these cultures were preserved tryptic soy broth with glycerol (20%) and kept at -20°C.

Detection of biofilm formation

The isolates were grown in tryptic soy broth (TSB) (Merck) at 37°C for 24 h. A plate containing 200 µL of cell suspension per well was incubated for 24 hours. After incubation, the wells of the microtiter plate were washed with sterile phosphate buffered saline (PBS). The remaining adhered bacteria were fixed with 200 µL of 99% methanol (Merck) for 15 min. Next, 200 µL of 0.1% crystal violet was applied to each well to stain the biofilm. The stained biofilm was dissolved using a solution of 33% glacial acetic acid (Merck) in 160 µL. Finally, the biofilm formation activity was measured at 570 nanometers by the microplate reader (Thermo Electron Corporation, Finland). Three duplicates of each experiment were performed. Only sterile TSB was present in negative control wells. Isolates as were categorized as strong, moderate, weak and nonbiofilm producers (Stepanovic et al., 2000; Stepanovic et al., 2007).

Detection of the *icaABCD* genes

The DNA of the isolates was extracted using the cetyl trimethyl ammonium bromide (CTAB) technique (Ausubel et al., 1991). The PCR assays were conducted using the primers listed in Table 1. The PCR mixture (50 µL) included 0.3 mM of forward and reverse primers (Biomers, Germany), 5 µL DNA template, 5 µL 10 X PCR buffer (Thermo Scientific), 200 µM dNTP mix (Thermo Scientific), 4 mM MgCl₂ (Thermo Fisher Scientific), 1.5 U Taq DNA polymerase (Thermo Scientific), and 31.7 µL of PCR-grade water (Applichem, Germany). The cycling process includes initial denaturation (94 °C /5 min), 30 cycles of denaturation (94°C /1 min), annealing (52 °C /30 s), extension (72 °C /1 min 30 s), and final extension (72 °C /10 min). All amplifications of DNA were performed out using a thermal cycler (Bio-Rad T100) The PCR product was seen using a UV transilluminator (DNR Minilumi Bio-imaging Systems, Israel). *S. aureus* ATCC 25923 as positive control was used.

RESULTS AND DISCUSSION

S. aureus is a biofilm-producing bacterium and can sustain contamination in chicken meat processing and on contact surfaces (Igbinosa et al., 2023). In the current study, biofilm formation capacity of 11 *S. aureus* isolates isolated from chicken meat was determined using the microtiter plate method. Figure 1 shows the biofilm-forming ability of *S. aureus* isolates from chicken meat. All *S. aureus* isolates demonstrated biofilm-producing capability; among them, three isolates (27.2%) were classified as weak four isolates (36.3%) as moderate and four isolates (36.3%) as strong biofilm producers. Figure 2 illustrates the classification of biofilm formation among the chicken meat *S. aureus* isolates. Our results are consistent with the study reported by (Bisong and Ateba, 2020), in which 90.9% of *S. aureus* from milk produced biofilm and 94.3% exhibited a strong phenotype. In addition, Dai et al. (2019) showed that all *S. aureus* strains isolated from pasteurized milk formed biofilm and 66.7% of them exhibited strong phenotypes.

The intracellular adhesion (*ica*) locus, which is the main factor promoting adhesive contacts between bacterial cells, encodes the genes required for the manufacture of PIA. The *ica* promotes adhesion between biofilm-producing bacterial cells. It also encodes the genes required for PIA production (Király et al., 2024). In this study all *S. aureus* isolates carried the *icaA* and *icaD* genes, but 10 (90.9%) of them had the *icaB* and six (54.5%) had the *icaC* gene. Representative agarose gel photograph of the PCR products of the *icaA* and *icaD* gene is presented in Figure 3. Table 2 shows the degree of biofilm formation capacity and the presence of *icaABCD* genes involved in biofilm formation of the *S. aureus* isolates. Alibegli et al. (2025) found similarly high rates in clinical isolates. Chen et al. (2020) demonstrated that all *S. aureus* from various foods were positive for the *icaADBC* genes, which is consistent with our findings. On the contrary, some studies have documented lower prevalence of *icaA* and *icaD* genes in cheese (76.5% and 58.8%) and milk (25%) samples (Falaki and Mahdavi, 2017; Suvajdzic et al., 2017). In contrast, 52.3% of *S. aureus* isolates from food contact surfaces had *icaADBC* genes (Avila-Novoa et al., 2018). The results of many studies suggest that gene prevalence may vary in isolates of different origins from different geographical regions (Tahmasebi et al., 2019; Parastan et al., 2020; Deepak et al., 2024)

Isolate	Biofilm formation	Biofilm-forming genes			
		<i>icaA</i>	<i>icaB</i>	<i>icaC</i>	<i>icaD</i>
1	Weak	+	+	-	+
2	Strong	+	+	+	+
3	Weak	+	+	+	+
4	Strong	+	+	-	+
5	Weak	+	+	-	+
6	Strong	+	+	+	+
7	Moderate	+	+	+	+
8	Strong	+	+	+	+
9	Moderate	+	+	-	+
10	Moderate	+	+	+	+
11	Moderate	+	-	+	+

CONCLUSIONS

The present study demonstrated that all *S. aureus* isolates were positive for biofilm production. In addition, these isolates from chicken meat had at least one or more of the *icaABCD* genes. It was determined that there might be a link between biofilm formation and the presence of the *icaABCD* genes. Biofilm formation by pathogenic bacteria such as *S. aureus* in food processing environments is the main risk for persistent food contamination that occurs at any stage from production to consumption. As a consequence, prevention of biofilm is necessary since it poses a significant threat to human health, food safety, food quality, and economic loss.

ABSTRACT

It is clear that in order to achieve higher and better-quality yields per unit area, it is not enough to only focus on plant breeding; effective plant nutrition through adequate watering and proper fertilization (based on the plant's phenological stage and in appropriate amounts) is crucial for obtaining the desired results. Growing healthy, high-yielding, and high-quality crops primarily involves proper soil management. In this context, a plant grown in soil with low organic matter levels (below 2%) and consequently reduced microbial diversity will struggle to cope with disease agents (especially soil-borne ones), have low vegetative and generative organ development, and ultimately may not benefit significantly from the minerals present in the soil or added through fertilizers. In addressing this common issue, commercial products containing microorganisms with functional benefits for soil and plants (such as bacteria, fungi, algae, etc.) which can aid in plant nutrition, plant protection, and plant growth regulation represent a significant alternative to chemical inputs (such as chemical fertilizers, pesticides, and synthetic growth regulators). However, to maximize the benefits of these products, it is essential to determine not only their capabilities under laboratory conditions (such as nitrogen fixation, phosphorus solubilization, siderophore production, auxin production, etc.) but also their abilities to colonize plant roots, proliferate in the rhizosphere, and compete in various plant and soil types under greenhouse or field conditions. Moreover, factors such as the type of plant production area (field, garden, greenhouse), production model (conventional, organic, ecological, etc.), plant type (cereal, vegetable, fruit), irrigation method (surface irrigation, pressurized irrigation), and especially soil characteristics (texture, organic matter, lime, pH, etc.) must be considered when selecting the appropriate product(s).

Keywords: Biofertilizer, Biological agent, Biostimulant

INTRODUCTION

Fertilizer is one of the inputs used to ensure the continuity of food and agricultural products necessary to meet basic needs such as nutrition and shelter, which have increased due to the growing population and steadily rising living standards. Ensuring the productivity and sustainability of agricultural lands is possible by returning the plant nutrients lost from the soil due to various reasons back to the soil (TAGEM 2018).

Fertilizers used to increase agricultural production and product quality are generally classified into two categories in the agricultural sector: chemical fertilizers and organic fertilizers (Akmermer

2022). The nutrient content of organic fertilizers is significantly lower compared to chemical fertilizers and is not in a form that plants can directly benefit from. For this reason, organic fertilizers are used for soil regulator purposes rather than meeting the nutritional needs of plants (Yetgin 2010). Chemical fertilizers, on the other hand, typically contain plant nutrients in a form that can be readily absorbed by plants and in high concentrations, allowing nutrient deficiencies to be addressed quickly and easily, with lower costs and labor (Evni ve Kan 2024).

Chemical fertilizers, generally produced as nitrogenous, phosphorous, and potassium-based, play a significant role in increasing crop productivity. However, the intensive use of chemical fertilizers not only enhances crop yields but also brings certain disadvantages. Chemical fertilizers alter the physical, chemical, and biological properties of the soil. Continuous use of chemical fertilizers leads to a decline in soil quality, including a reduction in soil organic matter (SOM) content. Excessive use of chemical fertilizers hardens the soil, reduces soil fertility, pollutes the air, water, and soil, and significantly decreases the availability of soil minerals, thereby posing environmental hazards. The continuous application of chemical fertilizers changes the soil pH, potentially increasing acidity. This can lead to a reduction in beneficial organisms, hinder plant growth and even contribute to an increase in greenhouse gas emissions due to the decrease in organic matter (Pahalvi vd. 2021).

In 2021, nitrogenous fertilizers accounted for most of the global fertilizer production, with a volume of 118.55 million tons, representing 55.53% of the total 213.46 million tons produced worldwide (FAO 2024). Regarding consumption, as shown in Figure 1, it was reported that by 2022, 109.29 million tons of nitrogenous fertilizers, 44.1 million tons of phosphorous fertilizers, and 34.66 million tons of potassium fertilizers were used worldwide (IFASTAT 2024).

Figure 1. Global consumption amounts of N, P₂O₅, and K₂O fertilizers by year (IFASTAT 2024)

Fertilizer production worldwide is shaped regionally according to consumption volumes and raw material resources. Countries with large populations, such as the USA, China, India, Canada and Russia also have extensive agricultural lands, giving them a significant share in fertilizer usage (Figure 2). These countries are also major fertilizer producers (Kocagöz 2022).

Figure 2. Fertilizer usage percentages in various countries worldwide

One of the most significant issues in the fertilizer sector is the dependence on imports for countries lacking raw materials. The supply of essential inputs, such as natural gas and phosphate rock is largely reliant on external sources. This situation makes fertilizer production companies heavily dependent on imports, which can lead to price fluctuations and increases, as well as challenges in ensuring a continuous supply of high-quality raw materials. Additionally, this dependency, coupled with factors such as raw material-producing countries entering the fertilizer production market, intensifies competition. As a result, the global fertilizer market is dominated by a few countries, creating an oligopolistic market structure (TAGEM 2018).

APPLICATION OF MICROBIAL PRODUCTS IN PLANT PRODUCTION

Given the environmental threats associated with the use of chemical fertilizers and considering the high consumption volumes and associated costs for countries lacking raw materials, there is a clear need for alternative solutions due to the economic disadvantages. One of the primary alternative solutions is microbial products, which are directly related to soil organic matter.

With changing climate and ecosystems, biological approaches aimed at improving plant production continue to gain strong support among engineers and academics focused on sustainability in agriculture. In this context, there is a growing global momentum in exploring a wide variety of rhizobacteria with new properties, such as heavy metal detoxification potential (Ma et al. 2011; Wani and Khan 2010). The rhizosphere, the soil region surrounding plant roots, represents the area of intense

microbial activity in the soil (Cantó et al. 2020). Biological fertilizers, also known as bio-fertilizers, are materials composed of living microorganisms that can colonize the rhizosphere and/or penetrate plant tissues. When applied to the plant surface or soil, they fix free nitrogen, process mineral elements from organic and inorganic sources to increase their availability and uptake by plants, and/or stimulate optimal plant growth through the production of secondary metabolites (Çakmakçı 2005). Both prokaryotes (archaea, bacteria and viruses) and eukaryotes (fungi, oomycetes, nematodes, protozoa, algae and arthropods) colonize the rhizosphere. Among these, bacteria and fungi are the most prevalent in terms of population (Buee et al. 2009).

Soil-dwelling microorganisms that enhance plant growth are bacteria living on or around the root surface. They contribute to plant growth and development directly or indirectly by producing and secreting various regulatory chemicals in the rhizosphere. Beneficial microorganisms can help reduce global reliance on chemical fertilizers in agriculture (Ahemad and Kibret 2014). They increase the availability of nutrients such as phosphorus (P), potassium (K), zinc (Zn), selenium (Se), and iron (Fe) in the soil through biochemical processes like dissolution, chelation, mineralization, oxidation, and reduction reactions. Additionally, microorganisms are known to secrete phytohormones, including auxins, cytokinins, abscisic acid, ethylene, brassinosteroids, jasmonic acid, salicylic acid, strigolactones, and gibberellins, which act as plant growth regulators and stress mitigators (Koskey et al. 2021). Various studies have shown that applying rhizobacteria, which promote plant growth under both normal and stressful conditions such as salinity, drought, acidity, or alkalinity, can improve the health and productivity of different plant species (Ahemad and Kibret 2014).

Indirect effects of microbial products include enhancing plant health by suppressing phytopathogens and other harmful microorganisms through parasitism, creating competitive environments for nutrients in the rhizosphere, and producing antagonistic substances such as siderophores, antibiotics, and antimicrobial metabolites. Additionally, these microorganisms generate lytic enzymes like chitinase, glucanase, and protease (Figure 3). Some bacterial genera have been shown to protect plants from fungal and bacterial pathogens. These bacteria employ various mechanisms to inhibit the development of plant pathogens. These mechanisms include colonizing infection sites, competitively excluding pathogens, engaging in antagonistic activities through the secretion of antibiotics and lytic enzymes, and enhancing plant resistance (Bonaterra et al. 2022).

Benefits of PGPR Inoculation to Plants	PGPR Strain(s)	Tested Plant(s)
Tolerance to drought stress	<i>Pseudomonas fluorescens</i> DR11, <i>Enterobacter hormaechei</i> DR16, <i>Pseudomonas migulae</i> DR35, <i>Bacillus subtilis</i> , <i>Achromobacter piechaudii</i> ARV8, <i>Phyllobacterium brassicacearum</i> , <i>Paenibacillus polymyxa</i> , <i>Rhizobium tropici</i> , <i>Azospirillum brasilense</i>	Foxtail millet (<i>Setaria italica</i> L.), Maize (<i>Zea mays</i> L.), Bean (<i>Phaseolus vulgaris</i> L.), <i>Arabidopsis thaliana</i> , Tomato (<i>Lycopersicon esculentum</i> Mill cv. NEW APPROACHES IN THE USE OF MICROBIAL PRODUCTS

While live microorganisms aim to provide beneficial plant nutrition and health properties, it is important to consider the factors that may limit these benefits. Microorganisms that exhibit positive characteristics under laboratory conditions may not always deliver the desired benefits in natural environments due to various environmental factors. Especially, when dealing with disease agents, it is crucial to thoroughly analyze the relationships between plants and pathogens, as well as the prevalent environmental factors in a specific area, before implementing biological control measures. Instead of relying on a single microorganism, applying a population of microorganisms with cooperative traits is

more beneficial, as it creates a stable rhizosphere that provides more effective control against pathogens. In addition to microbial applications, the use of other plant products, such as extracts, biofertilizers and biopesticides, which are natural enemies of pests and/or disease-causing pathogens, also contributes to the success of biological control (Pandit et al. 2022).

In soil, only about 5% of the necessary nutrients are available compared to those in laboratory conditions. Additionally, there is ongoing competition for essential nutrients like nitrogen and carbon, meaning only microorganisms with strong competitive abilities can survive (Shah et al. 2021). Climate change is contributing to a steady increase in soil temperatures (Zhang et al. 2019). This rise impacts microorganisms closely associated with plants, as their optimal growth, diversity, and physiological functions depend on specific temperature ranges (Wu et al. 2010). Deviations from these optimal temperatures can lead to varied outcomes in microorganism-plant interactions. Soil warming notably increases microbial respiration and mortality rates (Wu et al. 2010; Schindlbacher et al. 2011). Moreover, excessive water evaporation and the accumulation of chloride salts, such as sodium chloride (NaCl) and magnesium chloride (MgCl₂), raise soil salinity. This increase in salt concentration adversely affects agricultural microbial biomass, seed germination, and plant development by disrupting osmotic potential and ion exchanges (Sindhu et al. 2022).

Host plant and microorganism interactions often determine host specificity, which can lead to a decrease in microbial benefit rates in many crop plant species. In soils with microbial diversity, the lack of specificity in plant species can lead to high competition among microorganism populations (Figueiredo et al. 2011). Additionally, any changes in biochemical compounds produced by plant roots or signaling molecules produced by microorganisms can disrupt potential symbiotic relationships (Chagas et al. 2018). Another important factor is soil pH. The availability of nutrients in the soil solution, for both plants and microorganisms, is greatly influenced by soil pH. The pH is a measure of the hydrogen ion concentration in the colloidal soil solution and affects most chemical reactions in the soil. Acidic soils are dominated by *Acidobacteria*, while alkaline soils are dominated by *Actinobacteria*, causing shifts in microbial populations with changes in soil pH. This can lead to the failure of the desired population to perform its intended function in microbial product use (Shah et al. 2021). Many rhizobacteria exhibit optimal population and efficacy at a pH level of 6.0 (Roe et al. 1998).

The commercialization and application of biological fertilizers involving live microorganisms begins with a technical procedure to isolate ectophytic or endophytic microorganisms from the rhizosphere and plant tissues, especially the roots. This process starts with bioresearch, where plant or soil samples are collected from diverse environments and subjected to microbial isolation in the laboratory. Once rhizobacteria are isolated, they undergo in vitro screening to evaluate their potential for promoting plant growth or serving as biocontrol agents against phytopathogens. Promising strains demonstrating effective plant growth promotion or biocontrol properties are then tested under controlled environmental conditions to assess their impact on plant development. Effective strains are selected based on these tests and further evaluated under field conditions to determine their ability to enhance crop growth. After successful repeated trials, companies typically proceed to commercialize these biological strains as biological fertilizers and/or biocontrol products, following formulation of the final product (Nakkeeran et al. 2005).

An unconventional approach in the field of microbial products that has emerged due to advances in genetics involves enhancing microorganism species and their efficacy, as well as developing new variants. This approach involves intentionally modifying the genetic material of microorganisms, specifically DNA to improve the beneficial traits of microbial strains. Scientists can alter bacterial DNA using techniques such as CRISPR-Cas9, which allows for specific modifications. This genetic manipulation can help bacteria produce chemicals that assist in their proliferation, growth, stress resistance or more efficient nutrient utilization (Bernela et al. 2021; Hasan et al. 2024).

In recent years, leading global agricultural firms have increasingly focused their investments on bio-based product research. Figure 4 lists the revenues and profits of some international companies in the plant protection sector for the second quarter of 2024. Additionally, Figure 5 shows the targeted revenues from bio-based products and the budgets allocated for research and development (R&D) by these same firms for the year 2024. Comparing the data in both figures reveals that firms leading the world in pesticide production are allocating a significant portion of their current revenues to R&D projects aimed at generating revenues from bio-based products over the next decade.

CONCLUSIONS

In today's rapidly evolving climate conditions and the anticipated impacts in the coming years, factors such as rising temperatures and drought, excessive use of chemical fertilizers, salinity from intense evaporation, global warming and reduced water resources due to unregulated water consumption are critical issues affecting agricultural production. Additionally, changing ecosystems due to climate change, the evolution of harmful pathogens and pests and the resulting resistance changes in nature due to pest control measures are pressing and unresolved problems in agriculture. To address these widespread issues and enhance the sustainability of agricultural production, microbial products containing bacteria, fungi, algae and other microorganisms offer a promising alternative. These products provide functional benefits for soil and plants, including plant nutrition, plant protection, and growth regulation, as alternatives to chemical fertilizers and plant protection products.

Some technical details regarding the use of these products emerge as factors determining their effectiveness. Research and advancements in the field aimed at eliminating environmental factors that limit the usefulness of microorganisms are promising. Similar to breeding efforts for plants to achieve higher yields, resistance to diseases and pests and meeting market quality criteria such as color, shape, brightness and taste, the production of live microbial fertilizers and microbial breeding through new technologies that minimize the impact of environmental conditions on microorganisms have opened up new possibilities in the field. It is encouraging to see international pesticide-producing firms

investing in scientific research in this area. Additionally, the progress made by some plant nutrition and protection companies in Turkey, which are exploring bio-based product research and commercial applications represents a positive development in agricultural practices.

ABSTRACT

Carcinus aestuarii Nardo, 1847 is a portunid crab species native to the Mediterranean Sea. It is commonly found in lagoon systems and is considered a potential bioindicator due to its biological responses to environmental pressures. This study analysed *C. aestuarii* individuals living in different benthic habitats (sand, mud, rock and macroalgae) in Çardak Lagoon, based on morphological and behavioural indicators (e.g. shell change, chela loss and habitat selection). A total of 632 individuals were collected from eight stations during fieldwork conducted between May 2024 and April 2025, and the condition of their shells and the presence of regeneration were recorded for each individual. The findings showed that 67% of individuals in the moulting phase were found in muddy and algal habitats, while the claw loss rate in sandy and rocky habitats increased to 45%. The highest number of individuals (n = 230) was recorded at BS6 station, which has fine sediment with a high organic matter content. The highest shell change rate (21%) was observed at BS1 station, which is muddy and low-energy. The direct effect of habitat structure on crab life strategies (molting, defence and reproduction) was statistically significant ($p < 0.05$). These results imply that the habitat preferences and morphological condition of *C. aestuarii* can serve as biological indicators for evaluating the health of the lagoon. In particular, monitoring molting behaviour provides valuable information for the early detection of habitat pressure in ecological management.

Keywords: *Carcinus aestuarii*, lagoon ecosystems, habitat health, bioindicator, molting, Çardak Lagoon

INTRODUCTION

Coastal lagoons are dynamic transition zones between land and sea that play a crucial role in maintaining biodiversity, supporting fisheries, and providing essential ecosystem services. Due to their semi-enclosed nature, lagoons are highly sensitive to anthropogenic pressures such as pollution, eutrophication, and habitat degradation. Therefore, effective monitoring tools are required to assess their ecological health.

One of the most promising approaches in recent years has been the use of bioindicator species, which reflect environmental changes through their physiological, morphological, or behavioral responses. Among benthic crustaceans, the Mediterranean green crab *Carcinus aestuarii* Nardo, 1847 is a widely distributed portunid species inhabiting lagoons, estuaries, and shallow coastal habitats. Its tolerance to variable salinity and temperature regimes, combined with visible biological responses such as molting frequency, chela loss, and regeneration, make it a strong candidate for bioindicator studies.

Previous research in Mediterranean and Adriatic lagoons has demonstrated that *C. aestuarii* exhibits habitat-dependent variations in abundance, reproduction, and molting cycles (Kevrekidis, 2004; Glamuzina et al., 2017). However, studies directly linking its morphological and behavioral traits to habitat quality remain limited. Assessing these traits in different benthic environments (muddy, sandy, rocky, and algal substrates) provides valuable insights into habitat suitability and ecosystem resilience.

Building on this perspective, the present study aims to evaluate the potential of *C. aestuarii* as a bioindicator of habitat health in Çardak Lagoon (Turkish Straits System). Specifically, it investigates the relationships between habitat structure and key biological parameters—molting stage, chela loss, and regeneration—in order to establish reliable biological indicators that complement traditional physicochemical monitoring. Unlike previous studies that mainly focused on the population structure, reproduction, or feeding ecology of *C. aestuarii*, this study uniquely links its morphological and behavioral responses directly to habitat quality, thereby providing a novel bioindicator-based approach for assessing lagoon ecosystem health.

MATERIAL AND METHOD

This study was carried out in Çardak Lagoon, a semi-enclosed coastal ecosystem located in the Turkish Straits System. The lagoon hosts a variety of benthic habitats, including muddy, sandy, rocky, and algal-dominated areas, each representing distinct environmental conditions. To reflect this heterogeneity, eight sampling stations (BS1–BS7) were selected across the lagoon. BS1 and BS6 were dominated by fine-grained muddy substrates with high organic matter accumulation, BS2 and BS5 represented sandy and rocky areas, BS3 and BS4 consisted of mud with partial algal coverage, while BS7 was situated at the intersection of rocky and muddy grounds, acting as a transitional zone.

Field sampling was conducted during May 2024 and April 2025. Individuals of *Carcinus aestuarii* were collected manually by hand nets and with baited traps during low tide conditions to ensure adequate representation across habitat types. In total, 632 crabs were recorded, with their distribution varying considerably among the stations.

For each captured individual, several biological parameters were examined. The molting stage (intermolt, premolt, and postmolt) was determined by assessing the condition of the exoskeleton, while chela loss and evidence of regeneration were recorded as indicators of physical stress. Sex determination was performed based on abdominal morphology, and the carapace width of each specimen was measured to the nearest 0.1 mm using a digital caliper.

In addition to biological data, physicochemical parameters of the water column were measured in situ at each station using a YSI 6600 multiparameter probe. These included temperature (°C), salinity (‰), dissolved oxygen (mg L⁻¹), and pH. Sediment type and habitat structure were documented visually and verified through sediment grab samples to ensure accurate habitat classification.

The collected data were analyzed both descriptively and statistically. The distribution of individuals among different habitats and stations was compared using the Chi-square test in order to detect significant differences ($p < 0.05$). Frequencies of molting, chela loss, and regeneration were calculated as percentages relative to habitat type. Environmental variables were expressed as mean values with standard deviations, while spatial differences in crab abundance were illustrated with comparative figures and maps. This integrative methodological approach enabled the evaluation of both biological and environmental indicators in assessing habitat health within the lagoon.

RESULT AND DISCUSSION

A total of 632 *Carcinus aestuarii* individuals were collected from eight sampling stations in Çardak Lagoon between May 2024 and April 2025. Their distribution across stations showed marked differences. The highest abundance was recorded at BS6 (230 individuals), followed by BS4 (176 individuals). Moderate counts were observed at BS5 (96 individuals) and BS7 (58 individuals), while BS1, BS2, and BS3 yielded the lowest values with 28, 30, and 15 individuals respectively (Figure 1).

Figure 1. Spatial distribution of *Carcinus aestuarii* individuals across sampling stations (BS1–BS7) in Çardak Lagoon

Seasonal variation was evident in the abundance of *C. aestuarii*. The maximum number of individuals was observed in May (124), followed by July (83) and June (75). Intermediate values were recorded in October (68), August (55), and November (49), while the lowest abundances occurred in February (8) and January (27) (Figure 2).

Figure 2. Monthly variation in the abundance of *Carcinus aestuarii* individuals recorded in Çardak Lagoon

Figure 3. Monthly variation in molting frequency of *Carcinus aestuarii* in Çardak Lagoon

Molting frequency fluctuated throughout the year. The highest number of molting individuals was observed in November (17), followed by August (15), December (13), and April (12). Moderate levels were recorded in March, June, and July, whereas low molting frequencies were noted in January, February, May, and September. No molting individuals were detected in October (Figure 3).

Figure 4. Station-based variation in molting ratio of *Carcinus aestuarii* in Çardak Lagoon

Spatial differences in molting ratios among stations were also evident. The highest molting proportion was observed at BS1 (21%), followed by BS5 (19.5%) and BS4 (16%). Moderate levels were detected at BS6 and BS7 (12% each), while BS2 showed a low proportion (6%), and no molting was recorded at BS3 (0%) (Figure 4).

Chela loss and regeneration varied among habitat types. In sandy and rocky habitats, up to 45% of individuals exhibited chela loss, whereas regeneration was more frequently recorded in muddy and algal stations. Statistical analysis confirmed that these differences were significant (Chi-square test, $p < 0.05$). Finally, the spatial distribution of benthic habitat types in Çardak Lagoon was mapped. Sandy and algal substrates were concentrated in the western lagoon, while muddy and rocky substrates were dominant in the eastern part (Figure 5). This heterogeneity in substrate composition provided a basis for analyzing the relationship between habitat structure and the biological responses of *C. aestuarii*.

Figure 5. Spatial distribution of benthic habitat types (sand, mud, rocky, and algal substrates) in Çardak Lagoon

The moulting phase is a period during which soft-shelled individuals are more vulnerable to predation. Consequently, they have been observed seeking out more sheltered microhabitats. The rate of chela loss in open areas suggests greater environmental pressure and competition. These observations support the idea that the habitat selection and morphological posture of *C. aestuarii* may act as biological indicators of lagoon health. Our study evaluated the distribution and morphological responses of *C. aestuarii* across different habitats (mud, sand, rock and algae) within the Çardak lagoon. The results were then compared with those of other habitat-based studies. The results showed that the species was particularly concentrated in muddy and algal areas, and that it tended towards more sheltered habitats during the moulting phase. These results are consistent with those reported in studies conducted in the Venice Lagoon and other Mediterranean lagoons, which indicated that structurally complex habitats, such as seagrass beds, rocky areas and mussel beds, are preferred for

moulting and sheltering behaviour (Mancinelli et al., 2013; Glamuzina et al., 2017). Therefore, *C. aestuarii*'s tendency to select sheltered areas during vulnerable periods is consistent with our study and previous research. On the other hand, this study highlights lagoon-specific conditions that may influence the distribution and life history characteristics of crabs by revealing differences between stations. For example, the particularly high moulting rate at BS1 suggests that environmental factors such as oxygen regime and nutrient cycling in low-energy muddy areas may play a significant role in triggering moulting. Conversely, the absence of moulting individuals at BS3 indicates that habitat quality in this area is not optimal. The moulting cycle of *Carcinus aestuarii*, a key species in many lagoon ecosystems, is affected by various environmental factors, including temperature, salinity and food availability. Seasonal changes play a significant role in determining the moulting timing of this species of crab, particularly in Mediterranean lagoons, where it is commonly found. Studies have shown that *C. aestuarii* generally exhibits higher activity and abundance during the warmer months (May to October), which is associated with higher water temperatures that increase metabolic rates and feeding in crustaceans. A study conducted in Monolimni Lagoon reported that the *C. aestuarii* population peaked in May and June, indicating a direct relationship between increased temperature and biological activity. This could affect moulting frequency and success (Kevrekidis, 2004). Similarly, Acar and Ateş emphasised that environmental conditions such as temperature and salinity directly affect the growth and reproductive characteristics of *C. aestuarii* (Acar & Ateş, 2020), implying that moulting times differ in different lagoons. Furthermore, salinity levels are also crucial. As a species inhabiting both rivers and lagoons, *C. aestuarii* can adapt significantly to fluctuating salinity levels, which can also influence moulting behaviour. Salinity fluctuations can cause stress responses that may delay the moulting process, indicating that changing lagoon conditions in heterogeneous environments can lead to different moulting programmes (Acar & Ateş, 2021; Rivera-Ingraham et al., 2015). Additionally, high summer temperatures not only accelerate metabolic processes but also require the organism to effectively manage its osmoregulation. This is particularly important during moulting, as any environmental stress can jeopardise this sensitive phase (Glamuzina et al., 2017). The economic importance of soft-shell crabs, particularly in the fishing industry, reflects their annual moulting cycles. The seafood industry in the Venetian Lagoon highlights the economic significance of harvesting crabs during their moulting period, when they are most vulnerable yet most valuable (Cilenti et al., 2024). The economic perspective under discussion here emphasises the necessity of understanding and accurately predicting moulting cycles in order to optimise sustainable harvesting practices. Research studies have also examined the biochemical and physiological responses during moulting under changing environmental conditions. Research has demonstrated that crabs undergo fluctuations in metabolic markers that are associated with the moulting cycle. This suggests that environmental stresses have the capacity to alter moulting times (Cogo et al., 2018; Matozzo et al., 2011). For instance, the maintenance of suitable temperature and salinity ranges is imperative to optimise the moulting period, a process that exerts a substantial influence on population dynamics within lagoon ecosystems. In concluding this study, it is evident that the moulting time of *Carcinus aestuarii* in lagoon ecosystems is a multifaceted interaction of seasonal climatic effects, environmental salinity and temperature changes, which significantly affects its life cycle and economic viability. In order to make accurate predictions about these cycles, further integrated studies are required to examine the physiological adaptations and responses of *C. aestuarii* to its dynamic habitat.

CONCLUSIONS

This study demonstrated that *Carcinus aestuarii* can serve as a valuable bioindicator species for assessing habitat health in lagoon ecosystems. The results revealed clear spatial and temporal

variations in the abundance and biological responses of the species within Çardak Lagoon. Individual density was highest in muddy and organic matter-rich habitats, particularly at stations BS6 and BS4, while sandy and rocky substrates supported fewer individuals. Seasonal patterns showed that population abundance increased notably during late spring and summer, corresponding with favorable environmental conditions and potential reproductive activity. Molting frequency and chela loss provided further insights into habitat quality. Molting individuals were predominantly observed in sheltered habitats such as muddy and algal areas, whereas chela loss was more common in exposed sandy and rocky habitats, indicating higher physical stress and predation risk. These findings confirm that the morphological and behavioral traits of *C. aestuarii* reflect habitat characteristics and environmental pressures.

In view of these findings it is recommended that *Carcinus aestuarii* be integrated into long-term lagoon biomonitoring programs as a practical and cost-effective bioindicator species. Standardizing biological responses such as molting frequency, chela loss, and regeneration alongside physicochemical parameters would provide a more holistic understanding of habitat health. Conservation strategies should particularly emphasize the protection of muddy and algal habitats, which support critical life stages of the species and serve as ecological hotspots within lagoon systems. Furthermore, future research should adopt multivariate analytical approaches to strengthen the link between environmental drivers and biological responses, thereby improving predictive capacity in ecosystem assessments. Given the ecological and economic relevance of *C. aestuarii*, especially in the context of soft-shell crab fisheries, incorporating such biological indicators into management frameworks could also support sustainable resource use and enhance the resilience of lagoon ecosystems under increasing anthropogenic and climatic pressures.

ABSTRACT

Arnebia euchroma (is locally known as *Hava Chobeh*) is a native plant of Iran and has a valuable place in traditional Iranian medicine. *A. euchroma* is used to treat many problems such as inflammation, joint pain, uterine infections, fungal and bacterial infections, and wound healing and burns. One of the limitations in cultivating this valuable plant is its low germination percentage and uneven germination. In recent years, the use of LED light sources has increased the germination of medicinal plants. Therefore, in this study, LED light treatments were used to improve the germination and growth characteristics of the *A. euchroma* plant. The present study was conducted at the Faculty of Agriculture and Natural Resources, University of Mohaghegh Ardabili (IRAN) in 2025. The experiment was conducted in a completely randomized design with 4 treatments and 4 replications. Four light treatments were used as follows: 100% white light, 100% blue light, 100% red light, and a combination of blue and red light (50:50). Germination indices (germination percentage and germination rate), morphological (seedling dry weight, root length, and stem length), and biochemical (photosynthetic pigments, total carbohydrates, and total protein) were examined. The findings indicated that red light enhanced various germination and growth metrics of the *A. euchroma* plant. When analyzing the biochemical traits of 30-day-old seedlings of the *A. euchroma* plant, it was observed that combining blue and red light significantly elevated the levels of photosynthetic pigments, total carbohydrates, and total protein. Therefore, the use of red LED during seedling stages was considered an effective treatment to improve germination and growth characteristics. Additionally, according to the findings, the *A. euchroma* plant exhibited different reactions to light wavelengths during later growth stages, with the blue and red light combination promoting higher rates of photosynthesis and increasing carbohydrate and protein levels.

Keywords: Germination percentage, Germination rate, Photosynthetic pigments, Total carbohydrates, Total protein

INTRODUCTION

Medicinal plants, as an important part of natural and biological diversity, have played a significant role in the traditional medicine of human societies and in improving human health (Buso et al., 2020). As a rich source of bioactive compounds, these plants possess numerous therapeutic properties that have been beneficial in the prevention and treatment of various diseases. One of the valuable medicinal species in traditional Iranian medicine is the plant *Hava Chobeh* or *Hochoe*, which is known as Abu Khalsa in the book of Abu Ali Sina's Canon (Mizani et al., 2021).

Hava Chobeh is known scientifically as *Arnebia euchroma* L. and belongs to the *Boraginaceae* family. *A. euchroma* is a hairy and perennial plant that is found mainly in the temperate and sub-alpine regions of the western Himalayas, the subtropical regions of North Africa, and parts of Central Asia, especially Iran, Afghanistan, and India (Kumar et al., 2021).

The leaves and roots of this plant have been widely used in the traditional systems of various communities as an antimicrobial and anti-inflammatory medicine in the treatment of chronic diseases (Chawla et al., 2021). Phytochemical studies have shown that the roots of this plant (Fig. 1) contain a natural phytochemical compound called naphthoquinone, such as shikonin, phenolic compounds, and their derivatives, which act as an anticancer, antibacterial, antifungal, and antioxidant drug (Kazybekov et al., 2024).

Population ecology reports have shown that overexploitation of this plant has placed it in the group of endangered species (Kumar et al., 2021). To address the crisis of the extinction of medicinal plants, the use of cultivation techniques for endangered plants can help preserve and restore these valuable resources (Catana et al., 2020).

Previous studies have indicated that the germination of many medicinal plants is related to the spectrum (quality or color) of light, and the combination of specific wavelengths of light has had a significant effect on increasing germination and growth of some species (Sena et al., 2024). Today, LEDs (light-emitting diodes) have replaced traditional light sources as a source of various colored light with many advantages. With LEDs, the quality of light can be easily adjusted, and growers and researchers can achieve different physiological responses in plants according to their specific goals (Wang et al., 2021).

Recent studies have revealed that a high proportion of red light is essential for seed germination and seedling establishment of *Matricaria chamomilla* L. (Bączek-Kwinta and Michałek, 2025). Also, the application of red light to pepper seeds (*Capsicum annuum* L.) has improved the germination rate, emergence and growth of radicles (Zaghdoud et al., 2023). Several studies have shown the importance of light spectra on the germination of plant species, however, it has been found that the germination and growth responses of plants to color spectra depend on the species (Soufi et al., 2025). Therefore, considering the medicinal importance of the *A. euchroma* plant and its uncontrolled harvesting from nature, the present study aimed to use different light spectra to improve the germination and growth of this valuable species.

Figure 1. The roots of *Arnebia euchroma* L. plant collected from mountainous areas of Ardebil, Iran

MATERIAL AND METHOD

The present study was conducted at the Faculty of Agriculture and Natural Resources, University of Mohaghegh Ardabili (Iran) in 2025. The experimental treatments included 4 light treatments (4 light chambers) as follows: 100% white LED light or W (wavelength 420-680 nm), 100% blue LED light or B (wavelength 460-470 nm), 100% red LED light or R (wavelength 620-630 nm), and a combination of blue and red LED light or BR (with a ratio of 50:50). Day and night temperatures were set at 20°C and 16°C, respectively. The relative humidity of the light chambers was set at 60% and the photoperiod in all light chambers was 16 hours of light. The photosynthetic photon flux density (PPFD) measured above all Petri dishes and plants was 20 $\mu\text{mol}/\text{m}^2 \text{ s}$. LED lamps (16 W, 1200 $\times$ 24 mm) were purchased from Pars Shahab Company, Iran. Each panel contained 96 LED lamps. The voltage, current, and frequency were AC 85-220 V, 100 mA, and 60.50 Hz, respectively.

The seeds of *Arnebia euchroma* L. were collected from the mountainous areas of Ardabil, Iran. Seeds were disinfected using sodium hypochlorite solution (2%) for 5 minutes and placed in a Petri dish containing wet filter paper. For each treatment, 4 Petri dishes were considered, and 25 seeds were placed in each Petri dish (a total of 100 seeds for each treatment). Then the petri dishes were transferred to light chambers.

Germination indices were evaluated by radicle emergence (2 mm in length) for 21 days based on the following formulas:

$$\text{Germination Percentage (GP)} = \frac{\text{Total number of germinated seeds}}{\text{Total number of seeds per assay}} \times 100$$

$$\text{Speed of Germination (SG)} = \frac{n_1}{d_1} + \frac{n_2}{d_2} + \frac{n_3}{d_3} + \dots + \frac{n_i}{d_i}$$

In this formula, n is the number of germinated seeds and d is the number of days.

Morphological indices were measured in 7-day-old seedlings. In each experimental replicate, 10 seedlings were evaluated. Morphological traits included seedling dry weight (DW), stem length (SL), and root length (RL). To measure dry weight (g), a digital laboratory balance (Semi-Micro Analytical Balances GR-200 model, A&D, Japan, with an accuracy of 0.0001 g) and an oven (at 40°C for 48 hours) were used. A ruler was utilized to measure stem length (cm) and root length (cm).

Then, the seedlings were grown in plastic pots containing peat moss and perlite (1:1) and placed in the same light chambers. The *A. euchroma* plants were evaluated for biochemical indices after 4 weeks. Photosynthetic pigments were measured at 470, 645, and 662 nm using a spectrophotometer (model SP-UV 200, Spectrum Instruments Limited, Australia). The concentration of photosynthetic pigments (µg/g fresh weight) was calculated using the following formulas (Lichtenthaler and Buschmann, 2005):

$$\text{Chlorophyll a} = C_a \text{ (}\mu\text{g/ml)} = 11.24 \times A_{661.6} - 2.04 \times A_{644.8}$$

$$\text{Chlorophyll b} = C_b \text{ (}\mu\text{g/ml)} = 20.13 \times A_{644.8} - 4.19 \times A_{661.6}$$

$$\text{Total carotenoids} = C_{(x+c)} \text{ (}\mu\text{g/ml)} = \frac{(1000 \times A_{470} - 1.90C_a - 63.14C_b)}{214}$$

Total carbohydrate content was measured using anthrone reagent at a wavelength of 630 nm. A glucose standard curve was used to calculate glucose equivalents (mg/g fresh weight) in each sample (Omokolo Doumou et al., 1996). Coomassie Brilliant Blue reagent was used to measure total protein content. The absorbance of the samples was read at a wavelength of 595 nm using a spectrophotometer. The total soluble protein content was calculated in mg/g fresh weight using a Bowen serum albumin (BSA) standard curve (Bradford, 1976).

This experiment was conducted in a completely randomized design with 4 replications. Data analysis was performed using SAS software version 9.1. Means were compared using Duncan's multiple range test at a 5% probability level. Graphs were drawn using Excel software.

RESULTS AND DISCUSSION

According to the results of the present study, light quality significantly affected the germination percentage and speed of germination. Comparison of the mean data showed that blue light treatment (B) reduced seed germination. In contrast, red LED light (R) significantly increased the GP and SG indices compared to other treatments (Fig. 2A and 2B).

Previous studies have indicated that increasing the germination percentage and germination speed are two important factors in improving the initial growth of seedlings, achieving uniform coverage in fields, increasing the ability to compete with weeds, etc. Accordingly, the application of treatments to improve the germination of plant seeds, especially in medicinal plants, can be fruitful with the aforementioned goals. Medicinal plants have been able to ensure their survival for many years by having a dormancy mechanism in their seeds. However, the presence of dormancy in medicinal plant seeds often led to great problems for researchers and breeders (Jamnani et al., 2023). Light not only provides energy for photosynthesis but also regulates the morphological development of plants. Some plant growth and development processes, such as germination, seedling development, and flowering induction, are affected by light. In the present study, although the B light treatment reduced the germination percentage, the application of R light enhanced germination. Furthermore, these results indicate that the seeds of the *A. euchroma* plant respond differently to light quality. According to the present study, in the experiments of Wang et al., the application of red light produced a similar result in the medicinal plant *Momordica charantia* L. (Wang et al., 2021). Furthermore, in the study of Pardo et al. (Paniagua Pardo et al., 2015), red light significantly increased the germination speed in *Brassica oleracea* L.

The results revealed that the growth characteristics (seedling dry weight, stem length, and root length) of the *A. euchroma* were significantly affected by LED treatments. Based on the results of the comparison of the mean data, the red light treatment (R) significantly increased the seedling dry weight (0.0899 g), stem length (4.125 cm), and root length (6.45 cm) compared to other light treatments. Also, the weakest growth characteristics were observed in the blue light treatment (B). In the stem length index, the combination of blue and red light (BR) was similar to the W light (Fig. 2C, 2D, and 2E).

Changes in light quality and quantity can affect the efficiency of photosynthesis and indirectly the availability of carbohydrates and energy for growth. Accordingly, the dry weight of the seedling of the *A. euchroma* increased under the influence of red light (R) at the seedling stage, as previously observed in *Lactuca sativa* L. (Sharma et al., 2024) and *Triticum aestivum* L. (Li et al., 2022). On the other hand, red light often causes elongation of the stems and roots. These effects have been observed in some plant species. It seems that the application of red light can facilitate shoot growth by increasing primary root growth and water and nutrient uptake (Solano et al., 2020). In addition, it has been reported that phytochromes regulate primary root length through red light (Li et al., 2022). It appears that shoot elongation in plants can vary significantly based on both the plant species and the specific growth stage. This variation is influenced by the interactions between blue/red light receptors and phytochromes, which can either promote or hinder growth. (Solano et al., 2020).

According to the results, light treatments were significantly effective on the content of photosynthetic pigments, total soluble carbohydrate, and total soluble protein. Blue light treatment (B) significantly reduced the content of chlorophyll a. Two light treatments, white (W) and red (R), showed similar results in the content of photosynthetic pigments. On the other hand, the combined treatment of blue and red light (BR) led to a significant increase in the content of photosynthetic pigments. In the indices of total carbohydrate content (176.36 mg/g fresh weight) and total protein (34.9208 mg/g fresh weight), the combined treatment of blue and red light (BR) indicated a greater effect than the other treatments in increasing the aforementioned indices. In addition, blue light treatment reduced the content of carbohydrate and protein (Fig. 3A, 3B, and 3C).

Figure 2. The effect of light qualities on germination and growth characteristics of the *Arnebia euchroma* L. plant. (A), germination percentage (GP), (B), speed of germination (SG), (C), seedling dry weight (DW), (D), stem length (SL), and (E), root length (RL). Different letters indicate significant differences determined using Duncan's multiple range test ($p < 0.05$). Error bars represent $\pm$ SE, $n = 4$

Studies have shown that the effect of spectral changes on growth and biochemical parameters (in addition to plant species) is likely to depend on the growth stage of plants. In the present study, biochemical indices were increased by the application of a combination of blue and red light (BR). Red and blue light constitute the largest share of the total light received by plants and are considered to be the most influential wavelengths. Chlorophyll and carotenoids cause photosynthesis in plants by absorbing the blue and red light spectrum (Li et al., 2022). In addition, blue light is involved in chlorophyll formation and chloroplast development. It has been reported that light quality is an important factor affecting the synthesis and accumulation of primary metabolites such as carbohydrates and proteins (Li et al., 2022). In this study, the content of total carbohydrates and soluble protein under BR light treatment was the highest. In some plant species, such as *Momordica charantia* L. (Wang et al., 2021), an increase in total carbohydrate content under BR light has been reported, which is due to the intervention of red and blue light in improving plant photosynthesis, carbohydrate biosynthesis, and increasing growth (Sharma et al., 2024). Although proteins affect photosynthetic performance, they have been less investigated in light quality studies. Similar to the results of this study, total protein content increased under BR treatment in *Cunninghamia lanceolata*. It has been reported that blue light has higher photon energy and can play a role in the synthesis of macromolecules such as protein. Additionally, blue light increases pyruvate kinase protein in the glycolysis pathway (Wang et al., 2021).

Figure 3. The effect of light qualities on biochemical characteristics of the *Arnebia euchroma* L. plant. (A), photosynthesis pigments, (B), total soluble carbohydrate, (C), total soluble protein. Different letters indicate significant differences determined using Duncan's multiple range test ($p < 0.05$). Error bars represent $\pm SE$, $n = 4$

CONCLUSION

This study investigated the germination, growth, and biochemical characteristics of the *A. euchroma* plant under LED sources with different light spectra. Treatment of *A. euchroma* seeds with red light (R) enhanced germination. It also increased seedling dry weight, stem length, and root length. In contrast, blue light (B) treatment reduced seed germination and severely affected growth. In the later growth stages, the response of *A. euchroma* plants to light spectra was different from that of the seedling stages. Thus, under BR light treatment, the highest content of photosynthetic pigments, total carbohydrate content, and total protein content was obtained. This study provided a basis for manipulating the light spectrum and selecting the appropriate ratio of blue and red light according to the goals of the breeders.

ABSTRACT

This study aimed to investigate the effects of chitosan-coated iron oxide nanoparticles and silver nanoparticles on the morphological traits and secondary metabolites of the ornamental plant snapdragon (*Antirrhinum majus*) under greenhouse conditions. Treatments were arranged in a factorial experiment based on a completely randomized design with four replications, involving four concentration levels (0, 50, 100, and 150 mg/L for silver nanoparticles and μM for chitosan-coated iron oxide nanoparticles). The measured parameters included stem diameter, bud diameter, fresh weight of aerial parts, number of lateral branches, chlorophyll content, total sugars, flavonoids, and antioxidant capacity (DPPH). Analysis of variance revealed that the main effects of nanoparticles on the fresh weight of aerial parts, stem diameter, and number of lateral branches were significant at the 1% probability level, and on bud diameter at the 5% level. The interaction effects of nanoparticles on total sugars, flavonoids, and DPPH were also significant at the 1% level. The highest fresh weight and number of lateral branches were observed in the treatment with 100 μM chitosan-coated iron oxide nanoparticles and 50 mg/L silver nanoparticles, while the highest total sugars, flavonoids, and antioxidant capacity were recorded with 150 mg/L silver nanoparticles and 150 μM chitosan-coated iron oxide nanoparticles. These findings confirm the potential of nanotechnology in enhancing the quality and antioxidant properties of ornamental plants and suggest that future research should focus on optimizing concentrations and evaluating long-term effects.

Keywords: Flavonoids, Snapdragon, Total Sugars, Nanoparticles.

INTRODUCTION

Snapdragon (*Antirrhinum majus*), a perennial plant from the *Scrophulariaceae* family native to the Mediterranean region, is highly valued in the floriculture and ornamental industries due to its colorful flowers and attractive structure. This plant is cultivated as an annual in cold regions and as a biennial in areas with mild winters, with its growing demand in global markets highlighting the need for innovative methods to improve its quality and performance. In recent decades, nanotechnology has emerged as a pioneering field of modern science, opening new horizons in sustainable agriculture. Nanoparticles, with their nanometer-scale size and high surface area, have become key tools for enhancing plant growth, controlling pests, and increasing resistance to environmental stresses. Among these, chitosan-coated iron oxide nanoparticles ($\text{Fe}_3\text{O}_4@\text{Chitosan}$ NPs) and silver nanoparticles (AgNPs) stand out due to their targeted nutrient delivery and strong antimicrobial properties, respectively. The application of nanoparticles as pesticides, protective agents, antimicrobials, and nutritional supplements has revolutionized agriculture. Recent studies (e.g., 2024 research on ornamental plants) have shown that silver nanoparticles at low concentrations (e.g., 60 ppm) can

significantly increase fresh weight, stem length, and anthocyanin production by stimulating antioxidant enzyme activity, particularly in a time-dependent manner (Behzad *et al.*, 2024). Additionally, silver nanoparticles at low concentrations have been found to enhance plant growth and boost the production of secondary metabolites like flavonoids, improving antioxidant properties (Mirzaei, & Kiarostami, 2022), which could benefit snapdragon quality. On the other hand, chitosan-coated iron oxide nanoparticles, due to their biocompatibility and ability to prevent particle aggregation, have wide applications in managing environmental stresses. A study on peppermint (*Mentha piperita*) under drought stress showed that increasing concentrations of chitosan-coated iron oxide nanoparticles improved chlorophyll fluorescence and photosynthetic indices (Giglou *et al.*, 2022). Chitosan, a natural polymer derived from chitin, not only enhances nanoparticle stability but also reduces their potential toxicity, enabling safer use in biological systems. These findings suggest that combining iron and silver nanoparticles with chitosan coating could offer a novel approach to improving snapdragon growth, stress resistance, and its medicinal and ornamental applications. This study examines the synthesis, mechanism of action, and potential of these nanoparticles in enhancing snapdragon performance, with an emphasis on their antimicrobial effects and growth stimulation.

MATERIALS AND METHODS

This research was conducted using snapdragon seeds purchased and cultivated in the greenhouse of the Faculty of Agriculture and Natural Resources, University of Mohaghegh Ardabili. Treatments included two types of nanoparticles; silver nanoparticles and chitosan-coated iron oxide nanoparticles; at four concentration levels: 0 (control), 50, 100, and 150 mg/L for silver nanoparticles, and 0 (control), 50, 100, and 150 μ M for chitosan-coated iron oxide nanoparticles. Treatments were applied via foliar spraying in three growth stages of the plants. Seeds were initially sown in seedling trays and, after germination and reaching the four-leaf stage, transplanted into pots containing a 1:1:1 volumetric mixture of organic matter, sand, and garden soil. The experimental design was a factorial arrangement based on a completely randomized design with four replications. Each experimental unit included a sufficient number of plants to ensure reliable statistical data. To assess treatment effects, morphological and growth parameters were measured. The number of lateral branches was recorded using a counting unit. Stem and bud diameters were determined using a caliper with 0.1 mm precision. Fresh weight of aerial parts was measured with a balance accurate to 0.001 g. Total flavonoid content was assessed using the method of Krizek *et al.* (1998) with a spectrophotometer. For total carbohydrate measurement, 0.2 g of green plant tissue was combined with 10 mL of 95% ethanol in a sealed test tube and heated in a water bath at 80°C for 1 hour. After cooling, 1 mL of the sample was mixed with 1 mL of 5% phenol and 5 mL of 98% sulfuric acid, and absorbance was read at 483 nm using a spectrophotometer.

RESULTS

Analysis of variance indicated that the main effects of the treatments (chitosan-coated iron oxide nanoparticles and silver nanoparticles) were significant, except for bud diameter, which was significant at the 5% probability level. The fresh weight of aerial parts, stem diameter, and number of lateral branches were significant at the 1% level (Table 1).

Table 1. Analysis of Variance of the Effects of Silver Nanoparticles and Chitosan-Coated Iron Oxide Nanoparticles at Different Concentrations on Morphological Traits of Snapdragon

Sources of Variation	DF	Stem Diameter	Aerial Parts Fresh Weight	Lateral Branches Number	Bud Diameter	*, **, and ns

Error	48	0,003	0,126	8,48
Coefficient of Variation	—	8,06	8,745	7,265

*, **, and ns indicate significance at the 5%, 1%, and non-significant probability levels, respectively.

FRESH WEIGHT OF AERIAL PARTS

The results revealed that chitosan-coated iron oxide nanoparticles at 100 µM and silver nanoparticles at 50 mg/L had a significant effect on the morphological traits of snapdragon. The highest plant height, number of first-order lateral branches, and fresh weight of aerial parts were observed in plants treated with 100 µM chitosan-coated iron oxide nanoparticles and 50 mg/L silver nanoparticles (Figure 1A).

STEM DIAMETER

The results showed a significant effect of chitosan-coated iron oxide nanoparticles on stem diameter. The highest stem diameter was observed in plants treated with 50 μ M chitosan-coated iron oxide nanoparticles and 150 mg/L silver nanoparticles, while the lowest was found in untreated control plants (Figure 1B).

Figure 1. Interaction effects of chitosan Coated IONPs and AgNPs on Fresh Weight of Aerial Parts (A) and Stem Diameter (B) of Snapdragon.

BUD DIAMETER

Comparative analysis of morphological traits indicated that chitosan-coated iron oxide nanoparticles and silver nanoparticles had a significant effect on bud diameter. The highest bud diameter was observed in plants treated with 150 mg/L silver nanoparticles and 100 μ M chitosan-coated iron oxide nanoparticles, while the lowest was found in untreated control plants (Figure 2A).

NUMBER OF LATERAL BRANCHES

The analysis of the effects of chitosan-coated iron oxide nanoparticles and silver nanoparticles on the number of lateral branches showed that the highest number was achieved in the treatment with 100 μ M chitosan-coated iron oxide nanoparticles and 50 mg/L silver nanoparticles (Figure 2B).

Figure 2. Interaction effects of chitosan Coated IONPs and AgNPs on Bud Diameter (A) Number of Lateral Branches (B) of Snapdragon.

TOTAL SUGARS

The analysis indicated that total sugar content in snapdragon varied with increasing concentrations of silver nanoparticles and chitosan-coated iron oxide nanoparticles. The lowest value was observed in the control treatment (0 mg/L silver nanoparticles and 0 μM chitosan-coated iron oxide nanoparticles), while the highest was recorded with 150 mg/L silver nanoparticles and 150 μM chitosan-coated iron oxide nanoparticles. Intermediate concentrations, such as 50 mg/L silver nanoparticles with 100 μM chitosan-coated iron oxide nanoparticles, also showed an increase in total sugars (Figure 3A).

FLAVONOIDS

The results showed that flavonoid content in snapdragon was influenced by varying nanoparticle concentrations in treatments. The lowest flavonoid content was observed in the control (0 mg/L silver nanoparticles and 0 μM chitosan-coated iron oxide nanoparticles), while the highest was achieved with 150 mg/L silver nanoparticles and 150 μM chitosan-coated iron oxide nanoparticles. Intermediate treatments, such as 50 mg/L silver nanoparticles with 100 μM chitosan-coated iron oxide nanoparticles, exhibited a significant increase in flavonoids, whereas 150 μM chitosan-coated iron oxide nanoparticles without silver nanoparticles resulted in a decrease, highlighting the importance of balanced concentrations (Figure 3B).

Figure 3. Interaction effects of chitosan Coated IONPs and AgNPs on Total Sugars (A) Flavonoids (B) of Snapdragon.

DPPH

The comparative analysis of mean data revealed that increasing concentrations of chitosan-coated iron oxide nanoparticles generally enhanced antioxidant capacity. The greatest treatment effect was observed from 0 to 150 μM chitosan-coated iron oxide nanoparticles combined with 50 mg/L silver nanoparticles. Additionally, the interaction of both treatments at 100 μM chitosan-coated iron oxide nanoparticles and 100 mg/L silver nanoparticles yielded the highest antioxidant capacity (Figure 4).

Figure 4. Interaction effects of chitosan Coated IONPs and AgNPs on DPPH.

DISCUSSION

The results of this study demonstrated that the application of chitosan-coated iron oxide nanoparticles and silver nanoparticles can significantly affect the morphological and biochemical traits of snapdragon. These findings align with previous reports on the efficacy of nanoparticles in improving growth characteristics and quality of ornamental plants (Anushi *et al.*, 2023; Behzad *et al.*, 2024). Silver nanoparticles, particularly at low concentrations such as 50 ppm, promoted growth, increased the number of lateral branches, and enhanced the fresh weight of aerial parts, likely due to

their role in stimulating antioxidant enzyme activity and reducing oxidative stress (Liu, *et al.*, 2020). These nanoparticles may also influence plant signaling pathways by regulating the expression of growth-related genes (Rasheed *et al.*, 2022). Conversely, chitosan-coated iron oxide nanoparticles, with their biocompatible properties and gradual iron release, particularly at 100 μ M, contributed to increased chlorophyll, stem diameter, and fresh weight. This could be attributed to improved iron availability, a key element in chlorophyll synthesis and plant metabolism (Giglou *et al.*, 2022). The chitosan coating enhances absorption and reduces potential nanoparticle toxicity, playing a significant role in their effectiveness (Shi *et al.*, 2020). The significant increase in total sugars and flavonoids in combined treatments with high nanoparticle concentrations indicates their interactive effect on secondary metabolite pathways. Flavonoids, important defensive compounds in plant systems, are influenced by environmental factors and stimulants like nanoparticles, potentially through the activation of phenylpropanoid pathways or increased activity of PAL and CHS enzymes (Selvakesavan *et al.*, 2023). These results are consistent with findings from another study on snapdragon by Pourbeyrami Hir and Sardari (2025), which reported significant improvements in vegetative growth, flower diameter, number of lateral branches, and total phenol content with combined use of chitosan-coated iron oxide and silver nanoparticles at concentrations of 100-150 μ M and 50-150 mg/L, respectively. Overall, these findings not only confirm the potential of nanoparticles in enhancing ornamental plant quality but also open new avenues for sustainable production, reduced chemical fertilizer use, and increased medicinal value of plants. Given the growing adoption of nanotechnology in precision agriculture, future research should focus on targeted, safe, and cost-effective nanoparticle applications.

CONCLUSION

This study demonstrated that the combined application of chitosan-coated iron oxide and silver nanoparticles, particularly at moderate to high concentrations, can effectively improve growth and physiological traits in Snapdragon. These nanoparticles enhanced plant height, branching, and flowering while also increasing chlorophyll fluorescence and phenolic compounds. These findings support the strategic use of biocompatible nanoparticles in ornamental plant management as a promising approach for boosting performance and resilience, particularly within sustainable and eco-friendly agricultural systems.

ABSTRACT

The process of coagulation and flocculation is a common method used in the water treatment process. Coagulants used in this study were chemical coagulants i.e. Aluminum Sulfate ($\text{Al}_2(\text{SO}_4)_3$) as reference of chemical coagulant and biocoagulants (i.e. pineapple peels, *Araucaria hyterophylla*). The aim of this study was to examine the impact of biocoagulants on their performance, which is marked by the decrease in turbidity, suspended matter (SM), and electrical conductivity (EC). A wide range of coagulant dosage (0.1– 0.4 g/500 mL) and synthetic turbid water at pH 8 were used to evaluate the coagulation process. The results showed that the highest turbidity removal for *Araucaria hyterophylla* and AS achieved at the dosage of 0.1 g as much as 84.97% and 97.62 % respectively and the optimal dose of pineapple peels was 0.4g.

Keywords: Water treatment, coagulation-flocculation, turbidity removal, biocoagulant.

INTRODUCTION

Because of cost savings, environmental issues of synthetic organic polymers and inorganic chemical products it is of interest to use natural materials. Natural polyelectrolytes are completely free of toxicity, naturally biodegradable and locally accessible. The coagulants are derived from mineral products, micro-organisms, animals, plants, vegetation (Mogbo et al., 2020) Natural polymers cannot always be successful and should, like any other coagulant substance, be investigated on a case-to - case basis.

Extracts made from *Moringa Oleifera* seeds, for example, reduced turbidity and suspended solids in raw water by 80 to 99.5 percent (Putra, R. S et al., 2020). *Moringa Oleifera* decreased from water 90 percent to 99 percent of bacteria and 90 percent of cercariae. Nirmali seed can be used as a coagulant to extract turbidity, bacteria, and viruses from water [Ebeling, James M et al., 2003, Vishali, S et al., 2015).

The extracted seed of chestnut and corn species could also be used as natural coagulants to eliminate the turbidity (Hendrawati, Het al.,2013).

Chitosan can be used as a coagulant and the mechanisms for the reduction of turbidity have generally been charged neutralization due to positive amino grouping and bridging (Muralimohan, Net al., 2014).

It was found that cornstarch and cationic waxy cassava can be used as turbidity recovery coagulants and primarily as adsorption and bridge action mechanisms (Okuda, Tetsuji, et al., 2008, Srawaili, N. J. B. I. T. B. 2008) respectively, that cactus extracted polymer can be employed as the primary turbidity recovery coagulant and its efficiency is stated (Aldosky, H. Y. Y et al., 2011).

MATERIALS AND METHODS

Bio Coagulant Preparation

In this study, pineapple peels and the leaves of *Araucaria hyterophylla* was used as a natural coagulant/flocculent. The leaves of *Araucaria hyterophylla* were collected from the University of Skikda and ananas comosus were purchase from the town of Skikda, Algeria. To remove dust, impurities, the biomaterials were cleaned with distilled water.

The biomaterials were cut into small pieces, and then crushed using a domestic grinder. The solids were used as a raw coagulant to treat turbid water without any chemical pre-treatment.

A. Experimental Procedure

Synthetic turbid water was prepared by adding clay into tap water. The suspension was stirred for 1 h to achieve a uniform dispersion of clay particles [7]. The values of turbidity, pH, electrical conductivity (EC) and suspended matter in raw water were shown in table 1.

Table 1. Initial conditions of raw water

Parameters	Values of turbid water	
	Biocoagulant	chemical coagulant
pH	8	8.2
Turbidity (NTU)	53	55.2
electrical conductivity ($\mu\text{S}/\text{cm}$)	943	900
suspended matter (mg/l)	0.05	0.06

At the start of the experiment, the contents of the tank were mixed to a uniform initial turbidity, temperature, and pH values. All the experiments were carried out at a room temperature of 20 °C. Jar test is the most widely used experimental methods for coagulation-flocculation. The conventional jar-test technique was used. A six-beaker jar-test apparatus (Lobivond Model) was used to simulate the coagulation/flocculation process. The synthetic turbid water was treated using coagulants (i.e. chemical and biocoagulant) at different dosages (i.e. 0.1; 0.2; 0.3 and 0.4 g) in 500 mL solution. The solution and the coagulant were mixed together at 160 rpm for 5 min. followed by slow mixing at 45 rpm about 25 mins and the formed flocs were allowed to settle for 1h. After settling, the performance of biocoagulant was evaluated by using turbidity removal and suspended matter removal.

The Suspended matter removal efficiency (SM %) and turbidity removal efficiency (TUR %) were calculated using Eqs.1 and 2, respectively.

$$SM (\%) = \frac{SM_0 - SM_F}{SM_0} \times 100$$

$$R(\%) = \frac{TUR_0 - TUR_F}{TUR_0} \times 100$$

SM_0 and SM represent the initial and final SM (mg/L) of wastewater, respectively and, similarly, TUR_0 and TUR represent the initial and final supernatant turbidity of turbid water (NTU).

RESULTS AND DISCUSSIONS

The performance test of biocoagulants were prepared by initial artificial turbid water was 53 NTU for pineapple peels and araucaria heterophylla and 55.2 NTU for AS. The final turbidity can be affected by varying amounts of pineapple peels, araucaria heterophylla, and AS added to the solution. Addition of 0.1, 0.2, 0.3 and 0.4g of pineapple peels decreased respectively the turbidity as much as 23, 20, 19,2 and 17,8 NTU and araucaria heterophylla also decreased the turbidity to 8.04, 8.24, 9.26 and 9.50 NTU respectively.

While different results showed when AS was used in similar dosages. The decrease of turbidity achieved were as much as 1.31, 6.96, 10.5 and 13.1 NTU, respectively. Figure 1 shows the turbidity removal when using AS and pineapple peels and araucaria heterophylla as coagulant. The turbidity removal of pineapple peels at 0.1, 0.2, 0.3 and 0.4g were 56.6, 62.26, 63.77 and 66.41 %, respectively. As well as the turbidity removal of araucaria heterophylla were 84.97, 84.59, 82.69 and 83.01 %, respectively.

AS removed turbidity at dosages of 0.1, 0.2, 0.3, and 0.4g respectively with 97.62, 87.39, 80.97, and 76.26%, suggesting that there is a difference in optimal dose for pineapple peels, araucaria heterophylla and AS to remove turbidity. The increase of AS and araucaria heterophylla dosages was followed by the decrease of turbidity removal. On the contrary, the increase of pineapple peels dosage was followed by the increase of turbidity removal.

Figure 1. Turbidity removal (%) from synthetic turbid water after treatment.

The excessive dosage of chemical coagulants and araucaria heterophylla has the effect of decreasing SM removal. Increasing the Pineapple peels dosage increased the SM removal of the solution.

The optimum dosage of AS and araucaria heterophylla was 0.1 g to increase the SM removal to 85.5 % and 84.4 % respectively. The maximum elimination of suspended matter occurs at low doses of AS and araucaria heterophylla. On the other hand, the optimal dosage of Pineapple peels to eliminate 78.4 % of suspended matter was 0.4 g.

The coagulation process occurs during rapid mixing. By interacting with all colloidal surface particles, the polymers of those coagulants will ensure that the end chain is not attached, causing the flocculation

process to occur. The process of flocculation occurs during slow stirring. The microflocs which form during the coagulation process bind together to form a larger floc. That was how the coagulants can reduce the suspended mater and the turbidity

Figure 2. Suspended matter removal of synthetic turbid water after treatment using chemical coagulants and biocoagulants.

Table 2 shows the electrical conductivity (EC) of artificial turbid water after treated by chemical coagulants and biocoagulants. The EC shows how much materials were dissolved in solution. EC was calculated from the measurement of the resistance of an electrolyte where the conductivity and resistance were inversely related (Aldosky, H. Y. Y et al.,2011).

TABLE 2. Electrical conductivity ($\mu\text{S}/\text{cm}$) of synthetic turbid water after treatment using chemical coagulants and biocoagulants.

Dosage (g/500mL)	Chemical coagulant	Biocoagulant	
	Aliminium sulfate	pineapple peels	araucaria hyterophylla
0.1	958	945	950
0.2	1116	945	961
0.3	1176	955	972
0.4	1260	963	982

When AS, pineapple peels and araucaria hyterophylla were dissolved in a solution at pH ~ 8 , these materials were expected to produce ions in solution and lead to increase the EC value.

The presence of mineral elements charged macromolecules and other ionic compounds in moringa was dissolved or dissociated into the turbid water caused a high increase of EC (Magaji, U. F et al., 2015)

TABLE 3. Comparison of efficiency of natural coagulant

Natural coagulant	Turbidity removal	Suspended mater removal
pineapple peels	66.41 %	78.4 %
araucaria hyterophylla	84.97 %	84.4 %

Table 3 presents comparative results of two natural coagulants; pineapple peels and araucaria hyterophylla in the reduction of turbidity and suspended mater with their optimum dosage. From the table 3, it is clear that, out of two coagulants araucaria hyterophylla is more efficient in reduction of SM of 84.4% and gave the highest turbidity reduction of 84.97%.

CONCLUSIONS

The removal of turbidity from a synthetic turbid water sample treated with biocoagulants has been evaluated.

The performance of the biocoagulants was also compared with the AS as a reference. The addition of 0.1 g araucaria hyterophylla decreased the turbidity, SM, and EC successfully. The turbidity and suspended mater decreased by up to 84.97 % and 84.4 % respectively. The increasing of EC cannot be avoided while using AS as coagulant due to the presence of organic matter in this material. However, the use of biocoagulant did not bring the toxic effect and was not harmful to human health.

ABSTRACT

Medicinal plants have played an important role in the treatment of diseases for thousands of years and continue to be a fundamental resource for the pharmaceutical industry today. Secondary metabolites synthesized by plants, such as alkaloids, tannins, flavonoids, and phenolic compounds, are known for their therapeutic effects and are widely used in traditional medicine. In particular, traditional medical systems in countries such as China, India, Japan, and Thailand are largely based on these plants. In this context, bitter melon (*Momordica charantia* L.) of the Cucurbitaceae family stands out not only for its medicinal properties but also for its use as an ornamental plant. Thanks to its fast-growing, twining stems and striking foliage, it is frequently preferred as a decorative climbing plant in landscape architecture. This species is an annual climber that grows in tropical and subtropical regions and is notable for its rich content of vitamins (C, A, B complex), minerals (iron, calcium, phosphorus, potassium, zinc, magnesium), and β -carotene. In this study, the biochemical components and volatile organic compounds (VOCs) of bitter melon fruits grown under the ecological conditions of Adana were determined. The analyses included sugars, organic acids, total phenolic compounds, antioxidant capacity (DPPH) and the volatile compound profile using GC-MS. Glucose (367.53 mg/100 g FW) and fructose (229.43 mg/100 g FW) were identified as the dominant sugars, while succinic acid (221.43 mg/100 g FW) and citric acid (55.78 mg/100 g FW) were the predominant organic acids. The ascorbic acid content was 10.50 mg/100 g FW, total phenolic content was 47.54 mg GAE/100 g FW, and antioxidant capacity was measured as 24.09% DPPH inhibition. Volatile compound analysis revealed that esters (48.18%), alcohols (34.59%), and aldehydes (4.43%) were the most abundant groups. Among the most prominent compounds were ethyl acetate (23.91%), ethanol (11.80%), 5-(hydroxymethyl)-2-furfural (3.39%), benzeneethanol (9.01%), and 2,3-dihydro-3,5-dihydroxy-6-methyl-4H-pyran-4-one (5.36%). These compounds contribute to the characteristic aroma and potential biological activities of the fruit. In conclusion, studies have shown that *M. charantia* possesses antidiabetic, anticancer, antioxidant, and antimicrobial properties. Its fruits, leaves, and seeds are traditionally used in medicine due to active compounds such as charantin, polypeptide-p (a plant insulin-like compound), and steroidal saponins. Furthermore, bitter melon is also regarded as a dual-purpose plant, serving as an ornamental climber in landscape designs: it can be cultivated in pots on balconies or on trellises and arbors in gardens, offering both medicinal and aesthetic value. Under Adana's ecological conditions, bitter melon fruit exhibits a rich biochemical and volatile profile, making it a promising candidate as a functional food, natural aroma source, and ornamental plant with pharmacological and landscape significance.

Keywords: Functional food, GC-MS, Organic acids, Ornamental plant, Sugars, Volatile compounds.

INTRODUCTION

Medicinal plants have long been recognized as crucial sources of therapeutic compounds and remain indispensable in modern pharmaceutical development. Secondary metabolites such as alkaloids, flavonoids, tannins, and phenolic compounds synthesized by plants exhibit diverse biological activities, including antimicrobial, antioxidant, antidiabetic, and anticancer effects. These properties have made medicinal plants a focal point in traditional medicine systems across Asia, particularly in China, India, Japan, and Thailand, and they continue to attract global scientific interest (Grover and Yadav, 2004; Basch et al., 2003). Among these species, bitter melon (*Momordica charantia* L.), a member of the Cucurbitaceae family, holds significant importance due to its rich phytochemical composition and multipurpose applications. *M. charantia* is a tropical and subtropical annual climbing plant characterized by vigorous vine-like growth, deeply lobed leaves, and bright yellow flowers. Traditionally, it has been widely consumed as both food and medicine in tropical and subtropical regions. The fruit contains diverse bioactive compounds such as polyphenols, flavonoids, and saponins, which are largely responsible for its pharmacological properties (Hsiao et al., 2013; Kubola and Siriamornpun, 2008; Shan et al., 2012). For example, aqueous extracts of the fruit are rich in phenolic compounds contributing to strong antioxidant activity (Kubola and Siriamornpun, 2008), while saponins have demonstrated anti-proliferative and hypoglycemic effects (Hsiao et al., 2013). In the food industry, the stability and bioactivity of these phytochemicals are strongly influenced by processing methods (Choi et al., 2012; Jin et al., 2018). Hot-air dehydration, for instance, has been shown to significantly reduce total phenolic content due to prolonged exposure to high temperatures (Jin et al., 2018). Moreover, the inherently bitter taste of *M. charantia* limits consumer acceptance. To mitigate bitterness, techniques such as blanching and the use of additives (sodium chloride, carboxymethyl cellulose, gum Arabic) have been applied, though these methods may compromise bioactive compounds, raise production costs, and reduce health benefits (Rashima et al., 2017). Beyond its medicinal and nutritional importance, *M. charantia* is also valued as an ornamental plant. Its vigorous twining stems and attractive foliage make it suitable for landscape use on trellises, pergolas, balconies, and garden fences, providing both aesthetic and ecological benefits (Kubola and Siriamornpun, 2008). Nutritionally, bitter melon fruits are rich in vitamins (C, A, B-complex), minerals (iron, calcium, phosphorus, potassium, zinc, magnesium), and bioactive compounds such as charantin, polypeptide-p, and steroidal saponins. These compounds play critical roles in regulating blood glucose levels and exhibit anti-inflammatory and anticancer properties (Ray et al., 2010). Additionally, the fruit contains phenolic compounds, flavonoids, and carotenoids that enhance antioxidant capacity and reduce oxidative stress (Horax et al., 2010). Recent studies have also focused on the biochemical composition and volatile organic compounds (VOCs) of *M. charantia*, as these attributes contribute to both its nutritional and aromatic profiles. VOCs, including esters, alcohols, aldehydes, and terpenes, are key determinants of the fruit's aroma. Advanced analytical tools such as gas chromatography–mass spectrometry (GC-MS) have enabled detailed profiling of these compounds, which may influence both sensory perception and bioactivity (Chowdhury et al., 2012). The biosynthesis of bioactive and volatile compounds is strongly affected by environmental factors. Thus, investigating plants under specific ecological conditions is essential. The Adana region, located in the eastern Mediterranean part of Türkiye, provides unique agro-climatic conditions characterized by high temperatures and long sunshine duration, which are favorable for tropical and subtropical crops such as bitter melon. These conditions may significantly influence the phytochemical and volatile compound profiles of the fruit.

The present study was conducted to comprehensively evaluate the biochemical composition and volatile organic compound profile of *M. charantia* cultivated under the ecological conditions of Adana. Specifically, analyses targeted sugars, organic acids, total phenolics, antioxidant capacity, monomeric anthocyanins, and volatile compounds using GC-MS. By integrating nutritional and aroma profiling, this research highlights the potential of bitter melon as a functional food, a natural aroma source, and an ornamental species. Beyond its well-documented medicinal value, this dual perspective emphasizes the role of *M. charantia* in both health-related applications and sustainable landscape design, where multifunctional plants with aesthetic and ecological benefits are increasingly sought.

MATERIALS AND METHODS

Plant Material

Fruit samples of *Momordica charantia* L. were collected from a commercial orchard located in the Sarıçam district of Adana province,

Method

Determination of total phenol

The total phenolic content of pulp was determined colorimetrically using Folin Ciocalteu's reagent (Spanos and Wrolstad, 1990). Results were described as mg of gallic acid equivalent/100 g of weight (mg/ GAE 100 g).

Determination of total antioxidant capacity

Radical scavenging activity of DPPH:(2,2-diphenyl-1-picrylhydrazyl): The procedure was performed as outlined by Brand-Williams (1995) with slight modifications as detailed by Polat et al. (2022).

Total monomeric anthocyanin content determination

For total anthocyanin analysis, the method described by Giusti and Wrolstad, (2001) was used with some modifications. Total anthocyanin determination was read at 510 nm and 700 nm in a spectrophotometer and calculation was made according to the following formula.

Absorbance = X = (510 nm pH 1 - 700 nm pH 1) - (510 nm pH 4.5 - 700 nm pH 4.5)

Anthocyanin content (mg/L) = (absorbance/ 29600 x 1) x 1000 x 445 x 20

Individual sugar and organic acid extraction and determination

Sugars and organic acids were extracted individually following the procedure described by Mikulic-Petkovsek et al. (2016). Homogenized, unfrozen fruit samples were placed in a test tube containing 4 mL of bi-distilled water, at 1 g. The mixture was continuously mixed on a vortex mixer at room temperature for thirty minutes. After extraction, the samples were centrifuged at 9000 x g for ten minutes at 4°C to obtain the supernatant and then filtered into vials using cellulose membranes. The extracts were stored at -20°C for further investigation. The high-performance liquid chromatography (HPLC) system was equipped with a refractive index detector (Shimadzu RID 20A VP, Kyoto, Japan), an in-line degasser, a pump, a controller, and a 20 µL injection volume automatic injector. Chromatographic separation was performed using a reverse-phase Ultrasphere Coregel-87 C analytical column (300 mm × 7.8 mm i.d., 5 µm, Transgenomic) at a flow rate of 0.6 mL/min, heated to 70 °C, and with the mobile phase being ultrapure water. Data acquisition and processing were performed with Shimadzu Class VP chromatography management software (Kyoto, Japan).

Concentrations of individual sugars are reported as percentages of fresh weight (FW) determined using original standards.

Volatile compounds were extracted by solid-phase microextraction (SPME)

Volatile compounds obtained from bitter melon fruit juice were studied using three randomly selected fruits at each stage, both unripe and commercially ripe. For each case, 1 gram of homogenized seed tissue was placed in a headspace vial, and then 1 mL of CaCl₂ was added. Following a 30-minute 40 °C treatment, the volatile components were extracted using a solid-phase microextraction (SPME) fiber coated with CAR/PDMS/ DVB (gray fiber). Using the method detailed by Polat and colleagues (2022), the obtained aroma compounds were then analyzed and quantified using a Shimadzu GC-2010 Plus gas chromatography-mass spectrometry (GC/MS) system.).

Statistical Analysis

The experiment was conducted using a completely randomized block design with three replications in Türkiye. A total of four trees were selected, and eight fruits were harvested from each tree at the commercial maturity stage. The collected fruits were traditionally dried using conventional methods and subsequently subjected to biochemical analyses. Data were processed using the SPSS statistical package program (version 23.0; SPSS Inc., Chicago, IL, USA). All results were expressed as mean ± standard error (SE) and evaluated by one-way analysis of variance (ANOVA) following the procedure described by Steel et al. (1997).

RESULTS AND DISCUSSION

The DPPH assay is one of the most widely used methods for evaluating the antioxidant capacity of plant extracts. It is based on the reduction of the stable 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical by physiologically active compounds with antioxidant potential, including tocopherols, ascorbates, flavonoids, aromatic amines, Maillard-type browning products, and peptides. Upon accepting an electron or hydrogen atom from these compounds, the deep violet color of DPPH fades, and the degree of discoloration can be quantified spectrophotometrically. This change reflects the hydrogen-donating ability of the sample, which is a direct indicator of its radical scavenging activity (Re et al., 1991).

Among phytochemicals, phenolics and polyphenols have attracted significant attention because of their diverse physiological functions, including antioxidant, antimutagenic, and antitumor activities (Othman et al., 2007). Plant phenolics, abundant in fruits and vegetables, are recognized for their free radical scavenging abilities, which may have important health-promoting implications (Dziedzic & Hudson, 1983; Lopez-Velez et al., 2003; Li et al., 2006; Govindarajan et al., 2007; Imeh and Khokhar, 2002; Ross and Kasum, 2002). Within this group, anthocyanins represent a major class of flavonoids responsible for the cyanic coloration observed in many flowers, fruits, and leaves of angiosperms, with hues ranging from salmon pink to dark blue (Andersen et al., 2006). In recent years, interest in anthocyanins has increased considerably due to their potential role as nutritional supplements. Regular dietary intake of anthocyanins from fruits, vegetables, wines, jams, and preserves has been linked to a reduced risk of chronic diseases such as cancer, cardiovascular disorders, diabetes mellitus, hypertension, cataracts, viral infections, and Alzheimer's disease. Their strong antioxidant capacity underlies their classification as important nutraceuticals, with a potential preventive role in diseases associated with oxidative stress (Glade, 1997; Middleton et al., 2000).

Total phenolic content (TPC)

Total phenolic content (TPC) was determined using gallic acid as a standard, and the results were expressed as mg GAE/g fruit sample. The TPC value for bitter melon juice extract was **47.54 ± 0.51 mg GAE/g (Table 1; Figure 1)**. For fraction extracts, the TPC values ranged from **4.64 to 6.84, 6.03 to 8.94, 5.39 to 7.81, and 6.07 to 8.90 mg CAE/g**, respectively (Horax et al., 2010).

Previous studies have also reported considerable variation in phenolic content among different bitter melon tissues and extracts. Kubola and Siriamornpun (2008) reported TPC values of **474 ± 0.71 mg GAE/g** in leaves, **324 ± 1.63 mg GAE/g** in green fruits, **259 ± 1.20 mg GAE/g** in stems, and **224 ± 0.86 mg GAE/g** in ripe fruits, all expressed on a dry weight basis. Similarly, Wang et al. (2019) found TPC values ranging from **4.81 to 6.09 mg GAE/g dw**, while Dongmoon (2013) reported that bitter melon extract contained **49.42 ± 1.28 mg GAE/g**, confirming its high phenolic concentration.

The present results are in agreement with these findings, indicating that *M. charantia* fruits are rich sources of polyphenolic compounds. Such high phenolic content is closely associated with the antioxidant activity of bitter melon and supports its potential as a functional food (Kubola and Siriamornpun, 2008; Horax et al., 2010).

Antioxidant activity (DPPH Radical Scavenging Assay)

In the present study, the antioxidant capacity of bitter melon was evaluated using the DPPH radical scavenging assay, and the inhibition value was determined as 24.08% (Table 1; Figure 1). These results are comparable with the findings of Tan et al. (2013), who reported that the percentage of DPPH scavenging activity in bitter melon ranged from 15.18–22.19% in the hydrophilic fraction and 13.96–45.59% in the lipophilic fraction. Among different drying methods, freeze-dried bitter melon fruit extracts showed the highest radical scavenging activities (hydrophilic: 22.19%; lipophilic: 45.59%), followed by oven-dried samples at 50 °C (hydrophilic: 15.39%; lipophilic: 40.11%). Similarly, Horax et al. (2010) investigated four bitter melon varieties (India green, India white, China green, and China white) and found that the antioxidant activities of methanolic extracts ranged from 81.7–86.5% in the flesh, 78.8–88.4% in the inner tissue, and 78.5–85.4% in the seeds. In another study, Lee et al. (2017) reported that the DPPH and ABTS radical scavenging activities of bitter melon fruits were 61.57% (DPPH, dry material) and 46.99% (ABTS) at 5 days after fertilization, and these activities significantly increased to 222.86% and 122.87%, respectively, at 35 days after fertilization. Taken together, these results highlight the strong antioxidant potential of *M. charantia* fruits, although the extent of radical scavenging activity can vary considerably depending on the extraction solvent, fruit tissue, processing conditions, and maturity stage. The DPPH value obtained in the present study (24.08%) is in line with previously reported ranges and further supports the role of bitter melon as a promising source of natural antioxidants.

Total Anthocyanin Content

In the present study, the total anthocyanin content of bitter melon was determined as **21.18 ± 0.02 mg/L**, expressed as cyanidin-3-glucoside equivalents (Table 1; Figure 1). Güdr (2016) reported that the total anthocyanin contents of bitter melon extracts ranged from **24.48 to 31.04 mg/L** cyanidin-3-glucoside equivalents, which are slightly higher than the values observed in this study. Phytochemicals such as phenolics and flavonoids are well known for their health-promoting properties, and among these, anthocyanins represent one of the most biologically active groups of flavonoids. Their vivid colors and strong antioxidant properties not only contribute to the aesthetic and sensory qualities of plant-derived foods but also play a significant role in reducing oxidative stress and preventing chronic diseases (Kumar et al., 2013).

Table 1. Shows the results of bioactive compound of bitter melon

Total Antioxidant (DPPH)	24.08±3.10
Total Phenolic	47.54±0.51
Monomeric Anthocyanin	21.18±0.02

Figure 1. Contents Antioxidant Capacity (DPPH), Total Phenolic and Anthocyanin of bitter melon
Sugars and Organic Acids Composition

In this study, four sugars sucrose, xylose, glucose, and fructose were identified, with glucose and fructose being the predominant components (Table 2; Figure 2). Among them, glucose was the most abundant sugar (367.52 ± 12.32 mg/100 g), followed by fructose (229.43 ± 8.20 mg/100 g), sucrose (88.57 ± 2.28 mg/100 g), and xylose (53.38 ± 2.62 mg/100 g). The total sugar content was determined as 738.91 ± 9.04 mg/100 g.

Organic acids, which play a crucial role in flavor development and several physiological processes in fruits, were also quantified. The sugar–acid balance is considered a key factor in determining fruit taste characteristics. In the bitter melon samples, citric acid was identified as the dominant organic acid (55.78 ± 3.14 mg/100 g), followed by malic acid (20.34 ± 4.33 mg/100 g), and ascorbic acid (10.49 ± 6.15 mg/100 g). The total organic acid content was calculated as 308.06 ± 6.41 mg/100 g (Table 3; Figure 3).

For sugars: Previous studies by Kubola & Siriamornpun (2008) also reported that glucose and fructose are the main sugars in bitter melon. This finding supports the results obtained in the present study.

For organic acids: Perez et al. (2019) reported the detection of several organic acids in bitter melon, including succinic, malic, fumaric, and tartaric acids, some of which had not been previously identified in this species. Studies by Horax et al. (2010) and Tan et al. (2013) indicated that malic and citric acids are the predominant organic acids; however, the dominant acid may vary depending on ecological conditions. The higher succinic acid content observed in the current study may reflect the influence of the specific ecological conditions of Adana.

In study, glucose and fructose were found to be the predominant sugars, and succinic acid was identified as the major organic acid in bitter melon fruits grown under the ecological conditions of Adana. These findings are consistent with previous studies, such as Kubola and Siriamornpun (2008) and Horax et al. (2010), and indicate that the ecological conditions of Adana may influence these compositional characteristics. However, the concentrations measured in Adana-grown fruits are

relatively higher, possibly due to the warmer and sunnier Mediterranean climate, which promotes sugar accumulation.

Volatile Compounds of Bitter Melon Juice

Headspace Solid Phase Microextraction (HS-SPME) is a widely used technique for the identification and analysis of volatile essential oils and aroma compounds, provided that the target compounds are adequately distributed on the fiber (Toci et al., 2012). HS-SPME allows a rapid, solvent-free extraction of volatiles from the headspace above the sample onto a stationary phase coated on a fused silica fiber (Roberts et al., 2000). Gas chromatography (GC), often coupled with mass spectrometry (GC-MS), is a fundamental analytical technique for analyzing plant metabolites due to its efficiency, sensitivity, and versatility (Sgorbini et al., 2006). In the present study, volatile compounds in bitter melon juice were analyzed using the gray SPME method. The major classes of volatiles were identified as total aldehydes (4.43%), total alcohols (34.59%), total esters (48.18%), total ketones (7.27%), and total acids (5.53%) (Figure 4). A total of 31 individual components were detected, including 10 alcohols, 2 aldehydes, 12 esters, 4 acids, and 2 ketones (Table 4). Among the extraction methods tested, the gray SPME method proved most effective. Alcohols and esters were the predominant compounds in the volatile profile. The most abundant alcohols were **ethanol (11.80%)**, **2-phenylethanol (benzeneethanol) (9.01%)**, and **(Z)-3-hexen-1-ol (4.39%)**. Among esters, **ethyl acetate (23.91%)**, **2-phenylethyl acetate (5.51%)**, and **ethyl 9-hexadecenoate (5.93%)** were dominant. For ketones, **2,3-dihydro-3,5-dihydroxy-6-methyl-4H-pyran-4-one (5.36%)** was the main compound. The most abundant acids were **pentadecanoic acid (2.45%)** and **2-oxopentanedioic acid (1.08%)** (Table 4). These results highlight that alcohols and esters are the primary contributors to the aroma profile of bitter melon juice, which may be significant for both sensory and functional properties. GC-MS analysis confirmed that esters and alcohols dominate the VOC profile, consistent with previous reports (Choudhury et al., 2012). The most abundant VOCs included **ethyl acetate**, **ethanol**, **2-phenylethanol**, and **5-(hydroxymethyl)-2-furfural**, which contribute substantially to the characteristic aroma of bitter melon.

Several studies have examined VOCs in different parts of *M. charantia*. Ferreira Almeida et al. (2025) reported 18 and 21 compounds in mature fruits, depending on the extraction method, with **benzaldehyde**, **linalool**, and **β -cyclocitral** consistently identified, and **linalool** as the major compound. For the flower, Fernando and Grün (2001) found **linalool (5%)**, **2-aminobenzaldehyde (27%)**, **1H-indole (33%)**, and **methyl anthranilate (32%)**, together comprising over 95% of the headspace volatiles. Moronkola et al. (2009) identified 63 compounds (88.8% of the total oil) in the

essential oil, with **(Z)-3-hexenol (34.7%)**, **(E)-2-hexenol (10.1%)**, **phytol (8.3%)**, and **linalool (5.8%)** as the major constituents.

Collectively, these studies illustrate the diversity of volatile compounds in bitter melon fruits, flowers, and oils, emphasizing the influence of plant part, extraction method, and environmental conditions on VOC profiles. Notably, the ecological conditions of Adana not only support bioactive compound synthesis but also promote a rich and complex aromatic composition. The relatively higher ester content compared to some Asian studies may be linked to environmental factors, such as heat stress, which can affect metabolic pathways involved in ester biosynthesis.

CONCLUSIONS

This study comprehensively evaluated the biochemical composition and volatile organic compound (VOC) profile of bitter melon (*M. charantia* L.) cultivated under the ecological conditions of Adana, Türkiye. The fruits were rich in bioactive compounds, with glucose and fructose as the predominant sugars and succinic acid as the main organic acid. Total phenolic content, antioxidant activity (DPPH), and total anthocyanins were also notable, highlighting the fruit's functional and nutraceutical potential. VOC analysis revealed that alcohols and esters were the major contributors to the aroma profile, with Acetic acid ethyl ester, ethanol, and Benzeneethanol, as the most abundant compounds. Comparative evaluation with previous studies showed that VOC composition and abundance vary depending on plant part, extraction method, and environmental factors. The relatively higher ester content in Adana-grown bitter melon may be linked to high temperatures and prolonged sunlight, which can influence ester biosynthesis pathways.

These findings confirm the multifunctional nature of bitter melon. Its traditional ethnomedicinal uses, including antidiabetic, anti-inflammatory, and antimicrobial applications, are strongly supported by its bioactive composition (Ray et al., 2010; Alam et al., 2016). Moreover, its climbing growth habit, ornamental yellow flowers, and lobed foliage highlight its dual role as both a functional food and an ornamental plant. Adana-grown bitter melon exhibits a rich biochemical composition, moderate antioxidant potential, and a complex volatile profile, making it a promising candidate for functional food applications, bioactive compound extraction, and natural aroma production. Simultaneously, its ornamental characteristics allow its use in garden and urban

landscapes. Future research should aim to optimize cultivation practices under Mediterranean conditions to enhance bioactive compound production and explore breeding programs that combine nutritional, functional, and ornamental traits.

ABSTRACT

The aim of this work is to conduct a study on a binary polymer blend in order to combine the characteristics of two polymers, namely sodium alginate and hydroxypropyl methylcellulose. This combination will result in the formation of a viscous blend. Several binary mixtures were prepared at different ratios, for which we studied the effect of pH and ionic strength variation. These mixtures will undergo physico-chemical and rheological characterisation in order to evaluate the effect of pH and ionic strength on the properties of the different polymer mixtures considered. The results revealed that the highest absorbance is observed for sodium thiosulphate, probably due to the dissolution of Na₂ S₂ O₃ in water. The study of viscoelastic behaviour in oscillatory modulus revealed gelation, which was recorded for pH values of 2 and 2.5, where phase separation was observed. The concentration of salt added had an effect on the macroscopic and microscopic appearance of the different polymer ratios.

Keywords: Alginate-Na, HPMC, interaction, rheology, ionic strength, pH .

INTRODUCTION

Molecular interactions are ubiquitous and occur in all states of matter. In the field of polymer physical chemistry, much research focuses on the study of so-called weak molecular interactions in soft matter. These non-covalent interactions, which have low energy compared to covalent bonds, are mostly reversible. [1]

Mixtures of polymers in aqueous solution generally lead to three types of phenomena: total miscibility, segregative phase separation when the interaction between the solvent and one of the polymers is strong, or associative phase separation when the interaction between the two polymers is strong. The latter phenomenon is called complex coacervation [2, 3].

This coacervation depends on environmental conditions such as pH, ionic strength, temperature, and polymer concentration [4–10] ...

To this end, two polysaccharides were selected for development: sodium alginate (Alg-Na) and hydroxypropyl methylcellulose (HPMC).

HPMC is a synthetic polymer derived from cellulose, widely used for its gelling, adhesive and drug release control properties. Sodium alginate, on the other hand, is a natural polymer extracted from brown algae, known for its ability to form gels in the presence of calcium [11].

The interactions between HPMC and sodium alginate are mainly due to mechanisms such as electrostatic interactions, hydrogen bonds and hydrophobic interactions.

The aim of our study is to conduct a study on a binary polymer blend in order to combine the interactions between sodium alginate and HPMC and to see the effect of pH variation and different ionic strengths (sodium thiosulphate, sodium chloride and potassium chloride).

To this end, a physico-chemical and rheological characterisation was carried out in order to evaluate the effect of pH and ionic strength on the properties of the different polymer blends studied.

MATERIALS AND METHODS

Medium-grade sodium alginate was used in this study by Sigma Aldrich, HPMC was supplied by Novapharm and acts as an emulsifier. Sodium thiosulphate is an inorganic sodium salt with the formula $\text{Na}_2\text{S}_2\text{O}_3$ composed of a mixture of sodium and thiosulphate ions. Sodium chloride is an ionic chemical compound with the formula NaCl . Potassium chloride is a mineral chemical compound with the formula KCl . In our study, these three salts are used as ionic forces.

RESULTS AND DISCUSSIONS

Observations and interpretation of macroscopic and microscopic results

For the alginate solution alone, gel formation was observed at $\text{pH}=3.5$ with no precipitate formation, as demonstrated by microscopic examination, which revealed the formation of transparent aggregates. For the other ratios 1/2, 2/1 and 1.5/1.5, visual examination of the test tubes shows cloudiness from pH 3.5 onwards, with an opalescent appearance, confirming the interaction between the polymers, but of a weak nature since no precipitate is observed.

The effect of ionic strength on Alg-Na/HPMC ratios

We represent the range of Alginate/HPMC mixture samples with the effect of salt:

1. Sodium thiosulphate (0.1M):

For the alginate solution alone, we observe the formation of a white precipitate at the bottom of the tubes starting at pH 3, which becomes increasingly visible as the pH decreases.

For the other ratios 1/2, 2/1 and 1.5/1.5, we observe that phase separation is even more visible at acidic pH values, namely pH 3.5, 3, 2.5) with the formation of a white precipitate and a transparent supernatant. Under the microscope, we see more or less dense aggregates resulting from the interaction of the two polymers in the presence of salt.

This separation can be explained by the effect of salt in accelerating the neutralisation of the ionic charges present in the polymers. For example, for a 1/2 ratio, a white precipitate appears at a pH of 3, confirmed by microscopy, where dense aggregates are observed. This phenomenon can be explained by the saturation of anionic and cationic sites by the Na^+ ions in the thiosulphate, which is justified by the competition between the ions and the micromolecules. In reality, this means that at high ion concentrations in the solution, the charges carried by the biopolymers are reduced by interactions with these ions, which then neutralise the biopolymers, causing them to precipitate.

KCl and NaCl appear to have the same effect on alginate solutions alone and polymer blends, as precipitation occurs with phase separation at acidic pH (from 3 onwards) with aggregates visible under an optical microscope. This confirms the role of salt (K^+ and Na^+ ions) in neutralising charges by saturating the anionic sites of biopolymers, which contributes to changes in polymer solubility and precipitation.

Variation in the absorbance of Alg-Na/HPMC binary mixtures at 600 nm as a function of pH and ratio

The absorbance variation results at 600 nm obtained for the Alg-Na/HPMC mixture at a total polymer concentration of 3% show that for Alg-Na/HPMC ratios between 1/2, 2/1 and 1.5/1.5, all curves show maximum absorbance at pH 2.5 to 2. We also estimate that for a given pH value, a maximum variation in the absorbance of the mixture is linked to the formation of a maximum number of particles and therefore maximum interaction between the two macromolecules [80].

Figure . 1: Variation in absorbance as a function of pH for different Alg-Na/HPMC ratios without ionic strength

Figure 2: Variation in absorbance as a function of pH for the Alg-Na/HPMC 3/0 ratio (KCl, $\text{Na}_2\text{S}_2\text{O}_3$ 0.1M)

Figure 3: Variation in absorbance as function of pH for the ratio Alg-Na/HPMC 0/3 (KCl, Na₂S₂O₃) 0.1M

Figure 4: Variation de l'absorbance as function of pH for the ratio Alg-Na/HPMC 1/2 (KCl, Na₂S₂O₃, NaCl) 0.1M

Figure 5: Variation in absorbance as function of pH for the ratio Alg-Na/HPMC 2/1 (KCl, Na₂S₂O₃) 0.1M

Figure 6: Variation in absorbance as function of pH for the ratio Alg-Na/HPMC 1.5/1.5 (KCl, Na₂S₂O₃) 0.1M

Figures (1-6) representing the variation in absorbance for ratios (3/0, 0/3, 1/2, 2/1, 1.5/1.5) show maximum absorbance at around pH 2 and 2.5 in the presence of ionic strengths ($\text{Na}_2\text{S}_2\text{O}_3$, KCl, and NaCl) 0.1M. Under these conditions, the electrostatic interactions between Alg-Na and HPMC cause a phase separation known as segregation. These results are consistent with the macroscopic findings. The highest absorbance is observed at the sodium thiosulphate level, which is probably due to its dissolution in water.

Rheological characterization of binary Alg-Na/HPMC mixtures at different ratios without ionic forces

The flow curve of the graph representing the five ratios is shown in (Figure 7).

These solutions exhibit two types of behaviour: the first is Newtonian behaviour at low shear rates and rheofluidising behaviour at intermediate shear rates, reflecting the structural behaviour of the two biopolymers. At low shear rates, the physical bonds resist flow. As the shear rate increases, shear causes the physical bonds between the macromolecules to break, resulting in partial destructuring depending on the intensity of the shear, which manifests itself in their dispersion. When the shear is very strong, the macromolecules are completely dispersed and oriented along the flow, and their resistance becomes constant, as does the viscosity. The same type of behaviour was found by Belhadji et al. [81] in the case of sodium alginate solutions with xanthan.

Figure.7 Variation in viscosity as a function of shear rate at different ratios

Viscoelastic behavior

In order to analyze and compare the results obtained, we presented the conservation modulus curves for the different ratios and pH values (Figures 8-10) without ionic forces

Figure . 8: Variation of the storage modulus G' as a function of deformation for R1/2 with an ionic strength of $\text{Na}_2\text{S}_2\text{O}_3$ 0.1M

Figure . 9: Variation of the storage modulus G' as a function of deformation for R1/2 with an ionic strength of 0.1M KCl

Figure . 10: Variation of the storage modulus G' as a function of deformation for R1/2 with an ionic force NaCl

For the 1/2 ratio for the three salts ($\text{Na}_2\text{S}_2\text{O}_3$, NaCl, KCl), the maximum G' values are recorded for pH values of 2 and 2.5, where phase separation is observed. Based on the macroscopic appearance, this is an associative phase separation. [1] These results are consistent with the turbidity results, for which we recorded maximum absorbance values at the same pH values highlighted above.

CONCLUSIONS

The objective of this work is to study the physicochemical and rheological characteristics of a binary polymer blend in order to observe their interactions. Several binary blends were prepared at different ratios, for which we studied the effect of pH and ionic strength variation.

To do this, we combined two polymers: sodium alginate and HPMC.

At the end of this study, we obtained the following results:

- For the alginate solution alone, gel formation was observed at pH=3.5 with no precipitate formation, as demonstrated by microscopic examination, which revealed the formation of transparent aggregates.
- For the other ratios 1/2, 2/1 and 1.5/1.5, visual examination of the test tubes showed cloudiness from pH 3.5 onwards, with an opalescent appearance, confirming the interaction between the polymers, but of a weak nature since no precipitate was observed.

□□ The concentration of salt added has an effect on the macroscopic and microscopic appearance of the different polymer ratios.

□□ For the other ratios 1/2, 2/1 and 1.5/1.5, we observe that phase separation is even more visible at acidic pH values (pH 3.5, 3, 2.5) with the formation of a white precipitate and a transparent supernatant. Under the microscope, we can see more or less dense aggregates resulting from the interaction of the two polymers in the presence of salt.

KCl and NaCl appear to have the same effect on alginate solutions alone and polymer blends, as precipitation occurs with phase separation at acidic pH (from 3 onwards) with aggregates visible under an optical microscope.

□□ The highest absorbance is observed for sodium thiosulphate, probably due to its dissolution in water.

The 1/2 ratio for the three salts (, the maximum G' values are recorded for pH 2 and 2.5, where phase separation is observed (Tables III.2, III.3 and III.4). Based on the macroscopic appearance, we have associative phase separation.

ABSTRACT

Soil conditioners are crucial for improving soil quality and sustaining cereal production in the face of mounting environmental and agronomic challenges. This study examines the various types, mechanisms and effects of organic, inorganic and synthetic soil conditioners on soil physical properties, water retention, nutrient availability, microbial activity and soil structure as a whole. Through a comprehensive review of recent research and experimental evidence, we evaluate the influence of conditioners on short- and long-term cereal crop productivity, considering factors such as improved soil fertility, reduced compaction, and mitigation of the effects of salinity and erosion. Organic amendments, such as compost, manure and humic acids, improve aggregation and biological activity, whereas inorganic agents, such as gypsum and lime, enhance ion exchange and pH balance. Synthetic polymers contribute to erosion control and moisture conservation. Furthermore, integrating conditioners with slow-release fertilisers and sustainable management practices has demonstrated synergistic effects on yield improvement and soil health. Our findings emphasise the importance of judicious application of soil conditioners for achieving resilient and sustainable cereal production systems, particularly in degraded or marginal soils.

Keywords: Soil Conditioners, Cereal Crops, Sustainable Agriculture, Soil Health

INTRODUCTION

Cereal crops such as wheat, maize, barley, and rice are the cornerstone of global food security, yet their production is increasingly threatened by soil degradation, nutrient depletion, and climate variability. Sustainable intensification of cereal systems requires strategies that improve soil physical, chemical, and biological functions. Soil conditioners including organic amendments, inorganic inputs, and synthetic products are central to these strategies because they directly influence soil structure, water relations, and nutrient cycling while also contributing to long term soil health (Jarecki & Lal, 2003).

One of the most pressing challenges is the decline of soil organic carbon (SOC) due to intensive cultivation and conventional tillage, which has reduced soil fertility and resilience across many agroecosystems. Restoring SOC stocks through organic amendments, cover crops, and reduced tillage has been shown to improve aggregation, enhance microbial activity, and reduce erosion, all of which are critical for sustaining cereal productivity (Morya et al., 2023). In addition, soil conditioners act as vehicles for carbon sequestration, offering mitigation potential against greenhouse gas emissions while improving nutrient retention in cropping systems (Zhang et al., 2024).

Beyond their role in carbon management, conditioners influence the efficiency of nutrient use. Integrating conditioners with precision nutrient application technologies can optimize fertilizer delivery, minimize losses, and improve nutrient uptake in cereals (Raza et al., 2023). This synergy between conditioners and nutrient management is particularly important under conditions of high variability in soil fertility and water availability, as it promotes yield stability while reducing environmental externalities.

The adoption of conditioners is also aligned with climate smart agriculture principles, as they contribute to soil resilience under stresses such as drought and salinity. For instance, organic inputs such as compost and biochar improve soil water holding capacity, while gypsum and lime alleviate sodicity and acidity constraints (Morya et al., 2023; Jarecki & Lal, 2003). Together, these interventions highlight the dual role of soil conditioners in enhancing immediate crop performance and securing long term ecological sustainability.

This paper explores the classification, mechanisms, and impacts of soil conditioners in cereal production systems. By synthesizing experimental evidence and recent reviews, it provides a framework for understanding how conditioners contribute to improved soil quality, enhanced nutrient use, and resilient crop yields under diverse environmental and management contexts.

SOIL CONDITIONERS CLASSIFICATION

Soil conditioners encompass a wide spectrum of materials deliberately applied to soils to improve their physical, chemical, and biological properties. In the context of cereal production, these conditioners are typically grouped into organic, inorganic, and synthetic amendments. Each category provides unique advantages and limitations, and their comparative effectiveness often depends on soil type, climate, and cropping system.

Organic conditioners such as compost, farmyard manure, green manure, crop residues, and biochar are indispensable for building soil organic matter (SOM). Their value lies not only in supplying nutrients but also in enhancing soil structure, microbial diversity, and water dynamics. Paustian (2000) emphasized that adoption of practices like residue retention, cover cropping, and reduced disturbance is crucial for maximizing organic matter inputs and thereby stabilizing carbon in soil systems.

Ingram and Fernandez (2001) also underlined the ecological dimension of organic conditioners, stressing their role in sustaining carbon inputs over multiple rotations, which supports aggregate stability and minimizes nutrient leaching. Application of biochar and compost has shown promising results in increasing soil cation exchange capacity (CEC), thereby enhancing nutrient retention and reducing fertilizer losses. Over time, these organic materials build a more resilient soil system, capable of buffering cereals against stress conditions such as drought or nutrient fluctuations. However, a limitation of organic conditioners is that their effects may take several years to manifest fully, as stabilization of carbon and improvement in aggregation are gradual processes.

Inorganic amendments such as gypsum, lime, and phosphogypsum are widely recognized for their capacity to correct chemical imbalances. Gypsum application reduces sodium induced dispersion,

improves infiltration, and restores root growth in sodic soils. Lime, conversely, neutralizes soil acidity, reduces aluminum toxicity, and enhances phosphorus availability. West and Post (2002) demonstrated that combining mineral amendments with conservation tillage significantly improved soil carbon sequestration rates, indicating their dual role in both fertility restoration and carbon management.

A major strength of inorganic conditioners is their relatively rapid effect compared to organic amendments. For example, liming acidic soils often results in visible yield responses within the first season. Nevertheless, repeated application may be required to maintain soil chemical balance, and over application can lead to secondary issues such as micronutrient deficiencies. Thus, their use requires careful calibration based on soil testing and site specific conditions.

Synthetic conditioners, including hydrogels, polyacrylamides, and other water retaining polymers, represent a more recent technological innovation. They are particularly valuable in regions where water scarcity and erosion are limiting factors for cereal production. Six et al. (1998) illustrated that aggregate stability plays a central role in determining the persistence of organic matter in soils, and synthetic conditioners can directly enhance this stability by reducing crusting and surface sealing.

Hydrogels, for instance, can store many times their weight in water and release it gradually to plant roots, significantly improving water use efficiency under dry conditions. Polyacrylamides, when applied to the soil surface, have been shown to reduce runoff and sediment loss, contributing to both water conservation and soil protection. Despite these advantages, concerns remain about the cost of application and the long term ecological impacts of synthetic materials, such as their persistence in soil and potential interactions with soil biota.

The effectiveness of soil conditioners increases when they are used in a complementary manner. Doran and Smith (1987) highlighted that conservation systems integrating crop residues with minimal soil disturbance not only enhance microbial biomass but also improve nutrient cycling efficiency. Wairiu and Lal (2003) further demonstrated that the integration of conditioners with crop rotation and reduced tillage can restore carbon pools and maintain soil fertility on sloping lands, where erosion pressure is high.

The integrative use of conditioners highlights a critical point: while organic amendments build long term soil resilience, inorganic materials provide immediate corrections for chemical imbalances, and synthetic conditioners deliver short term technological solutions to address acute stress factors. A holistic approach that combines these inputs ensures sustained cereal productivity while simultaneously contributing to soil carbon sequestration and ecological sustainability

Table 1. Soil conditioners and their primary functions in cereal production

Conditioner Type	Examples	Main Effects	Impact on Cereals
Organic	Compost, manure, biochar	Improves SOM, aggregation, microbial biomass	Enhances yield stability, nutrient uptake
Inorganic	Lime, gypsum, phosphogypsum	Corrects pH, reduces sodicity, improves CEC	Boosts root growth, improves P availability
Synthetic	Hydrogels, polyacrylamides	Increases water retention, reduces erosion	Improves drought tolerance, water-use efficiency

SOIL PROPERTIES EFFECTS

The influence of soil conditioners on soil properties is multifaceted, impacting the physical, chemical, and hydrological characteristics of soils. These changes are central to ensuring that cereal crops thrive under both optimal and stress prone conditions. By modifying soil texture, aggregation,

nutrient pools, and erosion dynamics, conditioners create a more balanced and resilient environment for sustainable cereal production.

One of the primary contributions of soil conditioners is the improvement of soil structure through aggregation and stabilization. Tisdall and Oades (1982) reported that the addition of organic residues enhances the formation of water stable aggregates, which protect soil organic matter and reduce susceptibility to erosion. These stable aggregates improve porosity, allowing better gas exchange and root penetration. The flow of energy, organic matter transformation, and nutrient cycling within the soil ecosystem occur through interconnected processes (Figure 1).

Figure 1. Schematic representation of major soil processes influencing nutrient cycling and organic matter dynamics. The diagram illustrates pathways of decomposition, mineralization, weathering, infiltration, and leaching, which together determine nutrient availability, soil formation, and plant uptake in cereal-based systems.

Bulk density is another parameter directly influenced by conditioners. Cameron et al. (1981) demonstrated that continuous cultivation without organic inputs leads to higher bulk density and reduced pore space, restricting water infiltration and root development. The application of conditioners reduces bulk density and increases micropore volume, which is particularly advantageous for cereals like wheat and maize, where root proliferation in the upper soil layers is critical for water and nutrient uptake. Improved porosity also enhances infiltration rates, reducing surface runoff and making water more available for plant use.

Conditioners also exert a strong influence on soil chemistry, particularly nutrient dynamics and pH balance. Dalal and Mayer (1986) highlighted that intensive cultivation without amendments depletes total and mineralizable nitrogen pools, leading to nutrient imbalances and reduced soil fertility. Incorporating conditioners such as manures, composts, or lime helps restore nitrogen fractions and maintains a steady supply of nutrients for cereals.

pH regulation is another important function. Mann (1986) demonstrated that acid soils lose significant amounts of soil carbon after cultivation, a process that can be mitigated through liming. Lime reduces soil acidity, enhances phosphorus availability, and alleviates aluminum toxicity, all of which are essential for robust cereal growth. Gypsum also plays a role by supplying calcium and

improving cation exchange capacity (CEC), which counteracts sodicity and improves root zone conditions. These chemical corrections ensure that essential nutrients remain available and accessible throughout the growing season.

Soil conditioners also affect the hydrological properties of soils by enhancing water retention and infiltration. Improved aggregation and porosity facilitate deeper water movement into the profile, while organic conditioners such as compost and biochar increase the soil's capacity to store moisture. For cereals grown in semi arid environments, this enhanced water holding capacity is critical for bridging dry spells and ensuring yield stability. Tisdall and Oades (1982) further emphasized that organic matter plays a dual role by not only binding particles into aggregates but also acting as a sponge to retain soil water, improving drought resilience.

The long term application of conditioners contributes to the stability of soil organic carbon (SOC) pools and nutrient cycling. Follett et al. (1987) found that conservation tillage combined with residue retention decreases the loss of SOC associated with eroded sediments by nearly half compared to conventional tillage. This demonstrates that conditioners are essential not only for improving soil fertility but also for mitigating soil erosion and carbon loss. Over time, these effects create a positive soil carbon balance, transforming soils from carbon sources to carbon sinks.

The preservation of SOC is particularly important for cereals, as it directly correlates with yield stability and soil resilience. By minimizing erosion and leaching, conditioners maintain critical topsoil layers rich in nutrients and organic matter. This ensures that cereal cropping systems remain productive while simultaneously supporting global efforts to mitigate greenhouse gas emissions.

SOIL BIOLOGICAL ACTIVITY AND MICROBIAL DYNAMICS

Soil conditioners not only modify the physical and chemical environment of soils but also exert strong control over the biological functioning of the soil ecosystem. Microorganisms—bacteria, fungi, and actinomycetes—respond sensitively to changes in organic matter, pH, nutrient levels, and moisture. Through these responses, soil conditioners shape nutrient availability, soil resilience, and cereal crop productivity.

Organic amendments such as compost, manure, crop residues, and biochar provide energy rich substrates that stimulate microbial growth. Jenkinson and Ladd (1981) demonstrated that the addition of fresh organic matter significantly increases microbial biomass carbon, which acts as a labile reservoir of nutrients. Swift (1987) further explained that the quality of organic residues—for example, residues with low lignin and high nitrogen content—accelerates decomposition and promotes microbial turnover, while resistant materials such as straw with high lignin content decompose more slowly, stabilizing soil carbon. This balance between easily decomposable and recalcitrant fractions underpins both immediate nutrient release and long term carbon sequestration.

Inorganic conditioners, particularly lime and gypsum, indirectly influence microbial communities by altering soil chemical conditions. Haynes and Naidu (1998) reported that liming acidic soils reduces aluminum toxicity and enhances base saturation, creating an environment where microbial diversity can flourish. Gypsum, by improving soil structure and reducing sodicity, provides better aeration and root growth conditions, which in turn stimulate rhizosphere microbial activity. These changes are particularly beneficial in cereal systems where root–microbe interactions strongly affect nutrient uptake.

Soil conditioners influence microbial processes at a biochemical level. Balota et al. (1998) observed that microbial biomass and enzyme activities—such as dehydrogenase, phosphatase, and urease—are consistently higher in soils with organic inputs compared to conventional systems. These enzymes are crucial for breaking down organic compounds and releasing nutrients like nitrogen,

phosphorus, and sulfur in forms readily available to cereals. Increased enzymatic activity not only accelerates nutrient cycling but also enhances the efficiency of fertilizer use, thereby reducing nutrient losses to the environment.

Microbial activity contributes directly to soil aggregation and stabilization of soil organic matter. Powlson et al. (1987) showed that soils receiving straw or compost amendments maintained higher microbial biomass, which was closely linked to improved aggregate stability. Greenland and Szabolcs (1994) highlighted that resilient soils are characterized by active microbial populations that produce polysaccharides and glomalin like substances, binding soil particles together and protecting carbon within aggregates. In this way, microbial activity creates a feedback loop where conditioners stimulate microbes, and microbes in turn stabilize soil structure and protect organic matter.

Enhanced microbial diversity promoted by conditioners also contributes to disease suppression. Competitive exclusion, production of antimicrobial compounds, and stimulation of beneficial organisms such as mycorrhizal fungi help protect cereal roots from soil borne pathogens. While not a direct function of conditioners themselves, the enrichment of microbial communities indirectly fosters a healthier rhizosphere, reducing the need for chemical disease control.

Over longer time scales, conditioners build microbial resilience. Powlson et al. (1987) demonstrated that repeated organic inputs maintain microbial populations even under intensive cereal cropping, preventing declines in soil fertility. Greenland and Szabolcs (1994) emphasized that this resilience is fundamental to sustainable land use, as biologically active soils are more capable of withstanding climatic and management stresses. By maintaining microbial driven carbon and nutrient cycles, conditioners thus provide cereals with a stable supply of essential resources across years and crop rotations.

SOIL FERTILITY, STRESS TOLERANCE AND YIELD RESPONSES IN CEREALS

Soil conditioners directly influence nutrient uptake, stress tolerance, and yield stability in cereal crops. Their role extends beyond short term fertility enhancement, as they improve the soil's ability to supply essential nutrients under both favorable and stress conditions. Soil conditioners increase the efficiency of nutrient use in cereal systems by improving soil structure and nutrient availability. Blevins et al. (1983) reported that no tillage systems combined with organic amendments enhanced nitrogen use efficiency in maize by reducing leaching losses. Similarly, Thomas et al. (1996) showed that the incorporation of crop residues improved phosphorus availability in acidic soils, directly supporting cereal growth. These findings underline the role of conditioners in ensuring sustained nutrient supply throughout critical growth stages.

Conditioners contribute to resilience against abiotic stresses such as drought and salinity. Unger and McCalla (1980) demonstrated that residue management increases soil water storage and reduces evaporation, thus improving drought tolerance in wheat and sorghum systems. In sodic soils, the application of gypsum improves soil structure and root growth, which in turn enhances water and nutrient uptake. Additionally, Salinas Garcia et al. (1997) observed that long term organic amendments increased soil organic carbon and aggregate stability, providing cereals with greater buffering capacity against both drought and salinity stress.

The integration of conditioners into cereal production systems has consistently improved yields. Power et al. (1986) reported that manure application increased maize grain yield by improving nitrogen availability and soil moisture retention. Similarly, long term trials highlighted by Rasmussen and Collins (1991) demonstrated that soils with continuous organic inputs maintained higher yields under intensive cereal cropping compared to conventionally managed soils. These responses reflect both immediate improvements in soil fertility and the cumulative benefits of enhanced soil structure and biological activity.

Conditioners also play a crucial role in sustaining yields across multiple seasons. By improving nutrient use efficiency and stabilizing soil carbon pools, they reduce the dependence on high fertilizer inputs. Over time, these practices enhance soil fertility and resilience, allowing cereals to maintain productivity even under fluctuating climatic conditions. The cumulative evidence suggests that conditioners should not be viewed solely as yield boosting inputs but as integral components of sustainable soil management systems that balance productivity with long term ecological stability.

Table 2. Reported effects of soil conditioners on cereal crop performance

Parameter	Reported Effect	Example Reference
Nitrogen use efficiency	+15–25% with organic residues	Blevins et al. (1983)
Soil organic carbon	Increased by 0.2–0.4 Mg ha ⁻¹ yr ⁻¹	West & Post (2002)
Grain yield	+10–30% with manure + N fertilizer	Power et al. (1986)
Water holding capacity	Increased by 10–20% with biochar	Tisdall & Oades (1982)
Microbial biomass	20–40% higher in conservation systems	Balota et al. (1998)

INTEGRATION WITH FERTILIZER MANAGEMENT

The integration of soil conditioners with fertilizer management has been shown to significantly enhance nutrient use efficiency, soil fertility, and cereal productivity. Conditioners improve the physical and chemical environment of soils, thereby amplifying the effectiveness of both organic and inorganic fertilizers. When combined, these inputs create synergies that improve nutrient retention, minimize losses, and sustain soil health over the long term. The joint application of organic conditioners and inorganic fertilizers enhances nutrient cycling and soil fertility. Stevenson (1994) highlighted that organic matter improves cation exchange capacity (CEC), allowing mineral fertilizers such as ammonium and potassium to be retained in the root zone for longer periods. This interaction reduces leaching losses and provides cereals with a more sustained nutrient supply. Similarly, Doran et al. (1990) found that combining manure with nitrogen fertilizers improved soil microbial activity, which accelerated nutrient mineralization and increased crop yields. Conditioners can also enhance the performance of controlled release and slow-release fertilizers. Cooke and Hislop (1993) demonstrated that the use of soil conditioners alongside coated nitrogen fertilizers reduced volatilization losses and improved nitrogen uptake efficiency. This is particularly relevant in cereal systems where high nitrogen demand coincides with stages of rapid growth. By regulating nutrient release, conditioners ensure that fertilizers align more closely with plant requirements. Phosphate-solubilizing microorganisms (PSMs) enhance phosphorus availability to plants by converting organic and inorganic phosphorus compounds into bioavailable forms through enzymatic activities (Figure 2).

Figure 2. Role of phosphate-solubilizing microorganisms (PSMs) and root-microbe interactions in enhancing phosphorus availability and nutrient cycling in cereal-based systems.

The integration of conditioners with biofertilizers, such as nitrogen fixing bacteria and phosphate solubilizing microbes, creates additional synergies. Giller et al. (1997) reported that organic amendments provide energy substrates that support the establishment of microbial inoculants in soils. As a result, cereals benefit not only from enhanced microbial nitrogen fixation and phosphorus solubilization but also from improved soil structure and water relations.

The role of conditioners is increasingly important in the context of precision nutrient management. By improving soil heterogeneity and buffering capacity, conditioners allow variable rate fertilizer applications to be more effective. Cassman et al. (2002) emphasized that nutrient use efficiency in cereals can be maximized only when soil physical constraints are addressed simultaneously with fertilizer management, underscoring the value of conditioners as complementary inputs.

Long term trials have consistently shown that conditioner-fertilizer combinations lead to more resilient soils. Sanchez (1999) demonstrated that integrated fertility management systems, combining organic and inorganic inputs, improved yields while maintaining soil fertility under continuous cropping. These findings suggest that conditioners should be considered as essential components of integrated nutrient management strategies for sustaining cereal production under both intensive and resource limited farming systems.

CONCLUSION

Soil conditioners are indispensable tools for sustaining and improving cereal production systems worldwide. Their benefits extend well beyond short term soil amendments, as they enhance the physical structure of soils by improving aggregation, porosity, and water retention; correct chemical imbalances by adjusting pH, nutrient availability, and cation exchange capacity; and stimulate biological processes by increasing microbial biomass, enzymatic activity, and nutrient cycling. These combined effects provide cereals such as wheat, maize, barley, and rice with healthier root environments, more efficient nutrient uptake, and greater resilience under stress conditions.

The classification of conditioners into organic, inorganic, and synthetic groups highlights their complementary contributions. Organic amendments (e.g., compost, manure, biochar) support long term soil fertility and carbon sequestration, which directly benefits cereal yield stability. Inorganic inputs (e.g., gypsum, lime) resolve critical soil constraints that often limit cereal root development and nutrient acquisition. Synthetic conditioners provide targeted technological solutions for moisture conservation and erosion control, which are particularly relevant in cereal production areas prone to drought and soil degradation.

Integration of conditioners with fertilizer management further strengthens cereal productivity. When combined with mineral fertilizers, conditioners reduce nutrient losses, improve nitrogen and phosphorus use efficiency, and sustain yields across seasons. Their synergy with biofertilizers supports beneficial microbial populations in the rhizosphere, further enhancing nutrient cycling and stress tolerance. Long term trials confirm that these integrated systems maintain soil fertility while ensuring consistent grain yields under intensive cereal cropping.

From a broader perspective, soil conditioners contribute directly to the goals of climate smart agriculture, linking productivity with environmental stewardship. By sequestering soil carbon, enhancing nutrient use efficiency, and improving tolerance to drought and salinity, they provide cereal systems with the resilience needed to meet future food security challenges.

In conclusion, the judicious use and integration of soil conditioners are not optional but essential for the sustainable intensification of cereal production. Their role in maintaining soil health, supporting high yields, and buffering cereals against environmental stress makes them a cornerstone of future agricultural strategies worldwide.

ABSTRACT

This study indicates the simulation analysis of a solar powered solid adsorption machine using activated carbon AC35/methanol pair. For this purpose, a mathematical model based on a transient model of heat and mass transfer equations of the solar reactor (adsorber) has been developed. This model based on the hypothesis of homogeneity of pressure and non-homogeneity of temperature distribution inside the adsorber. The adsorbed methanol mass is given by the equation of DUBININ-ASTAKHOV to describe the phenomenon of adsorption. The discretization equations system is carried out using the method of finite differences with a fully implicit scheme and the resolution of the discretized system is carried out using the iterative method. This study enables us to calculate the profile of temperature, pressure adsorbed mass inside the adsorber according to time and during cloudy day, in order to study the effect of the adsorber dimensioning on the performance of the machine.

Key words: Adsorption, Solar refrigeration, Heat and mass transfer, Activated carbon - methanol.

INTRODUCTION

Ecological problems and energy crisis in a globalized world have motivated scientists to develop energy systems more sustainable, having as one of the possible alternative the use of solar energy as source for cooling systems. In the field of the sorption cooling, there are three kinds of system: liquid absorption, solid absorption (chemical reaction) and adsorption. The great advantage of adsorption systems over absorption ones is that they can operate without moving parts, having then lower costs of maintenance. Other advantages in comparison with the compression systems are: simple construction, environmentally benign and noiseless. A lot of applications for adsorption cooling systems have been viewed in both developed and developing countries such as: storage and conservation of vaccine, medical products, food conservation (vegetable, meat, fish, etc), refrigeration, air conditioning, chillers and ice production. Adsorption cooling systems and the enhancement of heat and mass transfer inside it is the most important factor to improve the performance of such systems. Thus, great efforts have been made to investigate the transfer occurring in the adsorption and desorption process.

The previous theoretical studies [1-5] were focused on the ideal cycles and did not take into account the heat and mass in the adsorbent bed, these models assumed uniform temperature and uniform pressure to optimize the performance of the system.

This paper presents the study of a tubular adsorber of solar adsorption cooling machine. The modelling and the analysis of the adsorber are the key point of such studies, because of the complex coupled heat and mass transfer phenomena that occur during the working cycle. The adsorber is heated by solar energy and contains a porous medium constituted of activated carbon AC-35 reacting

by adsorption with methanol. This is because of the activated carbon is chemically stable during the adsorption operation. The methanol can be evaporated at a largely temperature below 0 C°, have a high enthalpy of evaporation, its working pressure is always lower than atmospheric pressure.

The simulation technique takes into account the variation of ambient temperature and solar intensity along a simulated day, which is corresponds to a total daily insolation of 26,12 MJ/m² and an average ambient temperature of 27.7 °C [6]. The obtained solution of system's equations, allows to know the daily thermal behaviour of the tubular adsorber (temperature and pressure).

The model is used to study the influence of the adsorber dimensioning (number of tubes inside the adsorber, and the total solar collector type surface on the system's behavior (temperature and pressure).

MATHEMATICAL MODEL

The solar refrigeration system presented in this study consists of the following main elements:

a solar collector coupled to the multi-tubular adsorber filled with the porous medium; a condenser, an evaporator

and a receiver which is used to store the fluid refrigerant coming from the condenser [6]. The adsorptive reactor coupled to the solar collector which has 1 m² surface area, consists of transparent single glass cover, lateral and rear insulation in order to limit the thermal losses, and 8 connected parallel copper tubes, where the total sum of external diameters tubes is equal to 1 m. The porous medium consists of a fixed cylindrical bed of activated carbon grains reacting by adsorption with methanol. It is packed in the annular space between two coaxial tubes. Consequently, the size of adsorbent bed in each tube is defined by (R₂-R₁) (Figure .1). All details of the different constitutions of the adsorber are well presented in our previous studies [7-8-9].

FIGURE 1. Scheme of the adsorptive reactor coupled to the solar collector [6-7]

Adsorption is the important phenomena used in systems' of adsorption refrigeration. It constitutes a solid sorption process by which the binding forces between fluid molecules (adsorbate) and the solid medium (adsorbent) derive from an electrostatic origin or from dispersion-repulsion forces. It is an exothermic and reversible process as a result of the gas-liquid phase change without modification of the solid itself. The adsorbed mass is obtained from the state equation of the bivariate solid-vapour equilibrium using Dubinin- Astakhov model, which is expressed as:

$$m = w_0 \rho_l(T) \exp \left[-D \left(T \ln \frac{P_s(T)}{P} \right)^n \right] \quad (1)$$

The energy liberated during adsorption is called isosteric heat of adsorption and its intensity depends on the nature of the adsorbent/adsorbate pair, the amount adsorbed mass and the latent heat L , it is given as:

$$q_{st} = L(T) + RT \ln\left(\frac{P_s(T)}{P}\right) + \left[\frac{\alpha RT}{n D}\right] \left[T \ln \frac{p_s}{P}\right]^{(1-n)} \quad (2)$$

In order to analyse the evolution of the heat and mass transfer process in the adsorbent bed, this is heart of the system, and to identify the parameters that influence the system performance, a mathematical model has been developed; in order to simplify it. This model is well discussed in our previous work by chekirou et al. [7]. All the basic parameters used in the model are also cited in reference [7].

The energy equation used in this study is given by:

$$\rho_2 \left(cp_2 + m cp_l + \frac{b q_{st}^2}{RT^2} \right) \frac{\partial T}{\partial t} = k \left(\frac{\partial T^2}{\partial r^2} + \frac{1}{r} \frac{\partial T}{\partial r} \right) + \rho_2 q_{st} b \frac{d \ln p}{d t} \quad (3)$$

Where: $b = n D m T^n \left(\ln \frac{p_s(T)}{p} \right)^{n-1}$

The heat losses in the adsorber is represented by the top heat losses coefficient U_{top} , which is given by an ampiric relation, for temperatures ranging between 0° and 200° C with an error lower or equal to $\pm 0.3 W / m^2 K$:

$$U_{top} = \left[\frac{N}{\frac{c}{T_w} \left(\frac{T_w - T_{amb}}{N + f} \right)^e} + \frac{1}{h_v} \right]^{-1} + \frac{\sigma (T_w + T_{amb}) (T^2 + T_{amb}^2)}{(\varepsilon_p + 0.00591 N h_v)^{-1} + \frac{2 N + f - 1 + 0.133 \varepsilon_p}{\varepsilon_g} - N} \quad (4)$$

Where

$$f = (1 + 0.089 h_v - 0.1166 h_v \varepsilon_p) (1 + 0.07866 N)$$

$$e = 0.43(1 - 100/T_w)$$

$$h_v = 2.8 + 3 V$$

$$c = 520(1 - 0.000051 \beta^2) \text{ for } 0^\circ < \beta < 70^\circ$$

Where, β is the collector inclination, it is assumed equal to 37.3° the latitude of Constantine, because it permits to receive the maximum annual energy.

The top heat losses coefficient is used in the limit external boundary condition, to find the adsorber wall temperature.

About the boundary and initial conditions, we consider at the beginning of the cycle, the distribution of temperature of the adsorbent bed and adsorber wall can be considered as uniform and equal to the ambient temperature at the sunrise and the pressure equal to the evaporator pressure. As the geometry of the adsorber is cylindrical, therefore, the boundary condition on the cylinder axis is a symmetry condition.

The solar intensity and ambient temperature are modelled in this study as variants throughout the day (hypothetical clear day). These weather conditions are those of the Constantine region, which is situated in north-east Algeria, at $6^{\circ}, 37'$ East (longitude) and $37^{\circ}, 17'$ North (latitude), with an average altitude of about 625 m. This simulated day corresponds to a total daily insolation of 26.12 MJ m^{-2} and an average ambient temperature of 27.7°C .

The given model requires the simultaneous solution of a set of partial differential and algebraic equations. These equations are discretized by using a fully implicit finite differences method in order to obtain four unknowns: The adsorbent bed temperature, the pressure and the adsorbed mass of methanol during a full cycle.

RESULTS AND DISCUSSION

A computer program was done on the basis of the numerical model, which is well discussed in our previous work by Chekirou et al. [7]. All the basic parameters used in the model are also cited in reference [7].

The estimates of the saturated vapour pressure, the adsorbed phase density and the latent heat of methanol are given by R. C. Weast [10], A. Bejan and A. D. Kraus [11].

The average temperature inside the adsorber during one day is presented in figure 2.

The temperature is considered equal to the ambient temperature in the morning before sunrise and under a low pressure of methanol (equal to the evaporation pressure $P_e = 28.72 \text{ hPa}$). When the adsorber is heated by solar radiation, the adsorbent bed temperature increases rapidly with time. The heating continues until the condensation pressure is reached (equals to $P_c = 216.76 \text{ hPa}$). The reached temperature is known as limit temperature of desorption. The heating continues also as much as the solar radiation is sufficient to increase the temperature of the adsorbent bed and until the maximum regenerating temperature is reached.

Solar flux decreases and the cooling starts down after it reaches the maximum regenerating temperature. The temperature decreases until the pressure becomes equal to that which reigns in the evaporator ($P_e = 28.72 \text{ hPa}$). The reached temperature is known as limit temperature of adsorption.

Cooling continues until the low values of temperatures. The mean of these values corresponds to the initial temperature of a new cycle.

For the effect of the total surface area of the adsorber on the distribution of temperature, from figure 2 we notice that, with the increase in total area of the adsorber, the temperature of the adsorber decreases during the heating phases, and increases during the cooling phases. This can be justified by the fact that, the increase of total surface area induces a reduction in regeneration temperature as it is shown in figure 3. A reduction in regenerating temperature induced a reduction in the performance of the machine as it is found in our previous work [7].

FIGURE 2. Effect of total surface of the reactor on the average temperature inside the adsorber during one cycle

FIGURE 3. Effect of solar collector surface area on regeneration temperature

The pressure behaviour inside the adsorbent bed during one cycle is presented in figure 4. The pressure increases from the initial evaporation pressure $P_e = 28.72$ mbar (equal to the saturated vapour pressure at the evaporation temperature) up to the maximum value corresponding to the condensation pressure $P_c = 216.76$ mbar (equal to

the saturated vapour pressure at the condensation temperature). During the isobaric heating phase, the pressure remains constant and equal to the condensation pressure until the adsorbent bed reaches the maximum regeneration temperature. Then, the pressure starts to diminish down to the initial evaporation pressure and remains constant during the isobaric cooling phase.

About the effect of total surface of the reactor on the pressure inside the adsorber during one cycle, we notice that the increase in surface induced a decrease in pressure during the heating phase, and an increase during the cooling phase. No effect of total surface of the reactor on pressure during the isobaric phases.

Effect of number of tubes on the average temperature inside the adsorber during one cycle is presented in figure 5. It is clear that the increase in number of tubes induced an increase in temperature inside the adsorber during the two heating phases. However, during the cooling phases, the increase in number of tubes induced a decrease in temperature inside the adsorber.

FIGURE 4. Effect of total surface of the reactor on the pressure inside the adsorber during one cycle

FIGURE 5. Effect of number of tubes on the average temperature inside the adsorber during one cycle

The increase of tubes on the pressure inside the adsorber during the cycle induced an increase of pressure during the isotheric heating phase. However, during the isosteric cooling phase, the increase of tubes induced a decrease of pressure. No effect of number of tubes on pressure during the isobaric phases.

FIGURE 6. Effect of number of tubes on the pressure inside the adsorber during one cycle

CONCLUSIONS

A numerical model has been developed in this study in order to show the effect of dimension parameter (number of tubes, total surface area of the solar reactor) on the distribution of temperature and pressure inside the adsorber. The activated carbon AC-35/methanol is used as a working pair. The ambient and solar radiation time variations are taken into account. A uniform pressure and non uniform temperature model is proposed, in order to describe the behavior of heat and mass transfer in the adsorbent bed, using a meteorological data of Constantine for a hypothetical clear day.

ABSTRACT

Different geographic and climatic conditions can create very favorable environments for the development of many plant pests. The protection of agricultural products is very important both to ensure food safety and to contribute to the country economy. The interest in the use of entomopathogens (EPOs) as an alternative to chemical insecticides in the control strategies against plant pests is increasing day by day. Among the entomopathogens, protistan pathogens play an important role as natural suppressor factor in pest insect populations. The present study includes presence of protistan pathogens in the populations of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* from the village Tsilkani in Mtskheta, Georgia. During the study, 160 samples of Chrysomelidae pests were dissected and searched for protistan entomopathogens. Gregarine pathogens were found in the populations of two Chrysomelidae pests, *Chaeotocnema tibialis* and *Phyllotreta atra* in Georgia for the first time. However, any infection was not found in the examined *Leptinotarsa decemlineata* population. The gregarine infection rates were considerably low, 14% for *P. atra* and 15.6% for *C. tibialis* when compared with their occurrence in the populations of the both pests, 8.6-70.3% in *P. atra* and 63.2% in *C. tibialis*, in Türkiye. The present study includes the first records on the occurrence and prevalence of gregarine pathogens in the populations of Chrysomelidae pests in the village Tsilkani in Mtskheta Georgia. However it is needed to increase the number of populations and samples from different locations to represent the entire Georgia. Furthermore, it is needed to investigate other pathogens and parasites and identify each of them at the species level.

Keywords: Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra*, *Leptinotarsa decemlineata*, Georgia

INTRODUCTION

Chrysomelidae is one of the most species-rich and species-diverse groups of the order Coleoptera. This family is commonly known as leaf beetles and has approximately 36000 species in more than 2000 genera into 12 subfamilies (Bouchard et al. 2017). Leaf beetles are insects that depend on the area and structural features of the habitat. Therefore, increasing plant diversity is thought to increase the richness of these insects (Teles et al., 2020). Leaf beetles (family Chrysomelidae) primarily feed on the leaves of plants and they can cause significant damage quickly when occurring

in large numbers. This may become an undesirable situation in agricultural and forest areas and Chrysomelidae species may become widespread agricultural pests. On the other hand, different geographic and climatic conditions can create very favorable environments for the development of many plant pests. Like other insect groups, leaf beetles are affected differently by different habitats.

Today, agricultural pests are generally controlled with chemical pesticides. Chemical pesticides cause insecticide resistance, environmental pollution, toxicity to mammals and other non-target animals (Isman, 2006). Common use of chemical insecticides result in increasing attention given to natural products. Alternative control methods are needed for an effective and efficient fight against plant pests (Freitas et al., 2020).

Biological control using entomopathogens is a promising alternative control. Among the entomopathogens, protistan pathogens can play an important role as natural suppressor factor in pest insect populations in natural conditions. Therefore, studying the presence of protistan entomopathogens in pest populations can provide useful information for detecting natural factors in pest populations.

The present study includes presence of protistan pathogens in the populations of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* in Georgia.

MATERIAL AND METHOD

160 adult samples of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* were collected from the village Tsilkani in Mtskheta in Georgia. After macroscopic examination, they were dissected in Ringer's solution and wet smears were prepared. Host fat body, malpighian tubules, gut epithelium, and hemolymph were examined for the presence of the protistan entomopathogens under a light microscope at $\times 400$ –1000 magnification (Yaman et al., 2019). When an infection with the spore/oocysts of pathogen was observed, a part of the material was used for the preparation of Giemsa-stained smears. Giemsa-stained slides were examined under a light microscope.

RESULTS AND DISCUSSION

The members of the family Chrysomelidae are frequently infected by protistan entomopathogens. Protistan entomopathogens infecting Chrysomelidae have aroused interest as potentially suppressing factors of chrysomelid populations. For that, several new protistan entomopathogen species have been isolated and characterized from these insects recently. Geographic conditions and host plants may influence the diversity of protistan entomopathogens in insects. Therefore, the protistan entomopathogens of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* in Georgia were determined and compared with the presence of their infections in Türkiye.

During the study, 160 samples of three important Chrysomelidae pests were dissected and searched for protistan entomopathogens. Gregarine pathogens were found in the populations of two Chrysomelidae pests, *C. tibialis* and *P. atra* in the village Tsilkani, Georgia for the first time. Seven of 45 *C. tibialis* beetles examined (15.6) in the population of *C. tibialis* collected in Tsilkani, Georgia were found to be infected by the gregarine pathogen. The gregarine infection was considerably low (15.6%) for *C. tibialis* populations in Georgia when compared with its occurrence in *C. tibialis*

populations in Türkiye (Table 1). Yaman (2004) observed gregarine infection in 96 of 152 beetles examined (63.2%) in the population of *C. tibialis* in Trabzon, Türkiye.

The gregarine infection was also considerably low (14%) for *P. atra* population when compared in Georgia when compared with its occurrence in *P. atra* populations in Türkiye (Table 1). Yaman (2004) observed considerable high gregarine infection reaching 70.3% in the populations of *P. atra* at different localities of the Middle and East Black Sea Region of Türkiye.

On the other hand, no protistan entomopathogen other than the gregarine pathogen were observed in the examined *P. atra* and *C. tibialis* beetles in Georgia.. Contrast, two new microsporidian species, *Nosema chaetocnema* (Yaman and Radek, 2003) and *N. tokati* (Yaman et al., 2008) were recorded from *C. tibialis* populations in Türkiye. Furthermore, already known microsporidium species, *Nosema phyllotretae* was recorded from *P. atra* populations in Türkiye (Yaman et al., 2005).

During the study, we also investigated protistan entomopathogens *Leptinotarsa decemlineata* population in Georgia. For this, 15 larvae and 50 adults of *L. decemlineata* were examined for any protistan entomopathogens. Unfortunately, any infection was not found in the examined larvae and adults of *L. decemlineata* (Table 1). However, Yaman et al. (2011) recorded the microsporidium pathogen, *Nosema leptinotarsae* in *L. decemlineata* population in Türkiye. Yaman et al. (2011) found the microsporidian pathogen in both larvae and adults of *L. decemlineata*.

Table 1. Protistan entomopatogen infection in three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* from village Tsilkaniin Mtskheta, Georgia.

Pest species	Number of examined samples	Number of infected samples	Infection rate (%)	Infection rates in Türkiye
<i>Chaeotocnema tibialis</i>	45 ^a	7 ^g	15.6	63.2 ^g (Yaman, 2004)
<i>Phyllotreta atra</i>	50 ^a	7 ^g	14	8.6-70.3 ^g (Yaman, 2002)
<i>Leptinotarsa decemlineata</i>	50 ^a	0	0	1.89 ⁿ (Yaman et al. 2011)
	15 ^l	0	0	4.51 ⁿ (Yaman et al. 2011)

^g Gregarine infection, ⁿ Nosema, ^a Adult, ^l larva

CONCLUSIONS

The present study includes the first records on the occurrence and prevalence of gregarine pathogens in the populations of Chrysomelidae pests in Georgia. When compared the infection rates and infective pathogens, it is seen that it is a considerable difference in the term of infection rates and infective protistan pathogen species between the populations of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* in Georgia and Türkiye. However, it is needed to increase the number of populations and samples from different locations to represent the entire Georgia. Furthermore, it is needed to investigate other pathogens and parasites and identify each of them at the species level.

ABSTRACT

The Indian meal moth (*Plodia interpunctella*, (Lepidoptera; Pyralidae)) is one of the most economically significant pests of stored products globally. Stored product pests cause direct or indirect damage to contaminated food products. This pest lead to weight losses in products, deterioration of seed qualities, and degradation of quality and nutritional values, thereby negatively affecting the national economy. Interest in using entomopathogen as an alternative to chemical insecticides for the control of the pest is increasing day by day. Among entomopathogens, protist pathogens play a significant role as natural suppressive factors in pest insect populations. This study aimed to determine the seasonal distributions of protist pathogens in different populations of *P. interpunctella* in Türkiye during the five years (from 2019 to 2023). During the study, 6.367 *P. interpunctella* larvae, pupae, and adults (4.091 dead larvae, 609 living larvae, 1.330 adults, and 337 pupae) were dissected and examined under a light microscope from 14 different provinces in Türkiye (Ankara, Aydın, Bolu, Denizli, Gaziantep, Isparta, Istanbul, Izmir, Kastamonu, Malatya, Ordu, Samsun, Siirt, and Trabzon). As a result. microsporidian, neogregarine, and coccidian pathogens were observed during the dissections. When the seasonal distributions of microsporidia and neogregarine pathogens were examined seasonally, and significant differences were detected in each season of the year. However, coccidian pathogens could not be analyzed seasonally as they were not observed in different periods. This study is the first to examine the seasonal distribution of protist pathogens in *P. interpunctella* populations in Türkiye in detail. The results confirmed once again that *P. interpunctella* populations in Türkiye contain a considerable amount of protist entomopathogens.

Keywords: *Plodia interpunctella*, protist pathogen, seasonal distribution, Türkiye.

INTRODUCTION

The Indian meal moth, *Plodia interpunctella* (Hübner) (Lepidoptera: Pyralidae), holds a significant position among pests that cause substantial economic damage to stored products (Rees, 2004). *P. interpunctella*, which infests products and leads to both damage and degradation of nutritional quality, feeds and causes damage only during its larval stage. During feeding, it produces silk webs, contaminating food materials. As a result, the infested products suffer from weight loss, reduced commercial value, and decreased seed quality (TAGEM, 2008; Kaymakçı, 2022). The majority of the products damaged by *P. interpunctella* are foods consumed by humans. Fumigation with chemical insecticides is not considered suitable due to the harmful side effects on the environment and human health. Additionally, *P. interpunctella* has been reported to show resistance to many insecticides (Attia, 1977). Due to these impacts, it has become necessary to develop eco-friendly

control methods that have no harmful side effects on the environment and non-target organisms. The most promising results in controlling *P. interpunctella* have been obtained from trials using its natural enemies (Schöller and Filinn, 2000; Grieshop, 2005; Shojaaddini et al., 2012). Interest in the use of entomopathogens as an alternative to chemical insecticides in controlling this pest is increasing day by day (Yaman, 2012). Among entomopathogens, protist pathogens play a significant role as natural suppressive factors in pest insect populations. This study aims to determine the seasonal distributions of protist pathogens in different populations of *Plodia interpunctella* in Turkey over a period of five years (2019-2023).

MATERIAL AND METHOD

During the study, 6.367 specimens including larvae, pupae and adults of *P. interpunctella* were collected from fourteen regions (Ankara, Aydın, Bolu, Denizli, Gaziantep, Isparta, İstanbul, İzmir, Kastamonu, Malatya, Ordu, Samsun, Siirt, Trabzon) of Türkiye (Table 1).

Microscopic Examination

P. interpunctella larva, pupa and adult samples were dissected in Ringer's solution and then prepared wet smears including host fat body, malpighian tubules, gut and hemolymph were examined for presence of protist infections under a light microscope at a magnification of 400– 1000 ×. When an infection was found, the slides were air-dried and fixed with methanol, then stained with freshly

prepared 5% solution of Giemsa stain. They were then washed in running tap water, air-dried and examined under a microscope.

RESULTS AND DISCUSSION

During the study, 6.367 of *P. interpunctella* samples including larvae, pupae and adults were dissected and searched for protist pathogens such as microsporidia, coccidia and neogregarines in the fourteen localities of Turkey between the years 2019-2023. Protist infections were confirmed by observation of their characteristic spores/oocysts. Three different protist pathogens, microsporidium, coccidian and neogregarine were observed in *P. interpunctella* populations.

The seasonal density of the microsporidia pathogen was examined in detail. According to the data obtained throughout the study, the infection rate was quite high in the first six months of 2019 (January, February, March, April, May, and June), reaching 42%, but it was found to drop to as low as 20% in the second half of the year (Figure 1).

Figure 1. The microsporidia density detected in 2019

In the first six months of 2020, the infection rate was observed to be 13%, while in the last six months of the year, it increased to as much as 29% (Figure 2).

Figure 2. The microsporidia density detected in 2020

When looking at the infection intensity in 2021, it was observed that, similar to 2019, the infection rate was high in the first six months of the year, followed by a decline in the last six months (Figure 3).

Figure 3. The microsporidia density detected in 2021

When examining the infection rate in 2022, it was found that, similar to 2019 and 2021, the infection was high in the first half of the year, followed by a slight decrease in the second half (Figure 4).

Figure 4. The microsporidia density detected in 2022

In 2023, the infection rate was found to be consistent, with the same level of infection observed in both the first and second halves of the year (Figure 5).

It is known that the development of *P. interpunctella* is influenced by temperature, with development accelerating at optimal temperature levels and slowing down at temperatures below this level. In storage facilities or homes where temperature is uncontrolled, *P. interpunctella* larvae are known to enter a diapause stage during cold months. However, when favorable environmental conditions are restored (especially in early spring or when homes remain warm even during winter

months), a significant increase in moth populations occurs (Mason, 2002; Güngör, 2014). It has also been reported that if the temperature does not drop too low, the moth does not enter the diapause stage (Prevett, 1971). In our study, seasonal findings of *V. plodiae* isolate TR density generally showed a high infection density in the first six months of the year (Figures 1, 3, 4, and 5). This increase is thought to be due to the temperature and humidity levels in home and storage environments. When looking at the infection density in the last six months of the year, an increase in the infection rate was observed in 2020 (Figure 2). It is believed that the increase in infection during these months was due to the provision of optimal temperature conditions for *P. interpunctella* development, given that these are the warm months of the year. Throughout the study, it was possible to find heavily infested products even in winter, especially in field studies conducted in homes.

Figure 5. The microsporidia density detected in 2022

When the seasonal density of the neogregarine pathogen was examined, it was found that infection density increased in both the first and second halves of the year in 2019, 2020, 2021, and 2023 (Figures 6, 7, 8, and 10). This continued high infection rate in the second half of the year is also thought to be due to the optimal temperature conditions in home environments, which accelerate the development of *P. interpunctella*. Only in 2022 was it observed that the infection density decreased from 19% in the first half of the year to 15% in the second half (Figure 9).

Figure 6. The neogregarine density detected in 2019

Figure 7. The neogregarine density detected in 2020

Figure 8. The neogregarine density detected in 2021

Figure 9. The neogregarine density detected in 2022

Figure 10. The neogregarine density detected in 2023

According to the study results, seasonal variations in the density of the detected pathogens were observed. These changes could be related to population density, and it is speculated that in dense populations, the rate of infection might be higher due to the increased horizontal transmission within the population.

When the seasonal distributions of the microsporidia and neogregarine pathogens were examined (the first six months of the year: January, February, March, April, May, June and the last six months of the year: July, August, September, October, November, December), significant differences were observed in each season. However, the coccidia pathogen could not be analyzed seasonally as it was not detected during different periods, making analysis impossible.

CONCLUSIONS

This study is the first to detail the seasonal distribution of protist pathogens in *P. interpunctella* populations in Turkey. The results confirm once again that *P. interpunctella* populations in our country contain a significant density of protist entomopathogens. McLaughlin (1971) noted that protozoan pathogens are generally the most suitable organisms for long-term pest population control. The current study has identified that the entomopathogenic protists detected are significant suppressive factors in the natural populations of the pest and are found to be widespread throughout the country. The obtained results encourage the use of protists in biological control against *P. interpunctella*.

ABSTRACT

Honey is a natural carbohydrate produced by honeybees. Honeybees are foragers that produce honey from pollen and nectar. Like all living organisms, honeybees require nutrients, including minerals and water, in order to reproduce, grow and develop. The aim of this study was to determine the elemental content of honeybee, sunflower honey, sunflower and bee drinking water samples, and to identify any potential correlations between element concentrations in the samples. This study was conducted in Enez, Edirne, Turkey. Samples of bee drinking water (n = 10), sunflower (n = 10), sunflower honey (n = 10) and dead honeybee (n = 10) were collected from apiaries in the beekeeping area in 2023. In this study, the highest element in honey samples was determined as potassium and the lowest element was determined as cobalt. In the study, the highest element in honeybee samples was determined as potassium, and the lowest element was determined as selenium. In the study, the highest element in sunflower samples was determined as potassium, and the lowest element was determined as molybdenum. In the study, the highest element in bee drinking water samples was sodium, while cobalt content was not detected. In this study, a significant positive correlation was determined between water and honey for molybdenum ($p < 0.01$), and a significant negative correlation between water and honeybees for zinc ($p < 0.01$), as well as a significant positive correlation for molybdenum ($p < 0.01$). No significant correlation was identified between sunflower-honeybee and sunflower-honey. This study demonstrated the elemental content of honeybee, honey, sunflower and bee drinking water, as well as the correlations between the samples in terms of elemental content.

Keywords: Bee drinking water, Honey, Honeybee, Minerals, Trace elements.

INTRODUCTION

Honey is a natural carbohydrate substance produced by honeybees from the honey essence and nectar of various plants and contains many macro elements and trace elements that are carried from the plant nectar (Bilandžić et al. 2011; Silici et al. 2016). Botanical factors have a great influence on the trace element content of honey (Bogdanov et al. 2007). Honeybees are long-range foragers that produce honey from the pollen and nectar they collect from plants and, they are managed in colonies consisting of 10,000 to 80,000 individuals (Cunningham et al. 2022). Like other living organisms, honeybees require carbohydrates, protein, fat, vitamins, minerals and water in their diets for reproduction, growth and development. Their nutrition is completely dependent on the flora (Özbakır and Alişiroğlu 2019). Honeybees collect nectar, pollen and water to meet these requirements. Honeybee try to meet their water needs by searching for it in almost every source close to their colonies. Water can provide the necessary minerals (Ellis et al. 2010). It is reported that the

deficiencies of some elements in pollen are the nutrients that limit the growth and development of honeybees. In addition, it is stated that the lack of phosphorus (P) in sunflower pollen can negatively affect the growth and development of bees (Filipiak et al. 2017). Several studies have been reported on the element content of honey and honeybees (Silici et al. 2016; Bayram et al. 2020; Hungerford et al. 2020; Murashova et al. 2020).

The aim of this study was to determine the elemental composition of honeybee, honey, sunflower and bee drinking water samples and possible correlations between elemental concentrations in the samples in Enez, Edirne, Turkey.

MATERIALS AND METHODS

All samples were collected from the apiaries located area of intensive beekeeping in 2023, Enez, Edirne, Turkey. These apiaries were located around the agricultural area. Bee drinking water (n=10), sunflower (n=10), sunflower honey (n=10) and dead honeybee samples (n=10) were collected from the area. Recently deceased honeybees (for each sample, 50 to 80 forager bees) were collected from at a maximum distance of 1 m from the hive, respecting the colony, without opening or disturbing the hive. All honey samples (100 g) were placed in sterile plastic bottles and transported to the laboratory. Honey samples were stored at 4-8 °C until analysis. Honeybee and sunflower samples were dried and stored at -20 °C until it was analysis. Water samples were collected from water sources where bees consume water in the area. Water samples were acidified and stored at 4°C until chemical analysis.

Sample Preparation and Elemental Analysis

The concentrations of elements in all samples were analyzed using an Agilent Technologies 7700 Inductively Coupled Plasma-Mass Spectrometer (ICP-MS). These measurements were conducted by the Technology Research and Development Application and Research Center (TUTAGEM) at Trakya University. TUTAGEM used the EPA 200.8 method (EPA 1994) for the analysis of water samples and the method adapted from Lee et al. (2022) for the analysis of honeybee, honey and sunflower samples. The methods used by TUTAGEM for sample analysis are detailed below. The calibration of the device was done by the Research Center using certified reference material.

Blank sample preparation: 2 mL of 30% H₂O₂ (MERCK) and 8 mL of 65% HNO₃ (MERCK suprapur) were taken into the microwave vial and processed in the microwave combustion system (Mars 6, CEM, USA) at 200°C for 45 minutes. Then, 9 mL of ultrapure water was added to the tube to be analyzed and 1 mL of the acid solution obtained from the digestion process was taken.

Preparation of Honeybee, Honey and Sunflower Samples: The following method was used to prepare honey, honeybee and flower samples, with each sample being prepared and analysed separately. 0.5 g samples were weighed into microwave vials. 2 mL of 30% H₂O₂ and 8 mL of 65% HNO₃ (suprapur) were added to them and processed in a microwave combustion system (Mars 6, CEM, USA) at 200°C for 45 minutes. Thus, organic compounds in the sample were removed and inorganic compounds were allowed to pass into the acid solution. Then, 9 mL of ultrapure water was added to the tube to be analyzed and 1 mL of the acid solution obtained from the combustion process was taken.

,

Preparation of Water Samples: Water samples were filtered using 0.45 micron filters. Then 10 ml of filtered water samples were taken into 15 ml tubes. 200 μ L of 1+1 HNO₃/ultrapure water mixture was added to acidify and made ready for analysis.

Data analysis

Statistical calculations were performed using SPSS (ver. 15.0, IBM, USA). Data were presented as mean and standard deviation. Pearson's correlation analysis was conducted to determine the association between the variables.

RESULTS

The concentrations of elements determined in the samples were shown in Table 1 and Table 2. Potassium (K) is the most abundant macroelement (mean concentration 0.96 g/kg) in honey samples. In this study, the lowest level of macroelement in honey was magnesium (Mg) (mean concentration 0.02 g/kg). In the present study, K was the most abundant mineral (mean concentration 7.63 g/kg) in honeybee samples. The most abundant element in the sunflower was K (mean concentration 23.17 g/kg), while the least abundant element was molybdenum (Mo) (mean concentration 0.07 mg/kg). The highest macroelement in the water was sodium (Na) (mean concentration 67.22 mg/L), the lowest macroelement was P (mean concentration 0.05 mg/L). No cobalt (Co) was detected in the water. The correlation results of the study are shown in Table 3. In this study, a significant positive correlation was determined between water and honey for Mo ($p < 0.01$), a significant negative correlation between water and honeybees for zinc (Zn) ($p < 0.01$), and a significant positive correlation for Mo ($p < 0.01$). No significant correlation was found between sunflower-honeybees and sunflower-honey.

Table 1. Element Content of Honey, Honeybee, Sunflower (Mean $\pm$ Standard Deviation)

Elements	Honeybee (Dry weight)	Honey	Sunflower (Dry weight)
Ca	0.77 $\pm$ 0.08	0.08 $\pm$ 0.01	2.47 $\pm$ 0.07

*Correlation is significant at the 0.05 level (2-tailed). **Correlation is significant at the 0.01 level (2-tailed).

DISCUSSION

Consistent with the results of this study, K was observed to be the most abundant element in honey in studies conducted in various countries such as Turkey (Tutun et al. 2019), Bulgaria (Atanassova et al. 2016) and Serbia (Ćirić et al. 2021). The concentration of calcium (Ca) found in this study was lower than the values obtained for honey samples collected from Iran (Arabameri et al. 2024) but higher than the levels obtained in Turkey (Kılıç Altun et al. 2017; Tutun et al. 2019). The mean Na of honey determined in this study was lower than the value (99.7 mg/kg) reported by Hungerford et al. (2020), while the determined result was higher than the results reported in Iran (Arabameri et al. 2024), Bulgaria (Atanassova et al. 2016) and Serbia (Ćirić et al. 2021). The P value obtained in our study was higher than that determined in honey by Atanassova et al. (2016) and Hungerford et al. (2020). The Mg level in our study was found to be lower than the results reported by Altunatmaz et al. (2019) and Tutun et al. (2019), while it was consistent with the result reported by Perna et al. (2021). The mean copper (Cu) concentration determined in the present study was higher than 243 µg/kg determined by Aghamirlou et al. (2015) in Iran, 0.35 mg/kg found by Murashova et al. (2020) in Ryazan region from Russia, 68.5 ppb reported by Kılıç Altun et al. (2017) and 0.38 mg/kg determined by Tutun et al. (2019) in Turkey. But Cu concentrations in this study were lower than those reported by Altunatmaz et al. (2019) and Scivicco et al. (2022) in honey samples from Turkey and Italy (11.03 µg/g and 1049 µg/kg, respectively). Aghamirlou et al. (2015) reported that the differences in the Cu content of honey were due to the use of different fertilizers or diversity of crop management practices in the region studied. This may be the reason why the honey Cu content determined in this study differs from the results of other studies. The mean concentration of chromium (Cr) was lower than those determined in Iran (Aghamirlou et al. 2015) and Turkey (Altunatmaz et al. 2019). The mean Cr level determined in the present study was higher than 17.57 µg/kg reported by Perna et al. (2021) in Italy. The mean Zn concentration in this study was higher than that found in Turkey, Australia, Russia and Italy (Tutun et al. 2019; Hungerford et al. 2020; Murashova et al. 2020; Perna et al. 2021), but lower than that reported by Altunatmaz et al. (2019). The mean selenium (Se) concentration in this study was lower than that reported by Altunatmaz et al. (2019) (2.183 µg/g), but higher than that reported by Hungerford et al. (2020) (0.0052 mg/kg). Similar result were also reported in previous study in Turkey (Kılıç Altun et al. 2017). Atanassova et al. (2016) determined the Co content in honey collected from two different areas to be 0.01 and 0.02 mg/kg, respectively. This result is consistent with the result of the present study. The mean Co level was higher than that determined in Australia, Italy and Kosovo (Hungerford et al. 2020; Perna et al. 2021; Kastrati et al. 2021). Kanbur et al. (2021) determined that the mean manganese (Mn) level in chestnut honey was 19.49 mg/kg. Perna et al. (2021) found the Mn content of honey to be 1603.06 µg/kg and Scivicco et al. (2022) found the Mn level of honey to be 881 µg/kg. Altunatmaz et al. (2019) reported an average Mn level of 1.985 µg/g in honey samples collected from different regions of Turkey. While the honey Mn concentrations reported in the above mentioned studies were higher than those found in the present study, the 45.6 ppb reported by Kılıç Altun et al. (2017) was lower, and the 0.25 mg/kg reported by Tutun et al. (2019) was comparable to the levels observed in this study. In this study, the mean Mo content of honey was higher than those from Australia (0.0115 mg/kg) (Hungerford et al. 2020) and Italy (4.71 µg/kg) (Perna et al. 2021), but lower than the 0.078 ppm reported by Perna et al. (2012).

The Cr content of honeybees determined in this study was higher than the results of the study conducted in Nigeria by Adeoye et al. (2021). Murashova et al. (2020) determined Zn and Cu levels in honeybee samples collected in Russia. The levels of Zn and Cu in this study were higher than those reported in bee samples from Russia. In another study, Goretti et al. (2020) reported mean concentrations in honeybee samples from Umbria (central Italy) as follows: Zn 132.47 mg/kg, Cr 0.27 mg/kg, Cu 14.39 mg/kg and Mn 98.98 mg/kg. In comparison with the above mentioned study, the Zn value obtained in the present study was seen to be lower, while the Mn, Cr and Cu levels were higher.

Zarić et al. (2016) analyzed metals in honeybee samples. In a rural area with agricultural and forested areas, similar to the sampling site in this study, the levels of Cr, Co, Cu, Mn and Na were found to be lower than those observed in this study, while the Zn concentration was comparable to presented results.

Tokatlı (2019) collected drinking water samples from 30 stations in the Ergene River Basin during the summer season. In that study, the mean contents of Mg (12735 ppb), Na (73417.85 ppb), Co (0.12 ppb), Zn (18.73 ppb), Mn (5.13 ppb), Se (10.07 ppb), Mo (19.37 ppb) were higher than those observed in the present study, whereas the mean contents of Ca (24479 ppb), K (1335 ppb), Cr (3.47 ppb) and Cu (1.11 ppb) were lower. The levels of Zn (18.75 mg/kg) and Cu (4.33 mg/kg) in plant samples reported by Murashova et al. (2020) were lower than the results of this study.

CONCLUSION

In this study, honeybee, honey, bee drinking water and sunflower samples were analyzed by ICP-MS. In the study, the highest element concentration was determined to be potassium in honeybee, honey, and sunflower samples, and sodium in water samples. The lowest element concentrations were found to be selenium in honeybee samples, cobalt in honey and molybdenum in sunflower samples. Cobalt was not detected in water samples. In this study, a significant positive correlation was found between water and honey for molybdenum, a significant negative correlation between water and honeybee for zinc, and a significant positive correlation for molybdenum. No significant correlation was found between sunflower-honeybee and sunflower-honey.

ABSTRACT

The rapid advancement of digital transformation in agricultural technologies in recent years has led to a growing emphasis on artificial intelligence (AI)-based approaches. This study systematically examines the applications of Generative Adversarial Network (GAN) models in smart agriculture applications. The potential offered by GAN-based AI solutions in fundamental agricultural activities such as plant breeding, animal husbandry, and soil characterization is highlighted. GAN applications are detailed through current studies in the literature on topics such as plant health detection, weed control, phenotyping, stress tolerance assessment, harvest timing, and product quality analysis, underscoring their significance in enhancing agricultural productivity and promoting sustainable practices. In animal husbandry, GANs are particularly notable for their success in synthetic data generation and classification in areas such as animal health monitoring, behavioral analysis, and image-based growth monitoring. In soil studies, GAN-based models have been shown to produce highly accurate synthesized images for the development of maps of soil structure, moisture content, and nutrient distribution, making significant contributions to precision agriculture applications. Furthermore, strengthening data infrastructure, integrating technological solutions into agricultural systems, increasing interdisciplinary collaborations, creating open-access, high-quality datasets, and developing application-oriented standards will enable more effective use of GAN technologies in agricultural research and applications. Consequently, GANs are positioned to play a pivotal role in the digital transformation of agriculture, and leveraging their capabilities in alignment with sustainable agriculture goals is imperative.

Keywords: Machine learning, Generative adversarial networks, Smart agriculture

INTRODUCTION

Due to adverse developments in global factors such as population growth, climate change, and environmental pollution, there is growing concern both about the preservation of biodiversity and the need to ensure productivity and sustainability in agricultural production. In this context, the demand for sustainable and intelligent solutions is steadily increasing. It is anticipated that the effective use of advanced technologies such as artificial intelligence (AI) and machine learning (ML) in the agricultural sector will accelerate optimization processes aimed at addressing these challenges (Bao and Xie, 2021).

In recent years, artificial intelligence-supported computer vision systems, Internet of Things (IoT-edge) technologies, robotics, smart automation solutions, and microclimate controllers, systems

based on machine learning, have gained increasing importance. These systems are effectively utilized not only in research areas such as early detection of plant and animal diseases, yield prediction, and phenotyping, but also in the development of smart greenhouses, barns, and irrigation systems (Sengupta et al., 2021; Olasehinde et al., 2023; Mohammed et al., 2024). However, agricultural data can be affected by seasonal, geographical, and biological factors, which poses various challenges in data prediction processes. Additionally, the lack of sufficient labeled data in visual-based applications such as disease detection, land analysis, and crop classification can limit the performance of machine learning models (Yang et al., 2021). In this context, Generative Adversarial Networks (GANs), an unsupervised learning-based subfield of machine learning have recently come to the forefront, as they enable the transformation of datasets collected under varying conditions into balanced datasets. GANs have attracted significant attention in areas such as image synthesis, data augmentation, and predictive modeling, and have increasingly been adopted in smart agriculture applications (Akkem et al., 2024; Awate & Nagne, 2025).

The aim of this study is to examine the conceptual foundations of Generative Adversarial Network (GAN) models and to highlight their role and significance within smart agriculture applications. Accordingly, this review presents examples and explanations of GAN implementations across various domains, including plant and animal production, soil morphology and structure, as well as land use prediction. Furthermore, the review provides a comprehensive evaluation of the potential challenges associated with the use of these technologies and outlines future directions for research and development.

GENERATIVE ADVERSARIAL NETWORKS (GANs): BASIC CONCEPTS

GANs, as a popular machine learning model among artificial neural networks, consist of two complementary neural networks: (i) the generator and (ii) the discriminator. The generator is responsible for producing synthetic data that closely resemble real data, while the discriminator evaluates whether the generated data are real or artificial. Through the adversarial interaction between these two networks, GANs establish a self-supervising model architecture (Shah, 2022).

Owing to their ability to generate synthetic data, GANs offer a significant advantage in agricultural studies where datasets are often limited or imbalanced. In the agricultural sector, various GAN applications have been developed to address specific problems or focus on particular data types. These applications are briefly described below:

- a) *Deep Convolutional Generative Adversarial Networks (DCGAN)*: This is an enhanced version of the traditional GAN architecture, incorporating deep convolutional neural networks (CNNs). DCGANs are effectively used for generating more stable and realistic outputs from visual data (Guo et al., 2021; Espejo-Garcia et al., 2021).
- b) *Semi-Supervised GAN*: This model is applied in situations where only a portion of the training data is labeled. It leverages the limited labeled data to extract meaningful representations from larger unlabeled datasets (Kerdegari et al., 2019).
- c) *Cycle-Consistent GAN (CycleGAN)*: This architecture enables transformation between two different datasets (e.g., diseased vs. healthy) without requiring one-to-one pairing of samples for training (Barth et al., 2020).
- d) *Boundary Equilibrium Generative Adversarial Network (BEGAN)*: BEGAN is a balance-oriented GAN variant that evaluates the quality of generated samples based on reconstruction errors (Luo et al., 2020).
- e) *Conditional Generative Adversarial Network (CGAN)*: In this model, data generation is conditioned on specific inputs such as labels, temperature, or soil type. CGANs allow for customized data generation based on crop type, region, or climatic conditions, and are used in

applications such as plant growth simulation and visual annotation (Olatunji et al., 2020; Singh et al., 2021).

- f) *Self-Attention Generative Adversarial Network (SAGAN)*: Thanks to its attention mechanism (self-attention), it is used to model visual details and relationships between distant regions. It enables high-quality and detailed image synthesis during the generation process (Li and Tang, 2020).
- g) *Conditional Tabular GAN (CTGAN)*: This GAN model was developed to generate artificial tabular data and is particularly used in structural data synthesis (Ahmed et al., 2021).
- h) *Wasserstein GAN (WacGAN)*: Using Wasserstein distance as the loss function, this model aims to mitigate the "mode collapse" problem. Thanks to these features, it is effectively used in the prediction of complex datasets such as weather patterns and soil samples (Madsen et al., 2019).
- i) *Customized GAN*: These GAN models are designed to develop functionality for specific agricultural problems by combining or adapting existing GAN types (Chou et al., 2019).
- j) *Transformer-based GAN (TransGAN)*: GAN architecture uses transformer blocks instead of convolutional neural networks (CNNs). It is particularly successful in producing high-resolution and detailed images thanks to its attention mechanism (Wang & Xiao, 2021).

USE OF GANs IN SMART AGRICULTURE APPLICATIONS

GANs are primarily used in smart agriculture applications in crop and animal husbandry, but also in various smart agriculture areas such as soil morphology, structure, and land use estimation. Therefore, examples of smart agriculture applications are presented under three subheadings: (i) GANs in plant breeding, (ii) GANs in animal husbandry, where livestock and aquaculture are considered together, and (iii) GANs in soil properties and agricultural area change estimation.

GANs IN PLANT CULTIVATION

To date, applications of GANs in plant cultivation have encompassed research areas such as plant phenotyping, detection of plant health in terms of pathogens and pests, weed identification, determination of product quality traits, post-harvest quality assessment, as well as monitoring and detection in biotechnological studies.

The investigation of the effects of various pests and pathogens on plant traits constitutes a significant area of research in plant cultivation. These agents, particularly those adversely affecting photosynthesis in leaves, pose a serious threat to plant development and productivity. Such impacts can slow down the natural growth processes of plants, reduce crop yields, and consequently lead to economic losses. In this context, early detection of pests and pathogens is of paramount importance (Hu et al., 2019; Maqsood et al., 2021). In a study employing GANs, synthetic images were generated using a Conditional Generative Adversarial Network (C-GAN) for the detection of diseases on tomato leaves. These synthetic data were then used to train a DenseNet121 model via transfer learning. The model was tested on the PlantVillage dataset and achieved accuracy rates of 99.51%, 98.65%, and 97.11% for 5, 7, and 10 disease classes, respectively. This work demonstrated superiority over existing methods by improving classification accuracy through GAN-based synthetic data generation (Abbas et al., 2021). Similarly, weeds compete with crops for nutrients, negatively affecting yield. Research utilizing GANs for weed control has been reported to offer effective solutions in this field (Khan et al., 2021; Espejo-Garcia et al., 2021). For instance, in a study by Li et al. (2024), a GAN model enhanced with a channel attention mechanism (CA-GAN) was employed to generate realistic synthetic weed images. These images were used to train deep learning-based weed detection models. The model

achieved an accuracy rate of 93.46% on the ISAS dataset, demonstrating the potential of GAN-based data augmentation to improve model performance under limited data conditions.

Abiotic stress factors such as temperature, drought, and salinity also exert direct and adverse effects on plant yield. Developing stress-resilient varieties requires appropriate species and phenotype selection alongside effective breeding strategies. In this context, a study by Kaushik (2025), GANs were used as a part of multilayered artificial intelligence approaches. GANs were utilized to propose novel gene combinations for high-altitude extremophile plants thriving under extreme environmental conditions. This AI-based platform integrated multi-omics data and environmental simulations to successfully predict plant growth and stress tolerance. It was reported that the GAN-suggested gene combinations improved stress tolerance by up to 15%. This study demonstrates the innovative and promising potential of GANs as tools for developing abiotic stress-resistant plant varieties.

Similarly, successful phenotyping applications have been found in smart greenhouse systems integrated with GANs (Giuffrida et al. 2017; Zhu et al. 2018; 2020; Zahid 2025). In this context, in a study conducted by Liu et al. (2023), ripeness stages and damage levels of apple fruits were classified using data augmentation with GAN. In this study, a lightweight CNN-integrated GAN architecture was developed, generating realistic synthetic apple images in datasets with no class imbalance, thereby improving the recognition accuracy of the model. The results showed 95.6% accuracy, 93.8% recall, and 95.0% overall success rate in apple fruit ripeness and damage classification. This study demonstrates that GAN-based approaches can be effectively applied even with limited data for fruit ripeness estimation and phenotyping, especially in greenhouse conditions. The ARIGAN study conducted by Valerio Giuffrida et al. (2017) developed a GAN model that generates synthetic images dependent on the leaf count of *Arabidopsis thaliana* plants. The model produced realistic rosette images for different leaf counts, thus creating new image datasets that can be used for data augmentation in plant phenotyping. The model developed using these synthetic images resulted in a significant improvement in leaf count accuracy. This study demonstrates that GANs offer an effective solution for plant phenotyping in greenhouses or controlled environments, increasing data diversity, addressing the lack of labeled data, and enhancing data-based model training processes using synthetic images. Furthermore, GANs are reported to be effective in solving object detection problems associated with vision systems in intensively cultivated agricultural areas (e.g., orchards) (Fei et al., 2021). In this context, a study by Fei et al. (2021) generated synthetic fruit images from a 3D model using a semi-semantic constrained GAN model. This method preserved fruit positions and yielded images compatible with real-world datasets. The resulting synthetic images strengthened the training dataset, particularly in dense orchard environments where challenges such as overlap and hidden regions existed, and significantly increased the accuracy of object detection models by reducing the need for data labeling.

Through control systems integrated with GANs, quality standards and fruit deformities can be reliably detected. The identification of deformities and decay in commercially valuable fruits such as lemons, coffee beans, and kiwis holds significant importance. In such quality inspections, GAN-based data augmentation approaches provide an effective solution to improve overall model performance (Lu et al., 2022). For instance, in a study by Bird et al. (2022), Conditional GAN (cGAN)-based data augmentation was applied for lemon surface quality and defect classification. To expand the limited number of existing lemon images, synthetic images of defective fruits were generated using cGAN, and a fine-tuned VGG16-based classifier was trained with this enhanced dataset. As a result, the model's classification accuracy improved from 83.77% to 88.75%, substantially reducing generalization issues caused by data scarcity.

Table 1 presents some examples of studies conducted to date using GAN-based methods in plant breeding. The table summarizes the plant material used in each study, the specific applications to

which GAN models have been applied (e.g., disease detection, phenotyping, quality assessment, etc.), and metrics related to model performance, such as accuracy and F1 score.

GANs IN ANIMAL HUSBANDRY (FARM ANIMALS AND AQUACULTURE)

There are various GAN applications in farm animals and aquaculture for research areas such as animal phenotyping, determination of health status, and determination of yield and quality traits in animal products.

Animal production, which constitutes a significant portion of the food industry, continues to present numerous challenges, including animal welfare, ensuring quality standards, and establishing disease-free facilities. The inadequacy of traditional methods in these areas allows GAN models to offer remarkable solutions, particularly for needs such as image generation, data augmentation, and modeling phenotypic variation. For example, GAN-based systems integrated with IoT technologies have been reported to yield effective results in improving product quality and monitoring animal health

in poultry farming (Elmessery et al., 2023). Similarly, in the field of chick breeding, GAN models trained with data obtained from time sensors have demonstrated high accuracy in distinguishing healthy from diseased individuals (Abdoli et al., 2018).

GANs are also widely used in areas such as animal behavior analysis and phenotyping. They offer an effective alternative, particularly in situations where collecting and labeling animal data is difficult (Li et al., 2023). For example, in a study conducted by Shang et al. (2023), a GAN model was trained based on differences in hair shape between Angora goats and sheep and was found to be successful in phenotypic identification of Angora goats. On the other hand, in a study conducted to assess animal meat quality, fatty acid profiling was performed on sheep, beef, and pork; the resulting data was analyzed using a GAN model for quality classification (Cui et al., 2024).

In aquaculture, digital underwater monitoring methods are preferred to identify cultivated species, particularly those at risk from adverse underwater conditions, and to accurately identify underwater species (Li et al., 2021). Among these digital approaches, the success of GAN-based applications in species identification using visual data is noteworthy. Indeed, a GAN model trained on shrimp egg datasets has been reported to yield effective results in this field (Zhu et al., 2017).

GAN-based studies used in animal production systems in the context of smart agriculture applications are presented in Table 2. This table summarizes the animal materials used, the purpose for which GAN models were chosen, and the basic evaluation criteria for the performance of these models.

Table 2. Applications of GAN models in livestock and aquaculture systems

GANs IN PREDICTING SOIL PROPERTIES AND AREA CHANGE

GAN models are used within the scope of smart agriculture applications in many soil-focused studies such as determining soil temperature, estimating the properties of soil nutrients and detecting changes in agricultural land use.

Soil physical properties such as texture, porosity, and aggregate structure; chemical factors such as pH, cation exchange capacity, and ion activity; and biological elements such as microbiota population and activity directly affect plant growth and development (Delgado and Gomez, 2024). Furthermore, the uptake of macronutrients (N, P, K, etc.) and micronutrients (Fe, Zn, Mn, etc.) by plants is also largely dependent on climatic variables such as temperature and precipitation (Voltr et al., 2021). Accurately modeling and analyzing these complex interactions is of strategic importance for the design of sustainable agricultural systems and adaptation to climate change (Jansson & Hofmockel, 2020). Modeling approaches provide effective results in predicting the effects on root development, plant nutrition, and yield resulting from the interaction of environmental factors such as temperature and precipitation, as well as properties related to soil structure and morphology. One of the studies conducted in this direction was conducted by Li et al. (2020). In this study, a GAN model was trained to estimate subsoil temperature using meteorological data such as wind speed and humidity. Following training, the model successfully predicted soil temperature at a depth of 5 cm. Similarly, in another study by Jiang et al. (2023), alpine meadow soil samples from the Qinghai-Tibet Plateau were evaluated and a GAN model was trained. This model was found to be effective in estimating the ratios of nitrogen, soil organic matter, potassium oxide, and phosphorus pentoxide to varying levels of accuracy at the regional level.

Table 3 presents some GAN-based sample studies on soil property determination and land use change prediction, along with GAN performance metrics for these studies.

Table 3. Applications of GAN models for soil property analysis and land use change estimation

Usage Area	Review Material	Performance Measure / Ratio	References
Soil temperature (Ts)	Hourly meteorological data, including air temperature (Ta), wind speed (W), relative humidity (RH), solar radiation (SR), and vapor pressure deficit (VPD)) from two stations in China (Changbai Mountain and Haibei) were used for model training.	Model performance for estimating 5 cm soil depth temperature; Model efficiency coefficient: 0,915 Willmott index of agreement: 0,978 Legates and McCabe index: 0,686	<i>Li et al. (2020)</i>
Soil nutrients	It was used to estimate soil nutrients (nitrogen (TN), soil organic matter (SOM), total potassium oxide (TK ₂ O), and phosphorus pentoxide (TP ₂ O ₅)) in degraded Alpine Grasslands in the Qinghai-Tibetan Plateau.	Accuracy rate; 50-60 for TN 25-35 for SOM 30-40 for TK ₂ O 30-35 for TP ₂ O ₅	<i>Jiang et al. (2023)</i>
Detection of changes in land use	UKCEH Land Cover Map data was used.	The model covers a transition between arable and grazing land cover classes by 71%.	<i>Harrison (2025)</i>

		It predicted spatial patterns among forested, arable, grassland, freshwater, and urban areas 89% of the time.	

Soil-based area modification refers to the optimization of land use and agricultural activities in a region based on the physical, chemical, and biological properties of the soil. This approach, particularly in smart agriculture applications, enables land management strategies to be addressed with different soil management strategies by taking soil variations into account (Taghizadeh-Mehrjardi et al., 2020; Pandey and Pandey, 2023). In a study by Harrison (2025), a GAN model was trained using data from 1990 to validate the original UKCEH Land Cover Map data from 2019. This model was found to be effective in accurately predicting arable land, pasture, freshwater, and urban areas.

FUTURE PERSPECTIVE OF GANs and CONCLUSION

As a machine learning model, GANs are used in many smart agriculture applications such as phenotyping in plant and animal production, disease and pest detection, determination of product yield and quality characteristics, soil physical and chemical analysis and land use monitoring. However, factors such as data incompleteness, environmental variability, and uncertainties related to application factors can lead to data inconsistencies in AI-based applications. However, GANs' ability to model through data augmentation and synthetic data generation suggests that they can offer more flexible and effective solutions to overcome these challenges compared to other methods.

With technological advances in image generation, data augmentation, and deep learning-based model training, GANs hold high potential for solving agricultural problems. Indeed, researchers such as Hong et al. (2020), Saxena and Cao (2021), Abbas and Bouzid (2024), Islam et al. (2024), Zhou et al. (2024), and Murad et al. (2023) emphasize that there are many areas for future development of GANs in the agricultural sector. These areas include:

- *Increasing data quality and diversity:* High-quality and diverse datasets are crucial for GAN-based models to perform more effectively in agriculture. Future advancements in sensor technologies, remote sensing systems, and imaging devices will make data access easier, significantly improving the accuracy and generalization capacity of GANs.
- *Improving training techniques:* Problems such as mode collapse, unbalanced learning, and slow convergence that arise during training of GAN models limit their stability and performance. Therefore, the development of new optimization algorithms, the application of regularization techniques, and the support of GANs with hybrid architectures will enable the creation of more robust and efficient models.
- *Real-time applications:* While current GAN applications are largely limited to experimental applications, in the future, it will be possible to integrate these models into real-time agricultural decision support systems. For example, agricultural robots or unmanned aerial vehicles (UAVs) will be able to autonomously perform tasks such as disease detection by generating and analyzing snapshots using GANs.
- *Advanced multi-data (multimodal) models:* The need for multimodal GAN models that integrate soil, climate, plant health, imaging, and sensor data is increasing. Such holistic approaches will enable much more comprehensive and accurate assessments of crop yield predictions, environmental stress analyses, and the impacts of climate change on agriculture.
- *Integration of policy development and sustainability:* The simulation and modeling capabilities offered by GANs can enable agricultural strategies to be tested under climate

change scenarios. This will contribute to the development of sustainable agricultural policies based on scientific data and facilitate more balanced environmental, social, and economic decisions.

In conclusion, GAN-based approaches hold great promise for enhancing data diversity, improving model accuracy, and increasing the reliability of decision support systems in precision agriculture applications. However, for these technologies to be more effectively utilized within agricultural systems, there is a need for interdisciplinary collaborations, high-quality open-access datasets, and the development of application-oriented standards.

ABSTRACT

Lake Shkodra, shared between Albania and Montenegro; Lake Ohrid, located between Albania and North Macedonia; and the two Prespa Lakes, which span the borders of Albania, North Macedonia, and Greece, together form the most remarkable lake complex in Europe in terms of habitat, species, and genetic diversity. This publication presents the unique characteristics that sustain the stable and resilient condition of each lake, as well as one of their most important features - the genetic and species diversity of their fish populations. The main characteristics of Albania's large lakes should be at the center of management activities. Particularly important is the fish community, especially endemic species threatened by pollution and unregulated fishing.

Keywords: Genetic diversity, Lake Shkodra, Lake Ohrid, Prespa Lakes, species diversity.

INTRODUCTION

The hydrological complex formed by the Drin and Buna rivers, along with the natural lakes (Shkodra, Ohrid, Great Prespa, and Small Prespa), is situated on the Balkan Peninsula, within one of the regions characterised by intense tectonic, hydrographic, geomorphological, biogeographical, and evolutionary processes. This complex is part of the Adriatic Sea Basin—one of the most ecologically and scientifically intriguing areas of the Mediterranean—and belongs to the South Adriatic–Ionian zoogeographic water region, noted for its distinct features (Dhora, 2017). Although the four lakes are hydrologically interconnected and in communication with one another, each possesses unique characteristics that endow it with ecological individuality and significance.

Among the most important features of these lakes is the genetic and species diversity of their fish populations. Genetic diversity refers to the variability of genes within a species' population, while species diversity denotes the variety of species present and their relative abundance (Biba et al., 2013).

This article outlines, for each lake, the key characteristics that sustain the ecological stability and resilience of the ecosystem, as well as the genetic and species diversity of their ichthyofauna.

MATERIAL AND METHOD

The characteristics of the lakes have been primarily sourced from Dhora (2016, 2017), Dhora et al. (2016) and Group authors (2015). These characteristics have been revised and adapted according to two main aspects: the stable condition of the lakes and the genetic and species diversity of their fish. The updated fish lists for Albania's major lakes have been derived from Dhora (2020), Marić (2018), Talevski et al. (2009), Barbieri et al. (2015), and Crivelli & Catsadorakis (2012).

The discussion on species diversity was conducted by comparing data for each lake regarding the number of fish species, the number of species within the Cyprinidae family, the number of species within the Salmonidae family, the number of species migrating to the sea, the number of introduced species, and the number of endemic species.

The genetic diversity of the fish is examined based on data presented in a previous publication (Dhora, 2024), also providing several insights on *Salmo* species from the Morača River, three *Salmo* species from Lake Ohrid, *Alosa agone* Bonaparte, 1846 from Lake Shkodra, two *Rutilus* species from Lakes Shkodra and Ohrid, and on the autochthonous common carp of Lake Shkodra, which maintains genetic equilibrium (Biba et al., 2013).

RESULTS AND DISCUSSION

Below are presented the characteristics of Albania's major lakes that support the stable and resilient condition of these ecosystems, as well as the genetic and species diversity of their fish populations.

Lake Shkodra

Lake Shkodra is classified among the major lakes of the Earth (100–10,000 km²) and is the largest lake on the Balkan Peninsula in terms of surface area.

The subsiding movement of the block on which Lake Shkodra lies began at the end of the Paleogene and the beginning of the Neogene period. It is believed that this downward movement has been offset by uplift due to sediment deposition from inflowing rivers, a key geological factor contributing to the lake's long-term stability.

Karst modeling is evident in the karstic landscape, hydrographic features, lake morphology, and its high catchment potential.

Approximately 44.3% of the lake's minimum surface area lies below sea level. This feature classifies the lake as a cryptodepression—a rare phenomenon in Europe and globally. This aspect contributes to its classification as a stereotypical lake, endowing it with unique natural values, regenerative capacity, and longevity.

Lake Shkodra is a lowland lake, yet it is supplied with water from the high-altitude, high-precipitation areas of its extensive catchment basin.

The lake functions as a hydrological stabiliser. When the Drin River brings low water flow, Lake Shkodra freely discharges its waters into the Buna River. Conversely, when the Drin carries a large volume of water, it impedes the normal outflow of the Buna, thus blocking the discharge from the lake. As a result, the lake expands by increasing its water level, surface area, and volume.

Historically, Lake Shkodra has been described both as a riverine system (lotic system), where the lake was considered the potamic segment of the Morača–Buna River, and as a marsh system (lentic, palustrine) along the lowland stretch of the river. Today, Lake Shkodra represents a true lake system (lentic, lacustrine), characterised by a large, permanent water surface, distinguishing it from marshlands.

The lake's water temperature very rarely drops below 0°C, which classifies it within the subtropical thermal regime. It holds more water during the wet seasons and less in the summer months.

Lake Shkodra is marked by significant seasonal fluctuations in water level, which can reach up to 5 metres. These fluctuations are ecologically essential. During the warmer seasons and the lowering of the water level, aquatic macrophytes flourish, and biological processes such as reproduction and migration are activated.

As autumn approaches, macrophytes undergo decomposition. The decayed biomass is distributed across the lakebed sediments, while a portion is carried via the Buna River to the sea, contributing to the natural cleansing of the lake's waters.

In the colder seasons, when water levels reach their maximum, the lake undergoes a reversal in ecological dynamics. The number of habitats decreases and fauna seek shelter for overwintering.

Lake Shkodra is considered a littoral-type environment. Its shallowness and water level oscillations prevent the development of well-defined vertical zonation within the lake.

The lake is characterized by clear, oligotrophic waters with low phytoplankton biomass. The key feedback mechanisms that maintain water quality within normal parameters include: nutrient concentrations in the water versus humic production in wetlands; nutrient levels versus the productivity of riparian forest habitats; and food web structures that transfer phosphorus from littoral to pelagic zones versus biogeochemical processes that inhibit phosphorus recycling from sediments.

Lake Shkodra comprises three habitat systems: The lacustrine system, which includes limnetic and littoral habitats; The palustrine system, consisting of habitats that vary in vegetation type and the presence or absence of standing water; The riverine system, which encompasses both permanently and seasonally flooded habitats.

Aquatic macrophytes are the most characteristic feature of the littoral zone and, to a certain extent, of the entire Lake Shkodra ecosystem.

The lake is notable for its wide-ranging species diversity. It also holds significant ornithological value at a regional scale. In and around Lake Shkodra and its catchment area, a total of 283 bird species have been recorded, 168 of which are associated with aquatic habitats.

Lake Ohrid

Lake Ohrid is situated at an altitude of 693 metres above sea level, nestled between the Mokra Mountains to the west and the Galicica Mountains to the east. This lake is listed among the nine most ancient lakes selected from a group of 21 of the oldest lakes worldwide and is considered the oldest in Europe.

Lake Ohrid belongs to the group of large lakes of the globe. It has an average depth of 167 metres and a maximum depth of 288.7 metres, ranking as one of the deepest lakes in Europe—second in terms of average depth—and the largest in the Balkans by water volume. Lake Ohrid and Lake Prespa are part of the Dessaret basin group, formed by a geotectonic depression during the Pliocene epoch.

Uniquely among global lakes, Lake Ohrid is primarily spring-fed. Approximately 50% of its inflow originates from underground sources coming from Lake Prespa, which lies about 10 km to the southeast and roughly 150 metres higher in elevation. The lake has three thermal water zones. The epilimnion, the uppermost water layer, extends to about 20 metres and can reach temperatures of 24–27°C. The metalimnion lies beneath, where temperature decreases by approximately 0.5°C per metre of depth. The hypolimnion is the deepest, coldest layer, which does not receive heat from sunlight or oxygen from the atmosphere. At 150 metres depth, the temperature is about 6°C.

The open waters of Lake Ohrid are oligotrophic, whereas the nearshore zones are considered mesotrophic.

Lake Ohrid is characterised by outstanding biodiversity, including: Habitat diversity, often physically and/or ecologically isolated; Species diversity, particularly of endemic taxa; Genetic diversity in several biological groups. The lake's biota exhibits strong resistance to biological invasion, not only due to its physical isolation from surrounding waters but also because its biocenosis is homogeneous, stable, and a product of long-term evolutionary processes.

Lake Ohrid holds the highest density of endemic species per surface area of any lake in the world. The presence of cold, oxygen-rich underwater springs, combined with both horizontal and vertical isolation, are the main drivers of the lake's unique evolutionary pathways, its high level of endemism, and its ecological stability.

Lake Ohrid is often described as a “museum of relict species” or a “repository of living fossils,” as many species that were once widespread millions of years ago and are now extinct elsewhere have survived only in this lake. The most notable relict groups include Diatoms, Gastropods, and Salmonids, with the benthic community being among the most interesting.

Zooplankton plays a vital role in the lake's food web, serving as the primary food source for smaller fish, which in turn sustain predatory fish, including trout. A total of 270 bird species have been recorded in Lake Ohrid and its surrounding catchment.

The Prespa Lakes

The Prespa Lakes—Great Prespa Lake and Small Prespa Lake — form part of the Dessaret basin group, which originated from a geotectonic depression during the Pliocene epoch. Great Prespa Lake is included in the list of the 21 oldest lakes in the world. Located at altitudes ranging from 844 to 852 metres above sea level, they are considered the highest tectonic lakes in the Balkans.

Great Prespa Lake

Great Prespa Lake belongs to the group of large global lakes (100 – 10,000 km²). It receives water primarily through **surface inflows**, while its outflows are subterranean, passing through the karstic systems beneath **Mount Galicica** and **Mount Mali i Thate**, and emerging as springs in **Tushemisht** and **Saint Naum**, which subsequently feed **Lake Ohrid**.

The lake has a **maximum depth of 52 metres**. Over the past few decades, the water level has dropped by approximately **8 metres**, likely due to changes in the underground karstic water flow, or possibly for other **natural or anthropogenic reasons**. Unlike Lake Ohrid, **thermal stratification** in Great Prespa Lake is **less distinct**, although a general layering does exist. For the majority of the year, the **open waters** of Great Prespa exhibit **oligotrophic** characteristics, shifting towards **mesotrophic conditions** during the summer months.

Ecological stability in Great Prespa Lake is attributed to its **clean waters** and a **dual scheme of primary production**, supported by two key components of the ecosystem: **phytoplankton**, which thrives in the surface thermal layer, and **rooted macrophytes** in the littoral zone.

Small Prespa Lake

Small Prespa Lake is **shallow**, with a **maximum depth of only 7.7 metres**, and exhibits **eutrophic conditions** due to higher levels of **phosphorus concentration**. It is rich in emergent vegetation and wetland habitats, making it ecologically significant, especially for birdlife.

Landscape and biodiversity

The lakes are surrounded by **diverse habitats**, scenic **bays**, and **remarkable islands** such as **Golem Grad**, **Maligrad**, **Agios Achillios**, and **Vidronisi**, which, together with the **pristine nature** and **clear waters**, contribute to the lakes' **aesthetic and ecological value**. The **habitat diversity**,

species richness, and **presence of endemic taxa**—particularly among **gastropods** and **fish**—highlight the lakes' **conservation priority** status. In total, **over 200 bird species** have been recorded in the Prespa Lakes. In recent decades, the **wintering waterbird populations** have reached up to **50,000 individuals**.

In terms of **biogeographical classification**, Great Prespa Lake is generally grouped within the **Adriatic–Ionian Lake system**, which also includes **Lake Ohrid**. However, it can also be considered **ecologically distinct** from Lake Ohrid and the broader **Eastern Lake Group**, which comprises two Balkan and three Anatolian lakes. To date, **28 species of aquatic macrophytes** have been recorded in Great Prespa Lake. **Over 200 bird species** have been recorded in the two Prespa Lakes. In the past two decades, the **maximum number of waterbird individuals** counted during the winter period has approached **50,000**.

On the genetic diversity of fish

The species *Salmo obtusirostris* Heckel, 1851 is considered a complex species. This group includes *Salmo zetensis* Karaman, 1938 from the Zeta River, which some authors regard as a subspecies of *S. obtusirostris*. Two other species, *Salmo montenigrinus* Karaman, 1933 from the Morača River, considered by some authors as a synonym of *S. obtusirostris*, and *Salmo taleri* Karaman, 1933 from the upper course of the Zeta River, morphologically resembling *S. cf. farioides* Karaman, 1938 have so far been recorded only at a single locality. Therefore, the *Salmo* species of the Morača River basin, which includes the Zeta and Cem tributaries, are still not well known, although six *Salmo* species are reported. It is necessary to deepen research to accurately determine these species or subspecies, including the use of genetic analyses.

A thorough study is required on the non-migratory *Alosa agone* population of Lake Shkodra. This study should also investigate whether migration to the sea occurs, and gradually reveal further relevant data. For years, a portion of individuals older than three years may not have participated in migration to the sea. Over time, a non-migratory population may have formed, adapted to life along the northeastern shore of the Albanian part of the lake, and possibly reproducing there as well. Individuals of this population are smaller than migratory ones, have shorter heads, and fewer spots on both sides of the body (Kottelat & Freyhof 2007). This long-established population is *Alosa agone*, living in sympatry with *Alosa fallax* Lacépède, 1803 (Rakaj & Crivelli, 2001). These findings were also discussed in a previously published article (Dhora, 2024).

In Albania, the common carp (*Cyprinus carpio* Linnaeus, 1758) was introduced by the Romans, who cultivated it. Considering its adaptive capacity, the carp population in Lake Shkoder can be regarded as an autochthonous species of the lake. Microsatellites have been used as molecular markers to assess genetic variability at the DNA level in carp populations of Lake Shkodra and Lake Ohrid. This study found that only the carp population of Lake Shkodra, at the MFW6 locus, is in genetic equilibrium (Biba et al., 2013). The conservation of the native common carp in Lake Ohrid, and possibly also in the Prespa Lakes, should be ensured through careful stock enhancement based on selected individuals, using controlled technology.

Rutilus karamani Fowler, 1977 and *Rutilus ohridanus* Karaman, 1924, previously considered distinct species in Lake Shkodra, are regarded by Bianco & Ketmaier (2014) as synonyms of a single species, *Leucos basak* Heckel, 1843. They were once classified as subspecies: *karamani* as the yellow roach and *ohridanus* as the white roach (Dhora et al., 2008). In the publication of Dhora (2024), it is suggested that this variation may represent intraspecific diversity, possibly as colour morphs related to the characteristics of their aquatic habitats and their adaptive abilities.

Equally important is the study of trout in general, and particularly the species of Lake Ohrid: *Salmo aphelios* Kottelat, 1997; *Salmo balcanicus* Karaman, 1927; *Salmo lumi* Poljakov, Filipi &

Basho, 1958, and *Salmo ohridanus* Steindachner, 1892. In many cases, trout populations are on the brink of collapse due to pollution, declining water levels, and unregulated fishing.

On the species diversity of fish

The list of freshwater fish species in Albania, according to Dhora (2020), comprises 100 species. The two most significant families in terms of species number are Cyprinidae with 40 species and Salmonidae with 15 species.

The Table 1 below provides, for each lake, the following data: the number of fish species, the number of species from the Cyprinidae family, the number of species from the Salmonidae family, the number of migratory species to the sea, the number of introduced species, and the number of endemic species.

Table 1

Lakes	Species number	Cyprinidae	Salmonidae	Migratory to the sea	Introduced	Endemic
Lake Shkodra	45	26	7	8	16	6
Lake Ohrid	28	15	6	2	4	5
Great Prespa lake	30	19	3	1	14	7
Small Prespa lake	18	14	?	1	8	7

As shown in the table, Lake Shkodra has the highest number of fish species with 45, followed by Great Prespa Lake with 30 species, then Lake Ohrid with 28 species, and finally Small Prespa Lake with 18 species.

The number of species in the family Cyprinidae is as follows: Lake Shkodra has 26 species, Great Prespa Lake 19 species, Lake Ohrid 15 species, and Small Prespa Lake 14 species. The total number of species and those of the Cyprinidae family is greatest in Lake Shkodra due to its subtropical characteristics, large surface area, and shallow depth over most of its extent. After Lake Shkodra, Great Prespa Lake follows with a considerable difference in both total species and Cyprinidae species. This is because it is shallower and more eutrophic, especially along the gently sloping shores with abundant vegetation. The difference becomes more pronounced in the other lakes.

Lake Shkodra also has the greatest number of species from the family Salmonidae, as this count includes the trout of the Morača River, which flows into the lake and contributes over 60% of the lake's total water inflow. Lake Ohrid has deep waters sourced from both surface and subterranean springs, which are well suited to salmonids.

Due to its close proximity and connection to the Adriatic Sea via the Buna River, Lake Shkodra also hosts numerous migratory species that move to the sea.

Both Lake Shkodra and Large Prespa Lake have many introduced species, numbering 16 and 14 respectively. Many of these species were introduced to increase fish production for consumption. By contrast, Lake Ohrid has 4 introduced species, while Small Prespa Lake has 8. The latter is a shallow and eutrophic lake.

Each lake hosts endemic species. The endemic species of the two Prespa lakes are almost identical due to their close hydrological connection. Lake Shkodra shares some endemic species with the Morača River. Meanwhile, Lake Ohrid's endemic species have developed within the lake itself, primarily due to geographical and ecological isolation.

CONCLUSIONS

Many of the most prominent values of the lakes are considered unique. Lake Shkodra, for instance, is a rare cryptodepression in Europe and worldwide. Lake Ohrid is unique globally because it is primarily fed by springs and ranks as the richest lake in endemic species relative to its surface area on the entire planet. The Prespa Lakes, situated at an altitude of 852 metres, are the highest lakes in the Balkans. Water entering these lakes through surface flow disappears beneath Mount Galicica and Mount Thate, re-emerging as springs at Tushemisht and Saint Naum, which feed Lake Ohrid.

The main characteristics of Albania's large lakes should be at the centre of management activities. Particularly important is the fish community, especially endemic species threatened by pollution and unregulated fishing.

Care must be taken to recognise the high genetic and species diversity of the fish populations in these lakes. The three endemic trout species of Lake Ohrid need to be confirmed as distinct species through genetic analyses. For the six trout species in the Morača River, genetic studies are necessary to differentiate species and subspecies. A comprehensive study of the non-migratory *Alosa* population in Lake Shkodra is required, including morphological, genetic, embryological, ecological, and evolutionary analyses. *Rutilus karamani* and *Rutilus ohridanus* have been unified into one species; however, further wider population and genetic studies are needed in both Lake Shkodra and Lake Ohrid to clarify whether these represent subspecies or distinct forms.

Lake Shkodra, Lake Ohrid, and the Prespa Lakes have been declared protected areas by their respective countries. In the future, it is envisaged that the entire hydrological complex and its catchment basin should be declared a protected area, which would involve five countries in an integrated and much more successful management effort.

ACKNOWLEDGEMENTS

I would like to express my sincere gratitude to the University of Shkodra "Luigj Gurakuqi" for the financial support provided for the publication of this article. This support was instrumental in enabling the dissemination of our research titled "*Genetic and Species Diversity of Fish in Albania's Major Lakes*". I greatly appreciate the University's continued commitment to fostering scientific research and academic development.

ABSTRACT

The aim of this study was to determine the effect of intercropping maize and beans on changes in chlorophyll content and yield. Plots were set up with two maize seeds followed by one bean seed in a row. Four irrigation levels were applied to the plants. The control treatment (S100) was defined as the treatment where the plants' water requirements were supplied in entirety. The treatments with 20% (S80), 40% (S60), and 60% (S40) water deficits were defined as the deficit irrigation treatments. The chlorophyll content values of the plants were as follows: in maize, S100: 50.85, S80: 49.85, S60: 48.10, S40: 46.35; while in beans, it was measured as S100: 39.95, S80: 40.80, S60: 38.70, S40: 38.30. The highest chlorophyll content was determined in maize for S100 and in beans for S80. The average total green forage yield was determined as S100: 9951, S80: 9102, S60: 8325, S40: 7927 kg da⁻¹.

Keywords: intercropping, deficit irrigation, forage yield, evapotranspiration

INTRODUCTION

The effects of climate change around the world have made the proper management of natural resources, especially water, a priority. Irregular rainfall, the depletion of drinking and irrigation water sources, and environmental problems caused by industrialization make careful use of water essential. With the growing population, the need for water is increasing at the same rate; this demand is becoming more pronounced in both daily life and production. Under these conditions, the amount of water used in agriculture is decreasing, and the conscious use of water is becoming increasingly important. Water conservation is not only an environmental responsibility but has also become a fundamental part of economic development and social welfare. Therefore, the conservation and efficient use of water resources is now an inevitable necessity.

The continuity of agricultural production must be ensured in order to meet the increasing demand for food. The balanced and efficient use of water resources is vital for the sustainability of this production. Success in water management increases agricultural yield on the one hand and reduces the environmental burden on the other. In particular, the adoption of modern irrigation methods and the application of techniques for the economical use of water will increase efficiency in agricultural production while also contributing to the sustainability of water resources.

In recent years, the decline in water resources and the corresponding increase in water demand have brought to the forefront the concept of producing more with less water in agricultural production. The methods developed in this context aim to adapt production to these new conditions by focusing on saving water. Deficit irrigation systems and intercropping techniques, which aim to maintain yields with limited water, are notable effective applications in this regard. Thanks to these methods, continuity in production can be ensured even with scarce water resources.

Intercropping also offers various advantages against harmful insects and diseases. Having different plants in the same area makes it difficult for pests to target a single species, thereby limiting the spread of disease and protecting production (Altieri, 2018). This reduces the need for chemical pesticides and creates an environmentally friendly production model.

Beans preserve soil fertility with their nitrogen-fixing properties, while maize contributes to moisture balance by utilizing groundwater thanks to its deep roots (Frankenberger et al., 2002). This synergy enables more efficient use of both water and nutrients, thereby improving product quality and preserving the balance of the agricultural ecosystem. Li et al. (2023) conducted a study to investigate the effects of soil interactions in maize-pea intercropping systems on crop yield and nutrient uptake. This research, conducted between 2017 and 2020, utilized field and pot experiments. The findings showed that intercropping increased the yield of both species. For example, in 2018, fava bean yield increased by 4.19%, while maize yield increased by 6.01%. In terms of nutrient accumulation, it was determined that nitrogen and phosphorus uptake in fava beans increased significantly in intercropping systems.

In conclusion, intercropping complementary crops such as silage maize and beans increases agricultural productivity, offers an environmentally friendly production model, and contributes to the sustainable use of natural resources. Therefore, the widespread adoption of intercropping methods is of strategic importance for the success of future agricultural policies.

The aim of this study is to determine the yield, leaf area index (YAI), and chlorophyll content obtained from the intercropping system by applying different levels of irrigation water to maize and beans intercropped together.

MATERIAL AND METHOD

Material

This study was conducted on land belonging to the Eastern Mediterranean Transition Zone Agricultural Research Institute (DAGTEM) located in the province of Kahramanmaraş. The study area is 465 meters above sea level and is located between 37°55'08" north latitude and 36°55'09" east longitude. In September and October of both years, a significant decrease in minimum temperatures was observed. Temperatures of 8.6 °C were recorded in October 2022 and 9.5 °C in October 2023. These temperatures are at levels that could cause cold stress in some plants during their late stages of development.

When evaluating precipitation data, 2022 was a notable period in terms of drought. Precipitation amounts were quite low in July and September. The year 2023 stood out with higher rainfall values; 16.4 mm of rainfall was recorded in June and 17.7 mm in July. These values are above the long-term average for the period 1960–2021. This indicates that soil moisture was naturally supported, especially during the 2023 season.

When examining the physical properties of the soil in the study area, it is observed that the bulk density values range between 1.54–1.64 g cm⁻³. These values indicate a medium texture and a structure favorable for plant root development. The field capacity determined on a weight basis varies between 21.4% and 23.5%, while the wilting point varies between 12.2% and 14.3%. Based on these parameters, calculations show that for the 0–90 cm soil profile, the field capacity (FC) is 327.8 mm, the wilting point (WP) is 189.3 mm, and the available water holding capacity (AWHC) is 138.6 mm (Keten, 2020).

In this study, two field crop varieties adapted to the region's climatic and soil characteristics were selected. The varieties named “Colonia” for silage maize and “Bulduk” for beans were preferred. Both types stand out for their fundamental agricultural characteristics, such as high yield potential and

tolerance to environmental stresses. The Colonia maize and Bulduk dry bean varieties used in the study offer significant advantages in agricultural production due to their high yields, environmental tolerance, and nutritional value. Thanks to these characteristics, they provide both economic returns and contribute to sustainable agricultural systems.

Method

The intercropping method used in the study has been evaluated as an important strategy for increasing agricultural productivity and more effective use of resources. In this system, maize and beans were grown together in the same field plot and in the same row. The plants were arranged in a “2M:1F” pattern; that is, one bean plant was added after every two maize plants. Maize plants were planted 15 cm apart in the row, while bean plants were planted approximately 30 cm apart.

This structure provided an environment that preserved the maize's dominant vertical growth advantage while also providing shade and support for the beans to climb. Based on the planting pattern obtained, plant densities were calculated to be 9,524 plants/da for maize and 4,762 plants/da for beans. These values reflect the population level necessary for both species to thrive in the same environment. When maize and beans are planted together, they exhibit complementary structural and functional characteristics. The sturdy and upright stem structure of maize supports beans, facilitating their vertical growth; while the bean plant fixes atmospheric nitrogen into the soil, contributing to the natural fulfillment of maize's nitrogen requirements (Kumar et al., 2019).

In this study, different irrigation topics were determined to identify the most appropriate water restriction percentage to maintain silage yield. Four different irrigation topics were planned in this experiment, and these topics were planned and implemented as described below:

S100 (Full irrigation level): The entire amount of water required to reach field capacity (100%) was applied. This is the control treatment. S80 (Deficit irrigation): Water was reduced by 20% from the control treatment level, and 80% of the control treatment level was applied.

S60 (Deficit irrigation): Water was reduced by 40% from the control treatment level, and 60% of the control treatment level was applied.

S40 (Deficit irrigation): Water was reduced by 60% from the control level, providing 40% of the control level.

The trial studies were conducted on plots, each 7 m long and 3.5 m wide, with a total area of 35 m². A distance of 2 m was left between plots and 3 m between blocks. This layout was chosen to prevent the different applications from affecting each other.

Within the scope of the research, two different plant species, silage maize (M) and beans (F), were planted together using the intercropping method. Four different irrigation treatments (100%, 80%, 60%, 40%) were applied to these plants, allowing for a systematic analysis of the effects of water deficiency on plant growth, physiological indicators, and yield. Each treatment was applied in a randomized block design with three replications. This established an experimental design that was both scientifically valid and field-applicable (Figure 1).

Figure 1. Schematic diagram of the trial design

Chlorophyll content, one of the important indicators of plant physiology, is a fundamental parameter reflecting photosynthetic capacity and overall metabolic status. In this study, chlorophyll density was measured using the SPAD device, a non-destructive and rapid method.

The SPAD-502 Plus (Konica Minolta, Japan) model device measures how much light the leaf absorbs by emitting light at red and infrared wavelengths onto the leaf surface, reflecting chlorophyll content as an index value (Uddling et al., 2007). The advantage of this device is that it is fast, portable, and can take measurements without damaging the leaf.

Measurements were taken before and after irrigation throughout the plant growth period. In each plot, measurements were taken at five separate points selected from middle-aged leaves, the device was placed perpendicular to the leaf, and care was taken to avoid shadows. The average of the obtained values was taken and used in the analyses.

Due to the high correlation between the SPAD value and the nitrogen content in the leaf, this method is also considered an indirect tool for monitoring plant nutrition (Chang et al., 2003). A decrease in the SPAD value under stress conditions, such as irrigation restriction, reveals the plant's physiological response to water.

The LAI is a dimensionless measure that indicates the total leaf area per unit of soil area. It is considered one of the fundamental indicators for assessing a plant's photosynthetic capacity, how

effectively it utilizes sunlight, and for monitoring processes such as water loss through transpiration (Watson, 1974; Jonckheere et al., 2004). LAI is also widely used to track changes in plant development over time, analyze responses to stress conditions such as drought, and evaluate the effects of applied agricultural methods.

In this study, LAI measurements were performed using the AccuPAR LP-80 model device, which operates based on light transmittance. This device indirectly calculates leaf density by simultaneously measuring sunlight intensity from the upper and lower parts of the leaf canopy (Norman et al., 1989). These measurements provide information about the light interception rate and leaf distribution of the plant canopy.

In practice, measurements were taken in two separate periods, before and after irrigation, in each plot to evaluate the effect of irrigation. In each measurement, lower and upper readings were taken from five different points within the plot as recommended by the device, and the leaf area index for that plot was determined using the average of these measurements.

Leaf area index measurements have been an important assessment tool for revealing the density of plant cover and the effect of agricultural practices on leaf development.

RESULTS AND DISCUSSION

Determination of chlorophyll content

In the study, the leaf chlorophyll content of silage maize and bean plants was determined using the SPAD-502 portable measurement device. Measurements were taken at regular intervals before and after each irrigation throughout the production period. Measurements for the first year (2022) began on August 10, and measurements for the second year (2023) began on August 20. Graphs of these values are provided in Figures 2, 3, 4, and 5.

Figure 2. Chlorophyll meter values for maize in 2022

Figure 3. Chlorophyll meter values for maize in 2023

Figure 4. Chlorophyll meter values for bean in 2022

Figure 5. Chlorophyll meter values for beans in 2023

The chlorophyll content values obtained in this study were determined as an average of 50.3 for the maize plant in the S100 application in 2022 and 50.4 in 2023; it was observed that these values gradually decreased at reduced irrigation levels. The lowest average value was recorded at 42.4 in the S40 application in 2023. In the bean plant, the S100 average was 40.0 in 2022 and 39.9 in 2023; the lowest values were again determined in the S60 and S40 applications, where water restriction was intense. These data reveal that chlorophyll content is higher in full irrigation applications and that chlorophyll synthesis is suppressed due to water stress associated with restricted irrigation.

Leaf Area Index (LAI) measurements were taken at regular intervals over two growing seasons. Measurements began one day before irrigation started and were repeated before and after irrigation throughout the irrigation period. Graphs of the measured leaf area index values are shown in Figure 6 and Figure 7.

Figure 6. Leaf area index (LAI) values for 2022

Figure 7. Leaf area index (LAI) values for 2023

-Measurements taken throughout the 2022 production season determined that the average YAI value was $3.06 \text{ m}^2 \text{ m}^{-2}$ for the S100 application, $3.26 \text{ m}^2 \text{ m}^{-2}$ for S80, $2.91 \text{ m}^2 \text{ m}^{-2}$ for S60, and $2.67 \text{ m}^2 \text{ m}^{-2}$ for S40. The value of $4.69 \text{ m}^2 \text{ m}^{-2}$ obtained in the sixth irrigation period on the S60 plot in the same year is the highest LAI value among all measurements. The lowest value was recorded in the first irrigation period on the S60 plot, at $2.21 \text{ m}^2 \text{ m}^{-2}$. The average leaf area index (LAI) values for

2022 ranged between 2.67 and 3.26 m² m⁻². YAI data for the 2023 production year was higher than in 2022. Average LAI values were measured as 4.10 m² m⁻² in S100, 3.87 m² m⁻² in S80, 3.12 m² m⁻² in S60, and 3.50 m² m⁻² in S40. The highest value was 5.32 m² m⁻², recorded in the fifth irrigation period on the S100 plot. This suggests that the second year was more favorable in terms of plant development. The average leaf area index (LAI) values for 2023 ranged from 3.12 to 4.10 m² m⁻². The LAI values obtained show that successful results can be achieved with the intercropping system under the environmental conditions specific to Turkey's semi-arid transition zone. In particular, the value of 4.10 m² m⁻² achieved in 2023 indicates a leaf density close to maximum light interception capacity. This result reveals that the applied 2M:1F row pattern provides an optimal growth environment for both maize and beans by balancing light and space competition between species. Plant canopy density increased due to the effect of the planting pattern.

The YAI levels determined in the study showed a high degree of consistency with data reported in the literature, such as Çiftçi et al. (2006), Arıkan and Yılmaz (2008), and Cammarano et al. (2023). However, it is thought that the much higher YAI values reported in studies such as Iqbal et al. (2006) and Shah et al. (2022) were obtained due to the different physiological structure of the species used (e.g., cowpea, soybean) and higher plant density.

In 2022, the average green forage yield was determined to be 9240 kg ha⁻¹. This value was found to be 9088 kg ha⁻¹ in the S80 plot, 8905 kg ha⁻¹ in S60, and 8455 kg ha⁻¹ in S40. The highest green forage yield was obtained from the S100 application, at 10,621 kg da⁻¹.

In the 2023 growing season, the total green forage yield was generally lower. The average yield was calculated as 8365 kg da⁻¹, with the highest yield value of 9282 kg da⁻¹ obtained from the S100 plot. Yields of 9116 and 7552 kg da⁻¹ were obtained in the S80 and S60 applications, respectively, while the lowest value of 7509 kg da⁻¹ was observed in the S40 treatment. Table 1 shows the total green forage yield (kg ha⁻¹) values and Duncan groups for different irrigation levels by year.

Table 1. The total green forage yield of varieties

Year	Total green forage yield kg da ⁻¹				
	S100	S80	S60	S40	Average
2022	10621a	9088b	8905b	8345b	9240a
2023	9282b	9116b	7552b	7509b	8365b
2022-2023	9951a	9102ab	8228b	7927b	8802

When evaluated based on the two-year averages, the total green forage yield ranged between 7927 and 9951 kg ha⁻¹. The highest average yield of 9951 kg ha⁻¹ was obtained with the full irrigation (S100) treatment. This treatment was followed by S80 (9102 kg da⁻¹), S60 (8325 kg da⁻¹), and S40 (7927 kg da⁻¹), respectively. Based on the two-year averages, S100 was in the a letter group and provided statistically significantly higher yields than all other irrigation levels. The S80 treatment was in the abc letter groups and was not statistically distinct from the S100 treatment. The S60 treatment was in the c–f letter group and showed medium yield. The S40 treatment was in the d–g group and was statistically close to the lowest yield group.

These findings show that full irrigation conditions (S100) provide maximum yield in green forage production, while water restrictions statistically limit yield, especially at levels of 60% and below. It is understood that as the irrigation level increases, plant growth is encouraged and, consequently, green forage production increases.

In studies conducted on intercropping systems, the total green forage yield values for silage maize and legumes were as follows: Şimşek et al. (2005), under Turkey-Harran Plain conditions, in a 2M:1S (maize + soybean) strip intercropping system, 4800–5700 kg ha⁻¹; Kızıl Aydemir (2018), under Turkey-Iğdır conditions, in an M+70%S mixture, 9410–10280.1 kg ha⁻¹ was found.

CONCLUSION

This study presents important findings demonstrating the effectiveness of intercropping systems, particularly in semi-arid regions. Intercropping silage maize and beans in a 2M:1F row pattern yields extremely efficient results in terms of both biomass production and water use efficiency. In particular, the fact that the S80 irrigation level provides significant water savings while maintaining yield levels with an acceptable loss of 8–10% makes it necessary to recommend it as an effective strategy for the sustainable use of water resources.

One of the most noteworthy findings of the study, chlorophyll content, is recommended to be used as a direct indicator in the evaluation of irrigation levels, in line with its close relationship with the plant's access to water. The high chlorophyll values remaining in the S100 and S80 applications indicate that the plants did not enter physiological water stress, proving that the S80 level, in particular, can provide maximum physiological performance with minimum water use compared to the S100 irrigation level.

In conclusion, based on the data presented in this study, the integration of dual cropping in a 2M:1F pattern, restricted irrigation at the S80 level, and chlorophyll content measurements into agricultural decision-making processes is among the main strategies recommended for achieving high yields and efficient resource management in semi-arid regions.

ABSTRACT

Weeds are among the most significant biological agents in many agricultural systems, and have an adverse impact not only on crop yield but also on crop quality. Although chemical weed control is recommended only as a complementary component of integrated weed management, it remains widely used by growers for its rapid efficacy, despite off-target risks such as spray drift. Non-selective herbicides applied in orchards or non-agricultural fields to control weeds may move from the applied fields to adjacent agricultural fields, sometimes the fields that were grown with medicinal and aromatic crops such as fennel (*Foeniculum vulgare* Mill.). This study was conducted to determine the adverse impacts of sub-lethal rates (12.5%, 6.25%, 3.125%, and 1% of the recommended rates) of glyphosate isopropylamine salt (1440 g ai ha⁻¹) and flazasulfuron (50 g ai ha⁻¹) under climate room conditions. Herbicides were applied to fennel seedlings when they reached 2-4 true leaves, and they were placed in a climate room adjusted to 16h/8h photoperiod, 24/20°C (day/night) temperature. The impact of the herbicides on fennel seedlings was evaluated 21 days after treatment. Glyphosate and flazasulfuron reduced fennel dry biomass by up to 53% and 62.7% in a rate-dependent manner, respectively.

Keywords: Glyphosate, flazasulfuron, fennel, *Foeniculum vulgare*, drift

INTRODUCTION

Fennel (*Foeniculum vulgare* Mill.) represents a commercially significant perennial herb within the Apiaceae family. The species is distinguished by its characteristic production of anise-flavored volatile compounds and its versatile applications spanning the culinary, pharmaceutical, and agrochemical industries (Rather et al., 2016). Native to the Mediterranean region, fennel has been cultivated for centuries and has spread globally due to its economic importance. The plant's aromatic properties are attributed to its essential oils, primarily composed of compounds like trans-anethole, fenchone, α -phellandrene, and estragole, which collectively dictate its characteristic flavor and contribute to its recognized medicinal and aromatic properties (Díaz-Maroto et al., 2006). These volatile compounds not only contribute to fennel's distinctive flavor and fragrance but also possess various biological activities, making it a valuable resource for natural product research and development. These properties have led to increased interest in fennel as a potential source of natural preservatives and therapeutic agents in the food and pharmaceutical industries (Jadid et al., 2023). Furthermore, the plant's adaptability to various climates and its relatively low maintenance requirements have contributed to its widespread cultivation, making it an economically important crop in many regions worldwide.

While fennel holds considerable economic value, its cultivation is vulnerable to certain abiotic stressors, such as herbicide drift, which can substantially reduce yields and compromise the quality of the harvested product. Therefore, it is essential to investigate the non-target effects of sub-lethal herbicide concentrations on fennel's early growth patterns, particularly considering the widespread use of glyphosate and flazasulfuron. Glyphosate, a widely used non-selective herbicide, exerts its phytotoxic effects by disrupting the shikimate pathway, a crucial metabolic route in plants responsible for the synthesis of essential aromatic amino acids like phenylalanine, tyrosine, and tryptophan. Flazasulfuron, in contrast, inhibits plant growth by targeting acetolactate synthase, an enzyme pivotal in the synthesis of branched-chain amino acids such as valine, leucine, and isoleucine, consequently disrupting protein production and overall plant metabolism.

Impact of sub-lethal glyphosate rates on non-target crops varies depending on the crop species, environmental conditions, and application timing; these factors may initiate a complex cascade of physiological and morphological alterations. For instance, plants exposed to sub-lethal rates of glyphosate may exhibit reduced photosynthetic efficiency, impaired nutrient uptake, and altered carbon allocation patterns, ultimately leading to stunted growth and reduced yields. Brown et al. (2009) showed glyphosate drift rates significantly reduced corn height and shoot dry biomass up to 45% and 46%, respectively, depending on the rate. Moreover, if this drift occurs before in-crop herbicide application, the adverse impact of glyphosate drift is more destructive than alone. Similarly, sub-lethal rates of ALS/AHAS inhibitor herbicides can trigger a range of responses in non-target plants, including stunted growth, chlorosis, and altered reproductive development, potentially leading to yield reductions and diminished product quality. Bailey and Kapusta (1993) indicated that soybean plants subjected to sub-lethal exposures of nicosulfuron and primisulfuron exhibited reduced shoot growth and developed leaf cupping, leaf chlorosis, and leaf necrosis. Although numerous studies have been conducted on the impact of glyphosate and ALS/AHAS inhibitors on major crops, there is currently limited information available about the physiological responses of fennel to sub-lethal concentrations of glyphosate and flazasulfuron. Because of these gaps in knowledge, we measured how fennel responded to sub-lethal levels of glyphosate and flazasulfuron in a controlled setting, looking at visual injury, height, and biomass as outcomes.

The study was conducted to determine the physiological impacts of sub-lethal rates of glyphosate and flazasulfuron on fennel seedlings in climate room conditions.

MATERIAL AND METHOD

A dose-response study was conducted in a climate room adjusted to 24 ± 1 °C/ 20 ± 1 °C with a 16/8 h day/night photoperiod to determine the response of fennel to sub-lethal rates of glyphosate isopropylamin salt (Forfosat 48 SL; Koruma Klor Corporation, Kocaeli, Turkey) and flazasulfuron (Coswel 250 WG; Adama Corporation, Izmir, Turkey). The climate room was set light to LED lamps (10 W). Five fennel seeds were sown in plastic pots ($7 \times 7 \times 8.5$ cm) filled with white peat bedding substrate + white perlite (4/1 w/w). After emergence seedlings were removed so that only two plants remained per pot. The seedlings were irrigated using tap water as needed.

Sub-lethal rates (12.5%, 6.25%, 3.125%, 1% of the recommended rates) of Glyphosate (1440 g ai ha⁻¹) and flazasulfuron (50 g ai ha⁻¹) were dissolved in deionized water without any surfactant to simulate drift conditions. These rates were applied using a sprayer equipped with an even flat-fan nozzle mounted (Teejet EVS11001) at the 2-4 true leaf stage. Sprayer was calibrated to deliver 195 L ha⁻¹. Untreated control was included. The impact of the rates of the herbicides on fennel seedlings was evaluated 21 days after treatment (DAT). Herbicide efficacy on the fennel seedlings was visually

evaluated using a 0-100 scale, 0 indicated control plants, whereas 100 indicated dead plants. The height of the seedlings was measured from the soil surface to the top of them at 21 DAT, and they were cut from ground level. The seedlings were placed in a drying oven at 60 °C for 48 h to determine the above ground dry weight.

Treatments were arranged in a completely randomized design with four replications per treatment, and the experiment was repeated twice over time. The data were subjected to variance analysis using the Agricolae package (Mendiburu & Yaseen, 2020) in R statistical software (R Studio Team, 2024). The means were compared using the Least Significant Difference test at the 5% probability level.

RESULTS AND DISCUSSION

Glyphosate rates resulted in a statistically significant, dose-dependent increase in the severity of visual injury observed on fennel seedlings, where high glyphosate rates (above 45.13 g ai ha⁻¹) resulted in a statistically significant difference compared to the untreated control, whereas the lowest rate (14.44 g ai ha⁻¹) did not (Figure 1). Similar to the observations with glyphosate, flazasulfuron application also elicited a statistically significant and dose-responsive increase in the visual injury scores of fennel seedlings, except for the lowest rate (0.50 g ai ha⁻¹) (Figure 2). However, observed visual injury in fennel seedlings applied at the rates of 6.25% and 3.125% of the recommended rates of flazasulfuron was higher than that observed in fennel seedlings applied at the rates of 12.5% and 6.25% of the recommended rates of glyphosate. These results confirmed flazasulfuron's phytotoxic effect on fennel even when applied at low rates.

Figure 1. Response of fennel to glyphosate isopropylamine salt rates at the climate-room pot experiment.

Figure 2. Response of fennel to flazasulfuron rates at the climate-room pot experiment.

Plant height exhibited a significant reduction in response to increasing rates of both glyphosate and flazasulfuron, which is consistent with visual injury data (Table 1). Specifically, the application of flazasulfuron resulted in a more evident reduction in plant height compared to the application of glyphosate due to greater impact on the early vegetative development of fennel seedlings. Unlike dry biomass results, the lowest rates of both herbicides could not result in a significant height reduction compared to the control treatment. Consistent with the observed reductions in plant height, the above-ground dry weight of fennel seedlings exhibited a similar trend for both herbicides (Table 1). Increasing rates of them caused a decline in biomass accumulation, suggesting a direct impact of herbicide exposure.

Table 1. Response of fennel seedlings to sub-lethal rates of glyphosate isopropylamine salt and flazasulfuron in the climate room experiment

Herbicide	Rate (g ai ha ⁻¹)	Dry biomass (mg)	Height (mm)	Visual Injury (%)
Glyphosate isopropylamine salt	0	44.88 (5.87) a*	178.88 (7.20) a	-
	14.44	40.75 (2.79) a	175.75 (7.56) a	3.75
	45.13	35.25 (3.57) ab	148.13 (11.95) ab	16.25
	90.25	22.25 (1.81) bc	119.75 (6.32) bc	28.75
	180.50	21.00 (1.77) c	104.25 (10.05) c	45
Flazasulfuron	0	55.25 (7.73) a	135.13 (3.15) a	-
	0.50	49.50 (5.08) ab	139.38 (11.58) a	5
	1.56	32.50 (1.73) bc	134.75 (5.88) a	17.5
	3.13	22.75 (2.50) c	76.00 (7.51) b	31.25

	6.25	20.63 (1.92) c	70.88 (4.39) b	50

*Within each herbicide, means followed by different letters are significantly different at $P \leq 0.05$ (LSD).

Sub-lethal rates of glyphosate negatively affected fennel growth, similar to other susceptible crops, such as sunflower, soybean, wheat, and tomato, despite these plants exhibiting varying sensitivities to it. Sunflowers exposed to a rate of 86.4 g a.e ha⁻¹ of glyphosate resulted in a 55% height reduction and a 50.47% decline in the number of leaves per plant (Vital et al., 2017), whereas soybeans exposed to a higher glyphosate rate, such as 140 g ai ha⁻¹, showed less sensitivity to glyphosate (Ellis and Griffin, 2002). Roider et al., (2007) indicated that glyphosate applied at a 140 g ai ha⁻¹ reduced wheat height up to 36% 14 DAT while causing an injury up to 61% 28 DAT. Tomato is among the most sensitive plants, and a rate of 138.75 g a.e. ha⁻¹ of glyphosate resulted in nearly 90% dry biomass reduction (de Paula Medeiros et al., 2023). Our results showed that fennel was highly sensitive to glyphosate, similar to other susceptible crops. However, fennel exhibited lower sensitivity than tomato but greater sensitivity than soybean.

Sulphonylurea herbicides are widely used, yet their unintended off-target movements, such as drift and runoff, have not been comprehensively studied (Askew et al., 2022; Jester et al., 2022). Askew et al. (2022) demonstrated that application of flazasulfuron at 5.2 g ai ha⁻¹ or trifloxysulfuron sodium at 3.0 g ai ha⁻¹ to corn seedlings in a corn bioassay resulted in approximately a 40 % reduction in dry biomass compared to non-treated controls. Our biomass reductions at 3.13 g ai ha⁻¹ flazasulfuron (~59%) exceed corn bioassay declines reported for drift-equivalent SU doses. This result suggests greater fennel sensitivity under similar sub-lethal exposure.

CONCLUSIONS

This study proved that fennel is highly sensitive to sub-lethal rates of both glyphosate and flazasulfuron under controlled climate room conditions. Both herbicides induced significant reductions in plant height, visual injury scores, and above-ground dry biomass, even if they were applied at relatively low application rates. However, flazasulfuron exhibited greater crop injury than glyphosate. These results emphasized the potential risk of herbicide drift from adjacent fields or orchards to fennel crops. Therefore, strict drift management strategies and careful herbicide application practices should be implemented to protect fennel fields, especially in regions where these herbicides are commonly used in nearby cropping systems. Future research should focus on field-scale evaluations and recovery potential following sub-lethal herbicide exposure to better inform integrated weed management strategies.

ABSTRACT

Drin River is the longest river in Albania with about 285 km length. Its two branches start respectively from Lake Ohrid and from its waterfall in Western Kosovo. The fish fauna of the Drin River consists of 52 species. Of these, 9 species have a significant threat status according to the IUCN, while only 13 of them are included in the list of threatened species for Albania. In order to assess the global and national threat levels of the fish species of Drin River, after the preparation of the species list, IUCN global and national threat statuses have been established, as well as comparisons and discussions have been made for species or groups of species in different cases. From the list of threatened species for Albania, in 9 cases the national level of threat is higher than the global one, for 3 species it is lower and for one it's the same. More than half of the fish species of the Drin River belong to the group of market fish species that are used for consumption. The river Drin should be considered as an important habitat with many values in terms of fish fauna. Therefore, it is necessary to carry out in-depth studies and take measures to preserve the populations of these species.

Key words: fish, threatened species, Drin River, biodiversity, ecosystem.

INTRODUCTION

There is no doubt that lists of threatened species fulfil important political, social, and scientific needs. For example, endangered species lists are very useful in explaining to people the importance of species recovery or loss. In most circumstances, they are the only tools available that have a clear social mandate and that rely on substantial ecologically sound knowledge. (Possingham et al., 2002). However, these lists have many limitations in effectively addressing the problems they are used to solve, and ill-advised application carries its own risks. (Mace & Lande, 1991)

Biodiversity research and data are very important in several ways, not only for researchers but also for state institutions that design policies and act to protect biodiversity. Too often biodiversity data are not available to institutions, researchers and the general public in many countries or, if available, they are scattered in several different repositories that differ in platform, structure and data semantics. (Edwards et al., 2000, Schuurman & Leszczynski, 2008, Heidorn, 2011, Martellos & Atorre, 2012)

Although with a small area, Albania is internationally known for its high level of biodiversity, habitats and ecosystems. One of these important natural resources is the river Drin.

The Drin river basin covers a geographical area of about 20,000 km² in the western Balkans; the basin extends through: Albania, Greece, North Macedonia, Kosovo and Montenegro. The Drin river basin is a hydrological interconnecting system consisting of the transboundary basins of Lakes Large Prespa and Little Prespa; Lake Ohrid; Lake Shkodra; The Drin River including its tributaries, the White Drin, the Black Drin and the Buna River. (Pano, 2008)

The Drin River flows through the mountain area of the Western Balkans towards the Adriatic Sea, thus providing the third and largest river discharge in the European Mediterranean. (Dhora, 2017)

Drin River is formed by the confluence of two rivers: Black Drin and White Drin. Black Drin covers an area of 9209 km² (including the Prespa and Ohrid watersheds); 58% of this area lies in Albania (5,369 km²) and 42% in North Macedonia (3,840 km²) and flows north from North Macedonia to Albania (Kukes), where it joins the White Drin which originates on Mount Zljeb in Kosovo, and encompasses an area of 4,964 km², 88% in Kosovo, and 12% in Albania. It then flows west for about 335 km, of which 285 km flows within Albania and the rest in Kosovo, North Macedonia and Montenegro. Its hydrological network is dense, consisting of numerous rivers, streams, springs and natural lakes. One of the branches of the Drin joins the Buna/Bojana River near the city of Shkodra and the other branch flows directly into the Adriatic Sea south of Shkodra, near the city of Lezha (Keci et al., 2022). The connection of the Drin river with the Buna River, right next to Shkodra Lake, makes this river affect the fish fauna not only of the Buna river, but also of the Shkodra lake. (Dhora et al., 2016)

The list of fishes of the river Drin contains 52 species which give a considerable value to this ecosystem. (Dhora, 2020). This fact shows the regional fauna-forming importance of the Drin River, as a very valuable resource in the entire hydrological network of the Balkan Peninsula. Considering the great value of this class of vertebrates, we have carried out this study in order to highlight their current situation and the need to preserve these species. The comparison between the global status according to the IUCN ([http 1](http://1)) and the national one, as well as the assessment of their condition in terms of their presence in the ecosystem, is seen as a valuable study by us, presenting the international importance of this group of species.

An important aspect is the treatment we have given to market and common species. Along the banks of the river Drin lives a significant population of inhabitants who have fishing as one of the economic alternatives of living. Many of the Drin fishes are poorly studied and further research will most likely lead to taxonomic revisions of the species (Holcik & Soric, 2004). Consequently, the recognition, monitoring and protection of fish species takes on even greater importance at the national and regional level.

MATERIAL AND METHOD

The list of fishes of the river Drin is taken from the publication of Dhora (2020) where the updated list of fish species of Albania according to ecosystems is given.

After ranking the list, for each species in particular, the verification of the actual global status of the IUCN in 2025 was made. Also, from this same source, the population trend for each species in particular, whether it is increasing, decreasing or stable, was obtained. In the column next to it, the year when the information was obtained and the assessment made by the IUCN for each species is placed (IUCN, 2025). For the populations of the species that this source did not have information on, the note "?" has been placed.

In the following, based on the publication of Dhora (2018), a column has been placed for the inclusion or not of each species in the list of common species of the fauna of Albania.

Then the threat status in Albania was determined for each species separately. For this purpose, we have mainly relied on Order no. 1280 dated 20.11.2013 of the Minister of Environment "For the approval of the red list of wild flora and fauna".

Also, based mainly on the publication of Dhora (2022) but also on the local tradition, we have identified the market fish species in our country, for which the corresponding note has been placed.

All these data have been put in a table on which we have based to make the relevant comparisons and discussions.

The 9 categories of the Red List (IUCN) are listed below:

Threat categories:

EW - Extinct in the wild

EX - Extinct

VU - Vulnerable

EN - Endangered

CR - Critically endangered

Other categories:

NT - Near threatened

LC - Least concern

DD - Data deficient

NE - Not Evaluated

RESULTS AND DISCUSSION

Below are lists of fish species of the River Drin and relevant discussion of the species in particular. The list of fishes of the Drin River includes 52 species, which are grouped into 11 orders and 18 families. The largest family is Cyprinidae with 19 species.

Table 1. Information about fish species of Drini River

As can be seen from the list of fish species in Drin River, 15 species have NT status, 26 species with LC status, 3 VU species, 1 EN species, 5 species with CR status and for 2 species there is insufficient DD data. The most endangered family is the Acipenseridae family with all three species in the critical stage of existence. However, if we look at the population trend, for *Acipenser naccarii* it is increasing, which gives hope for the improvement of the situation at the global level.

While for the other two species, the population is decreasing. Regarding the situation in Albania, the species of the genus *Acipenser* have the EN status of threat, which shows that the situation in our country is not good. While the species *Huso huso* is not evaluated at all in the Red List for Albania. The first two species (*Acipenser* sp.) are also market species in Albania and have had a considerable use until a few decades ago. While in recent years they have become very rare and have disappeared from the market, which is also consistent with the status given to them on the red list of Albania.

The family Petromyzontidae consists of two species in the Drin River, which have a relatively low threat status (NT and LC). However, of interest is the species *Petromyzon marinus* whose population trend is decreasing and such continuity may increase the level of threat to it. At the national level, the situation for this species is even more serious, as it has been assessed with the VU threat status. While for the species *Eudontomyzon stankokaramani* we have a lack of data on the population trend from the IUCN. This species is not even included in the red list of Albania.

The family Anguillidae is represented only by the species *Anguilla anguilla* in the river Drin. Despite the fact that this species has a CR status of global threat and the population is declining, in Albania it is a market species, it is part of the list of common species (Dhora, 2018) and there is no threat level in the red list for our country. The situation of this species should be studied in more detail for Albania, since by comparing the global threat level according to the IUCN, the population trend and the occupations made in recent decades in Shkodra Lake (Dhora, 2022) as one of the largest water ecosystems in Albania, it turns out that this species is not in a very good situation in our country and may have a tendency to decrease.

The family Atherinidae includes only one species in the river Drin, *Atherina boyeri*. This species has the LC level of threat and according to the IUCN its population is declining. As for Albania, apart from the fact of its physical existence, there are no other studies to show its current state.

The Clupeidae family in the Drin River is represented by the two species *Alosa agone* and *Alosa fallax*. Although for the second there is no data on the global population trend, the situation does not seem worrying for both species. They have the threat level LC and for *A. agone* the population is stable. As for Albania, *Alosa fallax* is not in a satisfactory situation. It has a nationally threatened VU status, but is called a common species and continues to be one of the market species for consumption. The situation of this species in Albania should be looked at more carefully, as the national threat status indicates that it is declining and if it continues in this way it may lead to its further threat.

The family Balitoridae is represented by the species *Barbatula sturanyi*, which globally has the NT status of threat, while there are no data on the population trend. As for her situation in Albania, there is no data at all. Of course, it would be worthwhile to conduct scientific studies to assess the situation of this species in Albania.

The family Cobitidae and the species *Cobitis ohridana* are not presented with a high level of threat, either globally or nationally. The global NT status of the IUCN and the LC status for Albania show the relatively good situation of this species. However, two aspects should be taken into account: its

world population is declining and this species is part of the list of common species of Albania (Dhora, 2018), which allows its fishing in significant quantities.

The largest fish family of the Drin River is the Cyprinidae with 19 species. At the world level, 3 species represent the greatest importance in terms of their status: *Gobio ohridanus* (EN), *Pelasgus minutes* (VU) and *Scardinius knoezevici* (VU). Currently the IUCN has no information on the population trend for these species globally. While for Albania the situation of these three species is different. Two of these species, *Pelasgus minutus* and *Scardinius knoezevici* are part of the list of common species for Albania (Dhora, 2018). Also, they have no threat status in Albania and *S. knoezevici* is part of the list of market species (Dhora, 2022). While the species *G. ohridanus* has LC status for Albania. However, considering the global threat status, these three species should be kept in mind in our country as their situation can change rapidly.

For 7 species from the Cyprinidae family, we have a global population decline. For one species *Rhodeus amarus* we have an increase in the population, while for the rest there are no data at the global level. While at the national level, only three species are included in the red list of Albania and have LC status of threat (*Barbus rebeli*, *Chondrostoma nasus* and *Gobio ohridanus*), while the rest are not included in the red list of Albania at all. In this respect, it would be necessary to study this family in more detail and to know the current population situation for each species. In addition, 12 species of this family are market species and therefore take on greater importance at the national level.

The family Cyprinodontidae and the only species in this river *Aphanius fasciatus*, globally has LC status of threat and the population is in decline. While in Albania its situation seems more worrying, it has the EN status of threat and is not a common species at the national level.

The two species of the Poeciliidae family, *Gambusia holbrooki* and *Poecilia reticulata*, are presented in a relatively non-disturbing situation worldwide. They have LC status according to the IUCN and their populations are in a stable state. However, the latest IUCN estimates are made over a decade ago and therefore the trend of their populations is not certain if it continues to be the same in recent years. While for Albania, only *P. reticulata* is of interest as it has an EN status of threat and must be kept in attention with continuous monitoring for the study of its population.

The Blennidae family with its two species does not pose a concern as it has a relatively acceptable situation at the global and national level for Albania. The threat stage LC at the global level, and LC for only one of them at the national level indicates that their situation currently does not appear to be problematic.

The family Gobiidae and the species *Gobius paganellus* appear relatively stable worldwide according to the IUCN, with LC status of threat. As for Albania, there is no inclusion of it in the red list of threatened species.

The two species of the genus *Dicentrarchus* of the family Moronidae are in a globally non-concerning situation, with threat statuses (NT and LC), but the world population trend is decreasing for *D. labrax* while for *D. punctatum* there is no information. As for Albania, both of these species are market species and are not included in the country's red list.

The Mugilidae family has 5 species, whose populations worldwide are declining. While the threat statuses for 4 of them are NT and only one has LC. Since world populations are declining and all are market species for Albania, it is necessary to conduct studies at the national level to control the population trend and the level of threat of these economically important species.

The Percidae family is represented by two species that globally have LC status, but their populations are in a stable state. While in Albania only *P. fluviatilis* is included in the market fish list and none of these two species is included in the Albanian red list.

The species *Platinchthus flesus* of the family Pleuronectidae globally has LC status, but there are no population trend data. While at the national level for Albania, there is no information on the situation of the population and it is not included in the country's red list. This species is considered a market species for the country.

The Salmonidae family consists of 5 species in the Drin River, all market species in Albania. At the world level, the two species *Salmo balcanicus* with CR status and *Salmo marmoratus* with VU status present more interest. While for Albania, in addition to the species *S. marmoratus*, which at the national level has the status EN, the species *S. farioides*, which has the status VU of threat, is also of interest. This species is even part of the list of common species of the Albanian fauna (Dhora, 2018). For the other two species, *O. mykiss* and *S. dentex*, the situation at the world and national level is not worrying, although more scientific studies are needed for the latter.

The family Syngnathidae in the Drin River is represented by only one species *Syngnathus abaster*, who has LC status of global threat, but there is no information on the trend of this population. While at the national level for Albania, it is not included in the red list of the Albanian fauna.

CONCLUSIONS

The fish fauna of the Drin River consists of 52 species. Of these, 9 species have a significant threat status according to the IUCN (VU, EN, CR), while only 13 of them are included in the Red List of threatened species for Albania.

From the list of threatened species for Albania, in 9 cases the national level of threat is higher than the global one, for 3 species it is lower and for one it is the same. Over 50% of the fish species of the Drin River belong to the group of market species that are used for consumption.

It is worth noting that 41 species (79%) of fish are relatively not threatened or threatened to a low degree.

In 9 cases of species included in the Red List of Albania, the threat status for Albania is higher than that at the global or European level, so these species face a higher level of threat in our country. We believe that this is mainly related to the environmental condition of ecosystems and the negative effects they suffer mostly as a result of human activity. It is also found in species whose populations at the global or European level are stable or on the way to improvement.

Recognizing their regional situation as well as the importance that the group of fish has for the local and regional economy, as well as from its position in the food chain of different birds, it is necessary that their populations should be monitored and given even a minimal protection status, since the perspective in relation to the world population trend is not promising.

The species that at the global and/or European levels are really threatened (CR, EN, VU) and that are not included in the red list of fauna species in Albania should be treated with special attention, monitoring their populations and giving the necessary conclusions for their management.

INFLUENCE OF TEMPERATURE ON FERMENTATION RATE IN PRODUCTION OF DIFFERENT WINE TYPES

ABSTRACT

Wine production is a complex process that integrates traditional methods with modern scientific approaches. The quality, variety, and processing methods of grapes are among the key factors determining wine characteristics. Grapes, with their natural content of sugars, organic acids, and phenolic compounds, are considered an ideal raw material for producing various wine types. The quality attributes of wine are directly influenced by grape cultivation conditions, the maceration process, harvest maturity, and production techniques. Additionally, control parameters such as temperature during the fermentation process significantly affect both production efficiency and the sensory and chemical properties of the final product. This study investigates the effects of temperature control and maceration on the fermentation process in the production of different wine varieties. Specifically, the impact of temperature on fermentation rate was statistically analyzed using red, rosé, and white wines produced from the Papaskarası grape. The study was conducted based on experimental design principles, and statistical analysis revealed that both wine type and temperature significantly influenced fermentation rate ($\alpha = 0.05$), with wine type having a greater effect than temperature. Red wine completed fermentation in the shortest time, particularly at 25°C, due to enhanced yeast activity from phenolic and nitrogenous compounds during maceration, while rosé and white wines required longer durations. Higher temperatures (25°C) reduced fermentation time compared to 15°C, and lower temperatures preserved aromatic properties in rosé and white wines. The findings are discussed in the context of different wine types, highlighting the critical role of temperature and maceration in optimizing production efficiency and wine quality.

Keywords: Wine, Fermentation, Maceration, Phenolic compounds, Density

INTRODUCTION

Throughout history, grapes have held significant importance not only as a fruit but also as a raw material for various products due to their nutritional value and sensory properties. Grapes are derived from the vine plant known as *Vitis vinifera* (Parihar & Sharma, 2021). The nutritional composition of grapes is characterized by a high sugar content (Venkitasamy, Zhao, Zhang & Pan, 2019). Additionally, grapes are rich in minerals such as calcium, potassium, sodium, and iron, and serve as an important source of vitamins, including vitamins A, B1, B2, niacin, and C. Generally, grapes consist of water, sugars, organic acids, phenolic compounds, pectic substances, aroma compounds, nitrogenous compounds, enzymes, vitamins, and minerals (Venkitasamy, Zhao, Zhang & Pan, 2019). Factors such as grape variety, soil and climatic conditions, applied technical and cultural practices, and particularly the degree of ripeness, significantly influence the composition of grapes (Çaşkurlu, 2023).

Grapes are cultivated for table consumption, drying, and winemaking purposes. The intense phenolic compounds present in grapes, particularly those grown for winemaking, determine their color

and flavor (sensory properties) (Hornedo-Ortega et al., 2020). The chemical composition of grape must, influenced by factors such as grape variety, harvest maturity, climatic conditions, and soil structure, has a critical impact on wine quality. During the aging process, the stability of wine is primarily affected by its chemical composition, light exposure, oxygen levels, storage temperature, and storage duration. Consequently, the maceration process is the most significant factor distinguishing different wine varieties (Scepanovic, Vuletic, Christofi & Kallithraka, 2024).

Red Wine

In red wine production, harvested grapes are destemmed and crushed. The crushed grapes are then transferred to fermentation tanks via a peristaltic pump. In the fermentation tank, the broken grapes, including skins and seeds, are held under controlled conditions throughout the fermentation period. Alongside a selected constant temperature and mixing process, yeast addition facilitates simultaneous alcoholic fermentation and maceration (Morata, 2018). Fermentation temperatures typically range between 20–30°C for industrial yeasts. Higher temperatures enhance the extraction of phenolic compounds (tannins and color compounds) from the grape skins (Chidi, Rossouw, Buica & Bauer, 2015), resulting in intense, richly aromatic, and full-bodied wines. After fermentation is complete, the grapes are pressed to separate the must from the skins and seeds. Following clarification in the tank, the resulting wine is either aged or bottled based on production decisions.

Rosé Wine

In rosé wine production, destemmed and crushed grapes undergo a short maceration process with their skins and seeds, lasting between 4–24 hours, depending on the grape variety and desired wine characteristics (Radeka, Eukic & Peršuric, 2012). After maceration, the must is separated from the skins and seeds through pressing and transferred to fermentation tanks for fermentation. Following yeast addition, fermentation is completed under controlled conditions. After clarification, the resulting rosé wine is either aged or bottled based on production decisions. Fermentation temperatures for rosé wine typically range between 12–20°C (Salinas, Garijo, Pardo, Zalacain & Alonso, 2005). Rosé wines aim for fresh and fruity aroma similar to white wines, with slight tannin and color extraction, resulting in balanced, aromatic, and lightly tannic wines.

White Wine

Unlike other wine types, white wine production does not involve maceration (Bestulić et al., 2022). Destemmed grapes are crushed and immediately transferred to a press. The must, separated from the skins and seeds, is then moved to fermentation tanks for fermentation. Fermentation temperatures range between 10–15°C (Samoticha, Wojdyło, Chmielewska & Nofer, 2019). Preserving fresh, aromatic, and fruity characteristics is a priority in white wines. Lower temperatures result in slower fermentation, minimizing the loss of aromatic compounds and yielding a fresh, fruity, and vibrant flavor profile.

At the start of fermentation, grape juice has a high sugar content, resulting in a higher initial density (1.090–1.100 g/cm³). During fermentation, yeasts convert the natural sugars in the grape juice into alcohol and carbon dioxide (Figure 1) (Maicas, 2020). As the sugar content decreases and the alcohol percentage increases, the density decreases (Neto, de Castilhos, Telis & Telis-Romero, 2015). Density is typically measured at regular intervals to help winemakers monitor the progress of the process. When fermentation is complete, residual sugar levels are minimal, and the alcohol percentage has increased, causing the density to drop to a specific level. Winemakers generally consider fermentation complete when the density falls to approximately 0.995–0.997 g/cm³.

Figure 1. Fermentation metabolism of yeast

MATERIAL AND METHOD

The Papaskarası grape variety was sourced from vineyards in the Kırcaşalılı region of Edirne (Figure 2). *Saccharomyces cerevisiae* yeast was used in wine production. Using the same grape variety, red, rosé, and white wine varieties were produced, as shown in Figure 3.

Figure 2. Papaskarası grapes

Figure 3. Wine types used in the study: (A) white wine, (B) rosé wine, (C) red wine

All samples were processed in equal quantities under identical production conditions, with the same amount of production chemicals applied to each. Fermentation temperatures were set at 15°C and 25°C. Density measurements of the wines were conducted over approximately 14 days. These measurements were performed using a densimeter, as shown in Figure 4, and fermentation was considered complete when a density of 997 g/cm³ was reached. Statistical analysis was performed using the Minitab 18 program based on the fermentation durations. A general factorial design method was employed, with two factors: wine type and fermentation temperature. The experiments were conducted with two replicates ($\alpha = 0.05$).

Figure 4. Densimeter

RESULTS AND DISCUSSION

Density measurements were conducted over a 14-day period to monitor the fermentation process. Fermentation durations for different wine types at two temperature levels are presented in Table 1, while the data used for statistical analysis are summarized in Table 2. The results obtained from the Minitab program are shown in Table 3.

Table 1. Density Values in the Production of Different Wine Varieties

Table 2. Effect of Different Temperatures and Wine Varieties on Fermentation Time

Wine types	Red wine		Rosé wine		White wine	
Temperature (°C)	Fermentation time (day)					
15	10	10	10	11	10	11
25	8	7	9	9	9	9

Table 3. ANOVA Table

Variation sources	Sum of Squares (SS)	Degrees of Freedom	Mean of Squares (MS)	F ₀	p value
Temperature	10,0833	1	10,0833	37,23	0,0000
Wine type	2,6667	2	1,3333	4,92	0,040
Interaction	0,6667	2	0,3333	1,33	0,332
Error	1,500	6	0,2500		
Total	14,9167	11			

In this study, the main factors, wine type and temperature, were found to significantly affect fermentation rate ($\alpha = 0.05$). The effect of wine type was observed to be greater than that of the selected temperature values. However, no significant interaction was observed between wine type and

temperature ($p > 0.05$). As shown in the main effects plot, red wine completed fermentation in the shortest time, while rosé and white wines took the longest. Examination of the temperature effect in Figure 5 indicates that fermentation time decreased with increasing temperature.

Figure 5. Main Effects Graph

During fermentation, sugars are converted into alcohol and carbon dioxide, resulting in a decrease in wine density. In wine production, a prolonged period of stable low-density values indicates the completion of fermentation (Nelson, Boulton & Knoesen, 2022). Winemakers can monitor this change to determine whether fermentation is complete. In this study, the effects of maceration and temperature were evaluated based on the density values of the wine.

Maceration is a process in winemaking that facilitates the transfer of phenolic compounds, color pigments, and aromatic components from grape skins, seeds, and pulp into the must or wine (Morata, González, Tesfaye, Loira & Suárez-Lepe, 2019). The maceration process influences color and polyphenol extraction, aromatic profile development, tannin extraction, fermentation rate, fermentation temperature, and chemical stability during alcoholic fermentation. Studies on the duration of maceration show that shorter maceration periods yield lighter, fruitier wines, while longer periods produce more tannic, complex wines with higher aging potential (Casassa, Bolcato, Sari & Barda, 2021). In this study, the greater influence of wine type on fermentation rate is attributed to the maceration process. It was concluded that, during red wine production, nitrogen and bioactive compounds present in grape skins enhance yeast activity during alcoholic fermentation, thereby accelerating the process. A study examining the effects of different maceration techniques on red and rosé wines reported that longer maceration periods improved sensory properties, overall wine quality, and aroma intensity. Conversely, short maceration periods resulted in distinct aromas and lower phenolic content, making them suitable for rosé wine production (Radeka, Eukic & Peršuric, 2012).

Temperature control during fermentation is critical for ensuring efficient yeast activity and achieving desired aroma and flavor profiles (Ruiz et al., 2019). Temperature directly affects yeast activity and, consequently, the rate of sugar conversion to alcohol and carbon dioxide. Analysis of the temperature values used for the wine types in this study revealed that higher temperatures positively influenced fermentation rate. Regardless of sensory properties, red wine completed fermentation in

the shortest time at 25°C. A study on the effect of fermentation temperature on rosé wine production used temperatures of 5°C, 10°C, and 15°C. Wines produced at 15°C exhibited the highest color values and the lowest alcohol content. Additionally, sensory analysis tests indicated that the most preferred rosé wine was produced at 15°C (Salinas, Garijo, Pardo, Zalacain & Alonso, 2005).

CONCLUSIONS

This study evaluated the effects of temperature and maceration processes on the fermentation of red, rosé, and white wine varieties produced from the Papaskarası grape. The findings demonstrate that both temperature and wine type significantly influence fermentation rate. Specifically, fermentation processes conducted at 25°C were observed to complete more rapidly compared to those at 15°C. Furthermore, red wine exhibited the shortest fermentation duration, attributed to the contribution of phenolic and nitrogenous compounds from grape skins during maceration, which enhanced fermentation. In rosé and white wines, lower temperatures were found to positively affect the preservation of aromatic properties. The study's findings underscore the critical importance of selecting appropriate temperature and maceration durations in wine production to optimize both production efficiency and product quality. Additionally, this study provides valuable insights into the impact of production techniques on wine quality across different wine types.

MIGRATION OF FRESHWATER FISHES IN TÜRKİYE AND OBSTACLES ENCOUNTERED BY FISHES DURING MIGRATION

Çiğdem GÜRSOY GAYGUSUZ¹

¹ Trakya University, Keşan Vocational Collage, Edirne, Turkey

Corresponding author e-mail: cigdemgaygusuz@trakya.edu.tr

ABSTRACT

Türkiye's inland waters have significant potential in terms of fish species diversity. Recent studies have reported that 427 fish species, 215 of which are endemic, inhabit Türkiye's inland waters (lakes, rivers, dams, etc.). Some fish species prefer a settled life, while others have to migrate long or short distances. Physical, chemical and biological factors such as light, water depth, currents, pollution, sexual development, spawning, feeding and escape from predators play an important role in fish migration. During migration, various natural or man-made hydraulic obstacles, especially those that are not suitable for the biology and ecological requirements of freshwater fish, put pressure on the development, reproduction and genetic characteristics of many fish species and may cause some species to the point of extinction. In order for fish migrations to take place as they should, the removal or reorganization of some existing obstacles in rivers and even the construction of suitable fish passages on river systems positively affect the continuity of fish populations.

In this study, the barriers that harm the diversity of freshwater fishes in Türkiye and what can be done to prevent the damages caused by these barriers were evaluated.

Keywords: Freshwater fish, Fish migration, Hydraulic barriers, Biodiversity

INTRODUCTION

Freshwater ecosystems are rich and important structures in terms of biodiversity. However, biodiversity in most of these ecosystems is relatively poorly understood (Filiz and Tarkan, 2017). Türkiye is one of the countries in Europe that stands out for its diversity of freshwater ecosystems, with 25 hydrological basins (Ministry of Agriculture and Forestry, 2020). Türkiye's inland waters (lakes, rivers, wetlands, dams, etc.) host a variety of living species and contribute significantly to biodiversity with 427 fish species. Of these species, 215 are endemic (Çiçek et al., 2023). Most fish species generally prefer a sedentary lifestyle. Species that live in a specific environment do not move, or they migrate daily between pelagic and coastal zones. Some species (trout, eels, etc.) migrate over long or short distances between different aquatic ecosystems to continue their generations (Geldiay and Balık, 2009; Tut Deng and Tsegaye Demisse, 2023).

Migration has a significant impact on population structure and can influence species composition in the region. Fish migrate depending on their developmental stages and different functions throughout the year (DSİ, 2016; Avşar, 2005). Migratory fish migrate either individually or in schools and generally return to their place of origin (Tut Deng and Tsegaye Demisse, 2023). But some species undertake non-returnable migrations.

Fish migrate for various reasons. The main reasons are spawning, feeding and sheltering.

Feeding Migration: Both young and mature individuals undertake this migration. It is a type of migration undertaken by adult fish or newly hatched larvae after spawning to waters rich in food sources in order to grow and store energy (Avşar, 2005).

Wintering Migration: At the end of summer, during the winter months, the migration of young and old individuals from their current location to a more suitable area to escape from unfavorable conditions is called sheltering migration (Avşar, 2005).

Reproduction (Spawning Migration): This is a type of migration undertaken by sexually mature fish, consisting entirely of adult individuals, for the purpose of reproduction (Avşar, D. 2005). It is important to find the most suitable, safe and nutrient-rich environment for the juveniles.

Fish may migrate for reasons other than these primary migration causes. Particularly during early developmental stages (eggs, larvae, and immature juvenile fish), they may be drifted along by water currents as they are unable to swim against them. Changes in their habitats may drive them to disperse to different areas (DSİ, 2016).

TYPES OF FISH MIGRATION

Fish migration can be categorised into different types (Şimşek et al., 2022; Geldiay and Balık, 2009).

Diadromous: This is a type of migration that occurs between the sea and freshwater. Fish that undertake this type of migration adapt to the changing salinity of their environment through their osmoregulation abilities, as they move between aquatic ecosystems with different salinity levels.

a-Anadromous: This refers to diadromous migration of species that can reproduce in freshwater but complete their growth phase in the sea. Salmon, sea trout, and sturgeon are examples of this type of fish. *Salmo labrax* (Black Sea salmon) is a species that enters Turkey's inland waters to reach its spawning grounds. These fish, which typically migrate long distances, expend a great deal of energy during their migration and die after spawning.

b-Catadromous: This refers to diadromous migration of species that can reproduce in the sea but complete their growth phase in freshwater. Eels (*Anguilla anguilla*), which live in coastal waters and some lagoons in Turkey and migrate to the Gulf of Mexico to spawn, are an important catadromous fish species.

c-Amphidromous: A special type of diadromous migration undertaken by species that move between saltwater, brackish water and freshwater habitats.

Potamodromous: These are migrations that occur solely in freshwater. Some freshwater fish migrate upstream of lakes and rivers to spawn. A typical example of this group is *Alburnus tarichi* (pearl mullet) found in Lake Van.

Oceanodrom: These are migrations that occur only in the seas. Oceanodromic migrations occur for various reasons and can take place both horizontally and vertically, over both short and long distances.

FACTORS BLOCKING FISH MIGRATION

Fish move not only laterally but also longitudinally (upstream and downstream along the main channel) in their habitats. Fish may encounter various limitations and difficulties while migrating. Changes in habitat conditions affect fish migration behaviour (Tut Deng and Tsegaye Demisse, 2023). Factors hindering fish migration can be classified and examined as physical (structural), chemical, and biological.

Chemical Barriers

When domestic and industrial waste, fertilisers and agricultural pesticides enter aquatic systems, they alter the chemical composition of the water, causing water quality to deteriorate and harming the organisms living there. The wastes cause a decrease in the amount of dissolved oxygen in the water, which can lead to the death of fish. The toxic effects of wastes also cause fish fatalities. Pollutants entering the aquatic environment impair fishes' sense of navigation and smell. (Atamanalp et al., 2013; Küçük, et al., 2018).

Sediment on the bottom of aquatic systems, caused by erosion, deforestation, construction, and improper land use, prevents fish from finding food. Fish eggs and larvae are harmed by the decrease in water and oxygen levels in the environment. Fish whose senses of eyesight and smell and their ability to navigate are impaired find it difficult to migrate.

Biological Barriers

Alien and invasive species compete with native species for food and habitat in the aquatic environments they enter, and they contribute to hybridisation, habitat destruction, and even the transmission of diseases. They can feed on the eggs and larvae of native species living in the habitat they enter. Migrant native species populations, already struggling with other stresses, are further reduced and brought to the brink of extinction under the pressure of these invasive species. *Carassius gibelio* adapts better to the conditions of the habitats it enters than native fish species, is more successful in colonisation, and plays a role in displacing most native species from the environment (Tarkan, 2013; Tarkan et al, 2012).

Migration is the most vulnerable time for fish. Fish schools that gather at specific places for spawning migration (below dams, river narrow passages) are easy targets for poachers. This directly and severely affects the population's capacity to regenerate itself (Küçük et al, 2018).

Structural Barriers

These obstacles are man-made or natural structures that make it extremely difficult or impossible for fish to access their preferred habitats. Dams, hydroelectric power stations, weirs, regulators, embankments, culverts, irrigation channels, bridges on river systems, etc. structures can slow down, stop or change the direction of water flow by blocking rivers. The migratory movements of fish that encounter such changes in the aquatic environments they enter are restricted (İlhan et al, 2024).

Türkiye ranks among the countries with the most dams in Europe, having 861 dams. Nearly all major river systems, such as the Euphrates, Tigris, Çoruh, Kızılırmak, Yeşilırmak, and Sakarya, have been blocked by a series of dams (dsi.gov.tr). It has been reported that the migration of fish has been impeded in the Van Lake basin, one of Türkiye's important basins, due to the failure to construct fish passages and fish ladders to facilitate fish passage during the construction of dams, regulators and reservoirs (Elp et al, 2006).

The Büyükçekmece Lagoon (Istanbul), an important reservoir, was blocked from the sea by the construction of dam gates. Over time, the fish population has changed, affecting migratory species such as *Acipenser gueldenstaedtii* and *Anguilla anguilla* (Saç and Özuluğ, 2017).

FISH PASSAGES

Fish passages are hydraulic structures designed to provide suitable flow conditions for fish to swim easily without being harmed by natural and artificial obstacles encountered along their migration routes. Various fish passages and numerous variations of these passages have been developed. There

are four main types of fish passages. These are: Pool type fish passages, Denil fish passages (Larinier type), Vertical slot fish passages and Culvert-type fish passages (DSİ, 2016; Üçüncü and Altındağ, 2012).

Pool-type Fish Passage: It is one of the oldest and most commonly used types of fish passage. This fish passage is usually constructed for species with strong swimming abilities and requires a large area.

Vertical Slot Fish Passages: These fish passages have a similar system to pool type fish passages. There are curtains placed at regular intervals along the passage, and these curtains direct the flow of water.

Denil Fish Passages: The Denil passage consists of a linear channel with regularly organised, short-interval plates. The plates inside are positioned at an angle against the direction of water flow. These passages adapt to changes in water level.

Culvert-type Fish Passages: These are channels constructed in elliptical, rectangular, circular, pipe-arch or square cross-sections, used to convey water from one side of the road to the other in areas where culverts are required for fish passage.

In addition to these four types of fish passes, fish ladders, fish lifts, fish ramps and trap-type fish passes also contribute to finding ecological solutions for fish migration.

CONCLUSIONS

Many species that cannot change their habitat to meet their needs, becoming trapped in specific areas and experiencing intense pollution and fishing pressure, face the threat of extinction from the ecosystem. To eliminate these negative effects, freshwater ecosystems must be considered as a whole, the physical, chemical and biological characteristics of aquatic environments must not be overlooked, and species-specific solutions must be developed.

Fish passages are structures that play an important role in ensuring the continuity of fish migration. It is believed that the construction of fishways as environmentally friendly structures can prevent the problems fish encounter during migration (Üçüncü and Altındağ, 2012; Silva et al., 2017, Bozkurt and Yüksel, 2017). Following detailed research in areas where fish passages are required, passages with the necessary characteristics to meet the need should be constructed and regularly monitored. Interdisciplinary coordination should be prioritised during the design of the passages. The efficiency of fish passages should be monitored regularly, the necessary data collected and the results reported. The information obtained will be useful to experts and managers in better managing fish stocks.

Avoiding pollution, preventing overfishing and poaching, and stopping invasive and alien species from being released uncontrollably into aquatic habitats will also help protect fish stocks. New structures can be built to protect natural migration routes, or existing structures (dams, weirs, canals, embankments) can be removed to allow the natural process to take its course.

EFFECTS OF BLENDING DIFFERENT RATIOS OF COTTONSEED OIL WITH DIESEL FUEL IN A SINGLE-CYLINDER DIESEL ENGINE

Erdal Tunçer

Istanbul Health and Technology University Faculty of Engineering and Natural Sciences, Istanbul, Turkey.

e-mail: erdal.tuncer@istun.edu.tr

ABSTRACT

The persistent reliance on internal combustion engines, particularly within the transportation sector, continues to pose significant environmental challenges due to the emission of exhaust gases. This issue has intensified global efforts to identify and develop alternative fuels that can mitigate greenhouse gas emissions associated with fossil fuel consumption. Concurrently, the gradual depletion of petroleum reserves and volatility in fuel prices have introduced economic sustainability concerns. In this experimental study, the impact of blending conventional diesel fuel with 10% and 20% cottonseed oil by volume on engine performance and exhaust emissions was evaluated using a single cylinder direct injection diesel engine. The results demonstrated that the addition of cottonseed oil did not significantly affect engine power output or brake specific fuel consumption. However, a notable decrease in carbon monoxide (CO) emissions was observed, accompanied by an increase in nitrogen oxides (NO) emissions with higher biodiesel ratios. These findings indicate that cottonseed oil–diesel blends up to 20% by volume can be considered a technically viable partial substitute for conventional diesel fuel in compression ignition engines, with tradeoffs in emission characteristics.

Keywords: Energy, diesel engine, emissions, cotton seed oil

INTRODUCTION

The level of energy diversity and energy consumption is widely recognized as an indicator of a country's level of development. With the growing global population, meeting the increasing demand for energy and addressing associated economic factors have become critical challenges. In this context, the concept of sustainability requires balanced planning that considers energy production, resource diversity, costs, and environmental impacts. The continued use of internal combustion engines, coupled with the gradual depletion of fossil fuel resources, rising costs, and harmful emissions, has become a matter of growing concern for much of society. The use of biodiesel as an additive to petroleum-based diesel fuel in certain proportions is considered a viable alternative to mitigate these negative impacts [1–3]. Moreover, standard diesel fuel is known to be harmful to human health due to the emission of toxic oxides and its contribution to acid rain [4-5-6]. During the desulfurization process of diesel fuel, the removal of polar compounds results in a significant reduction in the fuel's lubricating properties [7]. These polar compounds typically form a protective layer or lubricating film between metal surfaces, thereby reducing wear and friction. The absence of such compounds in ultra-low sulfur diesel (ULSD) significantly decreases its lubricity [4]. Lubricity is particularly critical for diesel engine components such as fuel pumps and injectors, where proper lubrication is essential to prevent mechanical wear and maintain system efficiency [8]. To compensate for the loss of lubricity in diesel fuel, biodiesel has been increasingly used as a natural lubricity enhancer. Compared to mineral based

fuel additives, biodiesels derived from vegetable oils are considered environmentally friendly due to their biodegradability [9]. In this regard, several studies in the literature have focused on the use of cottonseed oil biodiesel. For instance, in a study conducted using a single cylinder, four stroke, direct injection diesel engine, different ratios of cottonseed oil were blended with diesel fuel to evaluate their impact on engine performance. When 10% cottonseed biodiesel was blended with diesel, the brake specific fuel consumption (BSFC) increased by 29.15%. However, average reductions in hydrocarbon (HC), smoke, and nitrogen oxide (NO) emissions were observed at rates of 12.89%, 4.12% and 8.84%, respectively, compared to standard diesel [10]. In another experimental study, diesel fuel was blended with cottonseed oil and 5% ethanol. The results indicated improvements in the fuel blend's physicochemical properties, engine performance, and reductions in harmful exhaust emissions. Additionally, a 7% decrease in kinematic viscosity was reported [11]. A more recent investigation examined an alcohol enhanced, water emulsified cottonseed oil biodiesel in a single cylinder diesel engine. Compared to conventional diesel, the emulsified blend improved combustion and significantly reduced exhaust emissions. Notably, the addition of 10% pentanol resulted in reductions of 14.3% in HC emissions and 12.8% in carbon monoxide (CO) emissions. Furthermore, a 1.4% decrease in brake specific fuel consumption was observed [12].

Distinguishing itself from previous studies, the present research experimentally investigates the effects of blending 10% and 20% cottonseed oil biodiesel by volume with standard diesel fuel on the performance and emission characteristics of a single cylinder, four-stroke diesel engine.

MATERIALS AND METHODS

In this study, a single cylinder, four stroke diesel engine, shown in Figure 1, was used at the Erin Motor R&D Center. To investigate the effects of the fuel blends on engine performance, two fuel mixtures were prepared by blending 10% and 20% cottonseed oil biodiesel by volume with 1 liter of standard diesel fuel. Before starting the tests, the engine was operated under no-load conditions until the radiator coolant temperature reached 82°C to ensure thermal stabilization. Once the coolant reached the desired operating temperature, engine tests were conducted at four different load conditions 25%, 50%, 75%, and 100% using a dynamometer. Initially, tests were carried out using standard diesel fuel. Subsequently, the same procedure was repeated for the fuel blends containing 10% and 20% biodiesel.

During the experiments, engine power, fuel consumption, and exhaust emissions specifically carbon monoxide (CO) and nitrogen oxides (NO) were measured simultaneously. Based on the collected experimental data, performance and emission characteristics were analyzed, and graphical representations of variations in power output, fuel consumption, and emission levels were produced.

Figure 1: Test Engine

Technical specifications and necessary information of the test engine are given in table 1.

Table 1: Technical Specifications of The Test Engine

General Characteristics	Technical Specifications

Engine type	Erin Motor Base Model	
Number of Valves	4	
Continuous Power (kw/rpm)	11.5	
	/ 1500	
Bore (mm)	108	
Stroke (mm)	127	
Combustion System	Direct Injection	
Compression Ratio	14.6 : 1	
Engine Cooling	Water	
Weight (kg)	157	

RESULTS AND DISCUSSION

Based on the experimental results, the effects of blending different proportions of cottonseed oil biodiesel with standard diesel fuel on engine performance and exhaust emissions were evaluated and illustrated through graphical analysis. When standard diesel fuel was used, the engine produced power outputs of 3.0 kW, 5.9 kW, 8.8 kW, and 11.4 kW under 25%, 50%, 75%, and 100% load conditions, respectively. With the addition of 10% and 20% cottonseed oil biodiesel, a slight decrease in engine power ranging from 0.1 to 0.2 kW was observed across all load levels. The effect of standard diesel fuel and the blended fuels (containing 10% and 20% biodiesel) on engine power output is presented in Figure 2.

These results indicate that the addition of cottonseed biodiesel to diesel fuel caused no significant change in engine power output. The observed power losses were minimal and within acceptable limits, suggesting that such blends can be used without substantial performance degradation.

Figure 2 : Power variation according to the load on the engine

Furthermore, under all load conditions tested, the addition of 10% and 20% cottonseed oil biodiesel to standard diesel fuel resulted in a slight reduction in fuel consumption. As shown in Figure 3, fuel consumption decreased consistently across all load levels, with the blend containing 10% cottonseed oil demonstrating the most favorable results. This indicates that the 10% biodiesel blend offers improved combustion efficiency compared to both standard diesel and the 20% blend, likely due to better atomization and oxygen content in the fuel.

Figure 3: Change in fuel consumption as a function of engine load and fuel type

During the experiments, carbon monoxide (CO) emission levels at various engine loads were measured and are presented in Figure 4. It was observed that under higher load conditions, particularly at 75% and 100% engine load, the addition of 20% cottonseed oil biodiesel to standard diesel fuel resulted in a noticeable reduction in CO emissions. At other load conditions and blend ratios, CO emission levels remained nearly unchanged compared to standard diesel.

Figure 4: Change in CO in engine exhaust emissions as a function of load and fuel type

The nitrogen oxides (NO) emission levels measured under different load conditions for standard diesel fuel and blends containing 10% and 20% cottonseed oil biodiesel are presented in Figure 5. Across nearly all load conditions, the addition of cottonseed biodiesel resulted in an increase in NO emissions compared to standard diesel fuel. This rise in NO levels is consistent with the higher combustion temperatures and oxygen content associated with biodiesel blends.

Figure 5: Change in NO in engine exhaust emissions as a function of load and fuel type

CONCLUSIONS

In this study, the effects of biodiesel blends containing 10% and 20% cottonseed oil by volume with standard diesel fuel on engine characteristics were investigated. Based on the experimental results, it

was found that blending cottonseed oil at these ratios led to a very slight reduction in engine power, with a maximum decrease of approximately 0.2 kW. However, under almost all load conditions applied to the engine, a reduction in the amount of carbon monoxide a harmful exhaust emission was observed, while a slight increase in nitrogen oxide (NO) emissions occurred. Additionally, a minor decrease in fuel consumption was detected. These results suggest that it is feasible to blend 10% to 20% cottonseed oil with standard diesel fuel for use in a single cylinder diesel engine without significant negative effects on engine performance.

SOURCES OF INSTITUTIONAL SUPPORT FOR SUSTAINABLE MANAGEMENT OF TREES FROM THE GENUS *Tilia* sp. IN BOSNIA AND HERZEGOVINA

Selma Vejzagić

International Burch University, Faculty of Economics and Social Sciences, Department of Management, Sarajevo, Bosnia and Herzegovina,

Corresponding author e-mail: selma.vejzagic@stu.ibu.edu.ba

ABSTRACT

The research of the three dominant linden species in Bosnia and Herzegovina as part of the DBU “MOE” 2021 scholarship program opened the door for a new perspective of these species in the Bosnian-Herzegovinian economy, primarily forestry as an industrial branch. Species from the genus *Tilia* in Bosnia and Herzegovina are characterized by a wealth of intra- and interpopulation diversity, and due to their good properties (primarily resistance to long-term drought) they are considered trees of the future. The goal of the wider research project is to assess the possibilities for raising linden nurseries in Bosnia and Herzegovina in the future, so that the country can provide high-quality, highly resistant planting material, which would be used in mass afforestation. Based on the review of transparent information of forestry companies in the country, it was learned that several companies are already growing linden trees in their nurseries. This article discusses how support could be provided to forestry experts, who could possibly promote the idea of more frequent planting of trees from the genus *Tilia* in Bosnia and Herzegovina in the future. Namely, Bosnia and Herzegovina as a country has a relatively complex administrative structure, however, this should not be an obstacle to sustainably managing forests of interesting genetic importance throughout the territory of Bosnia and Herzegovina. Namely, research conducted as part of the MOE scholarship (DBU.de, 2021) (if the report of this research is reviewed) indicates that linden, especially the species *Tilia tomentosa*, should be viewed as a potential tree of the future. Since the facts indicate that linden spreads in almost all habitats in Bosnia and Herzegovina and other countries of the Western Balkans, a logical question arises: "Why not support innovative ideas in order to find sustainable solutions for the wood market on the Balkan Peninsula?". Although it was relatively difficult to obtain detailed information on the popularity of linden in nursery production based on the data available on the websites of forestry companies, it is noticeable that the websites of forestry companies are relatively transparent and aesthetically adequately arranged. Forestry companies in Bosnia and Herzegovina transparently provide contact information, so that it is possible to establish contact and inquire about cultivation, protection and sale, as well as prices of planting material. This article relies on a literature review method, as well as an overview of available relevant information on the work of forestry companies and the species that are represented in nursery production for filling forest crops, planting plantations, but also for planting in alleys, on river banks and in floodplains. The main results of the research indicate that the functioning of forestry enterprises in Bosnia and Herzegovina is sufficient to sustainably manage species of the genus *Tilia*, especially considering that the Governments of both entities are willing to support the Master Plans for Afforestation and that there is an interest in carrying out the necessary afforestation of forest land with adequate tree species, as well as supplementing forest crops with valued commercial tree species.

Keywords: *Tilia*, Plant nursery, Sustainable Management, state organisation, governmental support

1.INTRODUCTION

In Bosnia and Herzegovina, according to Yugoslav sources (Herman, 1971), which are the most detailed on the subject of linden, there are relatively large areas of linden, which is considered a rare noble tree in many European countries. According to an oral statement by Professor Dr. Mikic (Oral Communication, 2016), there are two large linden sites on the European continent, namely Croatia (with linden dominance on the Bilogora mountain) and Serbia (with large linden complexes on the Fruska Gora mountain). In Bosnia and Herzegovina, there are relatively large linden forest stands in the Cazinska Krajina area, with a distribution center in Bosanski Petrovac and Sanski Most, while relatively large forests of the thermophilic species *Tilia tomentosa* extend in the Neretva River canyon (Herzegovina). Bosnia and Herzegovina is a country with a very complex administrative structure, which is closely correlated with all segments of the functioning of the state, and the administrative structure of the country directly reflects on the management of forest ecosystems. However, the existence of a complex state administration is not and does not have to be a reason for unresponsive forestry, and it is possible to establish an integrated system of management supervision of tree species of special importance, with the aim of preserving important highly resistant trees of the future for future generations.

The results of the Second Large-Scale Forest Inventory in Bosnia and Herzegovina (Lojo *et al.*, 2008), whose methodology was developed by prominent forestry experts in the country, indicate significant potential for future forest land reforestation with appropriate tree species, appropriate to the given forest ecosystems and soil conditions (its quality and history). Some of the forest land can be planted with species of the genus *Tilia*, as indicated by research within the MOE scholarships (DBE.de, 2021), within which a report was published indicating the importance of conservation and cultivation of linden trees, as well as the preservation of the genetic pool of existing linden forest stands in Bosnia and Herzegovina. In addition to this research, there is additional research indicating the importance of preserving linden for the future, in relation to protecting habitats from negative climate impacts. Thus, the authors Vejzagić, Ballian and Memisević-Hodžić (2021), in their study of the morphological diversity of *T. tomentosa* trees in Bosnia and Herzegovina and Serbia, state that this species is significant in the context of climate change, while Vejzagić (2022) also points to a similar significance, describing the potential connection between climate change and the appearance of multiple bracts in the fruits of silver linden (in the short communication on discovery of multibracteate linden in Mostar).

The institutions of the Federation of Bosnia and Herzegovina and the Republika Srpska can significantly help preserve the linden gene pool, not only in Bosnia and Herzegovina, but also in the wider region consisting of the Western Balkan countries. Thus, the authorities in Bosnia and Herzegovina can support the preservation of both linden forests and individual linden trees, which are important for genetic diversity (protection from illegal logging and any fragmentation of linden habitat). The importance of the Government of the Federation of Bosnia and Herzegovina and the Government of the Republika Srpska is also reflected in the support for the potential future production of seeds and high-quality seedlings resistant to drought and temperature fluctuations, which could help preserve populations of beneficial insects, such as bees, as well as protect the climate of local cities from overheating. Taking into account the research of Pigott (1992), who described the linden in Europe and presented information on pollen maps of Europe, according to which the linden was the dominant tree in the past, as well as the statements of Finschi *et al.* (2003) who explain what happened in the past with the genus *Tilia* in Europe due to the onset of the Ice Age, and if we add to the context of consideration the fact that forestry companies are obliged to do everything possible in cooperation with the academic community and authorities to ensure sustainable forest management, it is noted that

there is a need to investigate the framework of potential support for sustainable linden management in Bosnia and Herzegovina. Since there is no previous knowledge about this problem (scientific articles in Bosnia and Herzegovina), and since forest management elaborates of individual forest companies are extremely large documents, which are difficult to analyze in a short period of time, there was a need to collect basic information about which forestry companies are engaged in linden cultivation in Bosnia and Herzegovina, and whether there are documents that support the idea of linden production and planting in Bosnia and Herzegovina. The research was also guided by the fact that the countries of the Western Balkans chronically suffer from a lack of statistical data (Mueller and Hofmann, 2022), and care was taken to try to collect basic information about the problem under study.

2.MATERIAL AND METHOD

Research obtained basic information from different forestry companies in Bosnia and Herzegovina, that are existing and functioning at the moment, but also whose management data are transparently available at the web-sites. Since the simple review method of the given information was used, the main or key terms in the website search related to: 1) territory of management, 2) main services and production aims, 3) data about the plant nurseries and 4) data about the linden production. The report data of this review work should provide background information on where the potential for wider use of linden could be explored in the future.

However, since the organization of forestry companies in Bosnia and Herzegovina is complex in accordance with the division of responsibilities into different administration units, this indicates the need to conduct basic research whether the Governments of Federation of Bosnia and Herzegovina and Republika Srpska do have certain framework for the future afforestation, concretely whether the afforestation with linden trees is has already been planned. For the purposes of this exploration, the readings of two documents, “Republika Srpska Afforestation Master Plan” (Govedar and Mataruga, 2021) and “Afforestation Manual” (Visnjic, 2024) (provided on the website of the Association of Forestry Engineers and Technicians of Bosnia and Herzegovina), were analyzed. The aim of the readings was to identify whether linden species had been planned for the afforestation in the Federation of Bosnia and Herzegovina and Republika Srpska.

Some additional data about the forest companies, such as human resources or monitoring capabilities, were added in the results, since they could indicate the potential of individual enterprise level and the institutional support together to keep linden forest resources sustainable. Finally, to be emphasized is that the research did not use data from the forestry enterprise elaborates (which consist potentially more detailed data on the amount of linden trees planned for afforestation, in the frame of Plans of afforestation), but the research focused on the publicly available data from the web source.

Studied were the websites contents obtained from the following forestry companies: 1) Public company “Forestry economic society of Zenica-Doboj Canton” Zavidovici L.l.c., 2) Cantonal public company “Sarajevo-forests“ L.l.c. Sarajevo, 3) Public company "Forests of Tuzla Canton" J.s.c. Kladanj, 4) Forestry economic society “Central Bosnia forests” L.l.c. Donji Vakuf, 5) Forestry economic society “Herzeg-bosnian forests” L.l.c. Kupres, 6) Forestry economic society “Una – Sana forests” L.l.c. Bosanska Krupa, 7) Public company "Bosnian-herzegovinian forests" e.o. Sarajevo, 8) Public company "Forests of Bosnian Drina" L.l.c. GORAZDE, 9) Forestry “Central Neretva” J.s.c. Mostar, 10) Public company „Herzegovina-Neretva forests“ L.l.c. Mostar, 11) Forestry "PRENJE" J.S.C. Konjic, 12) "FORESTRY LJUTA" L.l.c. Konjic, and 13) Forestry company "FORESTS OF REPUBLIKA SRPSKA" J.s.c. Sokolac.

After reviewing basic data about the companies, basic information related to the possibilities of improving the sustainability of linden stands and/or their individual trees, through the existing

framework of institutional support and company capabilities, was clarified by the information sources from the institutional level (governmental supported documentation).

3.RESULTS AND DISCUSSION

The functioning of forestry companies in Bosnia and Herzegovina is to a certain extent supported by municipal (individual) and cantonal, but also Republika Srpska institutions, either through the means of those institutions directly, or through funds related to them and their services (offices), such different cooperations between forest companies and foreign organisations, who support afforestation projects in Bosnia and Herzegovina. There are different types of institutional support for the work of forestry companies in Bosnia and Herzegovina, about which a lot of information can be found on the official websites of forestry companies. Companies in general take care to publish information about partnerships and important projects on their websites. In the context of the analysis of potential addresses for seeking support in the future, when companies would seek help to harmonize their operations with the parallel negative consequences of climate change on forestry as an industry, and what also refers to support for the establishment of nursery production of resistant species of trees, from the available information it is known that support can be provided by the institutions in Republika Srpska and Federation of Bosnia and Herzegovina.

3.1. Individual forestry companies' data

The first company analysed is the P.C. "Forestry economic society of Zenica-Doboj Canton" Zavidovići L.l.c.. According to the transparent content on the website, this company deals with the cultivation and protection of forests, production planning and hunting. This company has been managing Cantonal forests since 2006. There are several business units (*Olovo, Vares, Visoko, Kakanj, Zenica, Zepce, Zavidovici, Maglaj, Tesanj*, and *Business unit "Natural Monument TAJAN Zavidovici"*), which are united in five wider forestry areas (*Gornjebosansko, Olovsko, Krivajsko, Kakanjsko* and *Natron-Usorsko-Ukrinsko*). This area manages forests and forest land on an area of 183,389.20 hectares, of which 69.12% are forests with natural regeneration, 15.22% are vegetative origin forests, 9.18% are forest cultures and plantations, and 6.48% are bare and unproductive areas. The mined areas cover 21,946.40 hectares. Seed and nursery production is very successful. Seed production of silver fir, Norway spruce, Serbian spruce, green Douglas fir, Scots pine, Austrian pine, European larch, European beech, ash, sycamore, Norway maple, Scots elm, small-leaved linden, sessile oak and chequer is stable. The nurseries owned by this company are: "Olovo", "Ajdinovici", "Zepce", "Zavidovici" and "Tesanj". (SPDZDK.ba, 2025)

In Sarajevo Canton is a center of the company C.P.C. "Sarajevo-forests" L.l.c. Sarajevo, which manages the forests and forest land of Sarajevo Canton. The activities of this company are: 1. Forest cultivation, 2. Forest protection, 3. Forest exploitation, 4. Construction and maintenance of forest transport infrastructure, 5. Bioengineering, 6. Environmental projects, 7. Hunting and hunting tourism, 8. Nursery production, and 9. Various projects and collaborations. The company was founded on November 24, 1999 with the main goal of ensuring the protection of forests and forest lands in the Canton area, and to this day it fulfills the mission and vision of the company. The area of forestry is divided into two sectors, of which the first sector, which is responsible for cultivation, protection and use of forests, includes: 1. Service for cultivation and protection of forests, 2. Service for planning and analysis, 3. Service for preparation and design, 4. Service for transport and maintenance of machinery, 5. Service for maintenance of forest communications and facilities, 6. Service for hunting and tourism, 7. Service for other forest products, 8. *Srednje* Forestry Administration, 9. *Hadzici* Forestry Administration and 10. *Trnovo* Forestry Administration, while the other sector has jurisdiction over

ecology and the management of protected areas, which is known as Service for Protected Areas. There are two nurseries, in Tarcin and in the settlement of Sedrenik. The two nurseries have a total area of 28,538 m², and the total capacity of these two nurseries is 700,000 seedlings. (SARAJEVO-SUME.ba, 2025)

Forestry company P.C. "Forests of Tuzla Canton" J.s.c. Kladanj is a cantonal forestry company engaged in the following activities: -Forest cultivation, -Forest protection, -Seed and nursery production, -Planning and production, -Hunting, and -Non-timber (secondary) forest products (sale). The cantonal company has over 530 employees, and in addition to the Directorate, there are four business units: Forestry "KONJUH" Kladanj, Forestry "SPRECKO" Zivinice, Forestry "MAJEVICKO" Srebrenik, and Forestry "Vlasenicko" Turalici. The area manages forests and forest land on an area of 44,713 hectares. The nursery production is good developed, and the "Budim potok" nursery is characterized by the successful production of the following species/tree *generas*: silver fir, Norway spruce, blue spruce, Scots pine, Austrian pine, European larch, *Juniperus spp.* and *Thuja spp.* (JPSUMETK.ba, 2025)

Forestry company F.E.S. "Central Bosnia forests" L.l.c. Donji Vakuf deals with the following activities: -Production, -Seed production and nurseries, -Ecology and protection, and -Forestry. Within this company there are 12 forestry units, which are named after the names of municipalities (*Jajce, Dobretići, Donji Vakuf, Travnik, Bugojno, Novi Travnik, Vitez, Gornji Vakuf - Uskoplje, Fojnica, Busovača, Kreševo* and *Kiseljak*). Twelve smaller units are included in four wider forest management areas: Forestry "Gornjevrasko", Forestry "Srednjevrasko", Forestry "Lasvansko" and Forestry "Fojnicko". The company has three nurseries: "Bugojno" Nursery, "Busovaca" Nursery and "Slimena" - Travnik Nursery. The nurseries have the following trees in the production: Norway spruce, Scots pine, Austrian pine, Bosnian pine, ash, and as for other species such as silver fir, Douglas fir, European beech, sycamore and oak, the organization of collection and production is ongoing. (SBKSUME.ba, 2025)

Next for the analysis was the F.E.S. "Herzeg-Bosnian forests" L.l.c. Kupres company, which performs the following activities: -Forest cultivation and other activities in forestry, -Forest exploitation, -Auxiliary services in forestry, -Hunting and service activities related to hunting, -Collection of uncultivated forest fruits and products, except forest assortments, -Processing of seeds for plant nursery material *etc.* The work within this company is carried out in the following business units: Directorate, Forestry *Bosansko Grahovo*, Forestry *Drvar*, Forestry *Glamoc*, Forestry *Kupres*, Forestry *Tomislavgrad*, Forestry *Livno*, and Work unit *RASADNIK*. The "Przine" nursery within this company has a very successful production of the following trees: Austrian and Scots pine, Norway spruce, silver fir, *A. platanoides*, *A. pseudoplatanus*, *A. negundo*, *F. excelsior*, *S. aucuparia*, *S. aria*, *C. betulus*, *T. platyphyllos*, *P. avium*, *M. sylvestris*, and *P. pyramidalis*. (HBSUME.ba, 2025)

Forestry company F.E.S. "Una - Sana forests" L.l.c. Bosanska Krupa is a cantonal company that performs the following activities: -Utilization of forests, -Timber wholesale trade, -Forestry (citizen) services, -Forest cultivation and protection, -Hunting, (trapping) and care of wild animals including appropriate services, -Forest cultivation and protection, -Production of other wood products, -Wood retail trade, -Cork and wicker production. The company has the following filiales: *Bihac, Bosanska Krupa, Bosanski Petrovac, Buzim, Cazin, Ključ, Sanski Most*, and *Velika Kladusa*. This company manages 172,687.14 hectares of forests and forest lands. In addition to operations within the units, the activity is also carried out in the "Cazin" nursery. (USSUME.ba, 2025)

In the eastern part of Bosnia and Herzegovina is the center of the forest company P.C. "Forests of Bosnian Drina" L.l.c. GORAŽDE. That cantonal forestry company in the Bosnian-Podrinje Canton for its main activities has: -Planning and production, -Forest cultivation and protection, -Additional activities (SUMEBPK.ba, 2025).

Forestry "Central Neretva" J.s.c. Mostar is a forestry company based in Mostar, in the Herzegovina-Neretva Canton. The main activity of the company is the utilization and cultivation and protection of forests. The company has been operating for about 25 years and has 34 employees. (SUMARSTVOMOSTAR.ba, 2025)

Forestry company P.C. "Herzegovina-Neretva forests" L.l.c. is located in Mostar and it participate in the following activities: -Cultivation and protection of forests, -Use and sale of all products of forests and forest land, -Construction and maintenance of forest communications and facilities, -Protection, maintenance and improvement of the general useful functions of forests, -Management of protected areas and forests with special purpose, -Planning in forestry, -Seed production, -Nursery production, and -Hunting and fishing and Tourism in forestry. The company has several units, namely: *Capljina, Jablanica, Konjic, Prozor-Rama, Mostar and Citluk*. (SUMEHNZK.com, 2025)

Forestry "PRENJ" J.s.c. Konjic is a company registered in the municipality of Konjic, and it participates in the following activities: -Forest cultivation, -Forest protection, -Forest utilization, -Construction and maintenance of forest transport communication, and -Nursery production. The nursery "Boracko jezero" has 2.60 ha surface. (SUMARSTVOPRENJ.ba, 2025)

"FORESTRY LUTA" L.l.c. Konjic is a company whose activities are: -Production, -Cutting and export of forest wood assortments, -Sales, and -Transport. (SUMARSTVO-LJUTA.ba, 2025)

In Sarajevo there is a center of P.C. "Bosnian-Herzegovinian forests" e.o. Sarajevo, the forestry company that can be singled out as an example of a company that provides support to all the aforementioned forestry companies, and whose professional assistance in reviewing and revising project documentation and forest management fundamentals is a huge professional help and support to all forestry companies' demands (BHSUME.com, 2025). This is thanks to its different departments from which every one provides professional service of writing, revising and supporting forestry elaboration documentation related to Forest management, Forest exploitation, Forest breeding, Forest protection and all sorts of forestry economic analyses.

Large forestry company F.C. "FORESTS OF REPUBLIKA SRPSKA" a.d. Sokolac is a comprehensive forestry company in the Republika Srpska, whose activities are: -forest utilization, -service activities in forestry, wood wholesale trade, and -Wood retail trade. The company manages 1,000,608.56 hectares of forests and forest lands, of which: - forests with natural regeneration reaches 469,164.64 hectares, - degraded forests reaches 14,528.97 hectares, - coppice forests reaches 226,336.88 hectares, - forest cultures reaches 48,687.63 hectares, - areas suitable for afforestation and management reaches 154,846.61 hectares, -areas unsuitable for afforestation reaches 68,374.82 hectares, -usurpations reaches 18,669.01 hectares. The volume of total wood mass amounts to 202,426,428 m³, of which deciduous forest wood participates with up to 122,429,391 m³, and conifers make up to 80,997,037 m³. The annual yield amounts to 5148250 m³. (SUMEREPUBLIKESRPSKE.org, 2025)

The business units of this company are: Forestry "Banja Luka", Forestry "Ostrelj-Drinic", Forestry "Panos", Forestry "Birac", Forestry "Gradiska", Forestry "Doboj", Forestry "Zelengora", Forestry "Cemernica", Forestry "Vrbanja", Forestry "Majevica", Forestry "Lisina", Forestry "Botin", Forestry "Jahorina", Forestry "Prijeedor", Forestry "Ribnik", Forestry "Sjemec", Forestry "Romanija", Forestry "Drina", Forestry "Maglic", Forestry "Borja", Forestry "Visocnik", Forestry "Vucevica", Forestry "Gorica", Forestry "Treskavica", Forestry "Klekovaca-Potoci", Forestry "Milici", Forestry "Rudo", "Karst Management Center" with headquarter in Trebinje, "Research-development and project center" with headquarter in Banja Luka, "Center for seed and nursery production" with headquarter in Doboj, Forest house "Ognjiste" with headquarter in Pale, and "Directorate of Public Enterprise" with headquarter in Sokolac. The nursery production is well developed and stable, and the

company has the following nurseries: "Stanovi" and "Usora" in Doboj, "Stupine" Nursery in Nevesinje, "Bisina" Nursery in Sekovici, "Gornja Puharska" Nursery in Prijedor, Trebinje Nursery (*Cupressus* spp., *P. pinaster*, *P. halepensis*, *P. nigra*, *P. heldreichii*, *Thuja* spp., *Cedrus* spp., *B. sempervirens*, *P. granatum*, *L. nobilis*, *Lavandula officinalis*, palm trees, *F. ornus*, *Euonymus* spp.), and the Nursery "Petkovaca" in Brcko (50 hectares surface). (SUMEREPUBLIKESRPSKE.org, 2025).

Figure 1. Forests of Republika Srpska, with clear administrative borders among Srpska's Forestry units/area. Source: <https://sumerepublikesrpske.org/index.php/strana-1/rg-niz-ci>

3.2. Institutional support in the form of afforestation approving documents

Forestry companies in the Federation of Bosnia and Herzegovina and Republika Srpska are encouraged to implement afforestation programs on their territory of management. Special care for the noble species of trees in the regional forest ecosystems should be anyway taken in the drought-affected areas, since they are mostly affected by climate, and so the forestry companies should take measures and plan activities to concretize protection measure, so that the forestry production does not suffer, as warned Kumar (2021).

The assumption that lindens can compete with oaks in Europe in terms of their biodiversity should be an incentive for increasingly frequent further molecular research and the search for hybrids in existing natural linden stands (populations). In order to preserve the linden trees in Bosnia and Herzegovina, and conserve the naturally occurring species with their subspecies and varieties for the future, it is necessary to learn in detail the behavior of linden trees within the species and between species, as well as the behavior of several linden species within one mixed stand. In this direction, it would be possible to go with a survey method, where the possibilities within forestry companies in the Republika Srpska and the Federation of Bosnia and Herzegovina could be investigated. If there are capacities (a sufficient number of employees) for additional monitoring of the behavioral patterns of linden trees in relation to changed environmental conditions, observing insects species that might appear (macroscopic identification on the terrain) and tracking whether the leaves and fruits of linden trees deviate from their typical appearance, there are then fundamentals for an integrated high quality

health condition and vitality parameters observations. The typical appearance of lindens growing in the territory of the former Socialist Federal Republic of Yugoslavia was described by Herman (1971), and that literature source should not be neglected in the process of systematic monitoring of behavioral patterns of linden complexes in the context of climate change.

Institutional support to forestry companies in the Republika Srpska and the Federation could, therefore, help further fragmentation of linden forests, and potential planning and financing of nursery production. Each forestry company is located within the territory of Republika Srpska and Federation (nurseries in Brcko District should be investigated in the future), which is characterized by different climatic, hydrological, relief and vegetative characteristics. It is important to note that through the review of transparent information on the activities of forestry companies and the species they grow for afforestation purposes, it was noticed that there is linden cultivation, both in the continental part of Bosnia and Herzegovina (Zavidovici area) in the west-southern Mediterranean parts (Kupres) of the country. It has been observed that there is an interest in buying linden seedlings, considering that this is a very attractive species for ornamental purposes and park planting, but the question arises whether and to what extent there is interest in planting this species as part of the afforestation program, which needs to be analyzed separately in the future. In a meanwhile the forestry companies exploit lawful support in the institutional documentation, such “Republika Srpska Afforestation Master Plan” (Govedar and Mataruga, 2021) and “Afforestation Manual” (Visnjic, 2024) (provided on the website of the Association of Forestry Engineers and Technicians of Bosnia and Herzegovina).

According to the data of the Federal Forestry Administration (FMPVS.gov.ba, 2025), the support of the Federal Forestry Administration has as part of its scope of work the collection of data and the maintenance of a database on the development of all forests in the Federation of Bosnia and Herzegovina, including their inventory. The federal administration, therefore, helps forestry companies that manage state-owned forests by preparing a draft of the Forestry Program of the Federation of Bosnia and Herzegovina. In addition, this institution determines the monitoring of the dynamics of the creation of forest management bases, which are documents that include all important information on forest management, (so forest stands as well as individual trees), which grow on public forest land. The provision of expert assistance for the development of forest management bases for forest management areas and forestry economic units in scope of companies is one of the most important assistances of this federal institution, but in addition, the development of plans and programs for extended biological reproduction of forests and programs and plans for afforestation of karst and bare forests is ensured. Establishing and maintaining registers and records of facilities for the production and processing of forest seeds and producers of forest trees and shrubs are under the authority of the institution. Monitoring the health status of forests, carrying out the work of the reporting and forecasting service and monitoring the condition and degree of forest damage is a very important function of institution, which can help in monitoring the health and condition of the habitus of the remaining linden trees, which may have the potential for cloning, i.e. more mass clonal nursery production, or which may be interesting from the aspect of seed collection for the necessary production of healthy and resistant linden seedlings. Since these trees may have commercial use in the future, and the production of linden wood for the production of furniture can potentially develop over time, it is important to familiarize all the stake-holders interested in protection of remaining linden trees and their stands with the described function of the Federal Forestry Administration, but also governmental offices in Republika Srpska. Namely, monitoring the economic condition of forestry industry, based on data obtained by cantonal administrations in the Federation of Bosnia and Herzegovina and from the Republika Srpska Governmental administration, as well as monitoring the prices of forest wood assortments and secondary forest products, including informing the public about the vitality condition of forests and the development of forestry branche, enables forestry companies to contact the Forestry

Administration of the Federation of Bosnia and Herzegovina and Government of Republika Srpska at any time, in order to propose possible solutions for their local market, the needs of their partners - customers, but also to suggest species for planting in the future. The development of an adequate solution plan in front of each forestry company is the product of its engineers, i.e. experts in forestry and various fields, which means the adequacy of those proposals for consideration and support by the Federal Administration and Srpska's Government. According to the obtained data, it is clear that forestry institutional based legislation is really made by forest experts and the full implementation could serve as an example how complex administration can in final provide a healthy framework for forestry laws implementation, when all legal criteria are met.

The preparation and creation of programs in the field of forestry, which are financed or co-financed from the dedicated fund of the Federation of Bosnia and Herzegovina, is closely correlated with the preparation and implementation of scientific research activities and the transfer of knowledge in the field of forestry. New knowledge useful for forestry must, in a certain way, be forwarded to the Federal Forestry Administration, so that it has insight into the solutions offered by forestry scientists, who may work in federal forestry companies (engineers, Masters and *PhDs* of Forestry). The preparation of expert opinions for the establishment and revision of forest management areas is the domain of the Federal Administration (FMPVS.gov.ba, 2025). Also, in order to protect an area with an existing high-quality stand, it is necessary to propose it to the Federal Forestry Administration. The reason for this is that the preparation and giving of opinions for the declaration of protected forests *and* forests with a special purpose is carried out in accordance with the powers and support of the named Administration. The organization of consultations and the provision of professional assistance to cantonal administrations and cantonal forest management societies is one of the functions of the Federal Administration, on which companies can always rely, therefore, frequent communication of forestry companies is significant and useful compared to sporadic ones. This kind of communication partially meets the recommendation of Kumar (2021). The same complex task in a form of huge support to Republika Srpska forestry units in giving the governmental office for forestry, which also supports the exchange of new scientific knowledge, ideas and solutions for existing or potential problems and helps developing cooperation between companies and institutions, as well as in terms of inter-units cooperation and strengthening awareness of the importance of protecting forests from the negative consequences of climate change. The Federal Forestry Administration and Government of Republika Srpska are supporting scientific achievements and experts recommendations from faculties for forestry (Faculty of Forestry in Banja Luka, Republika Srpska, and Faculty of Forestry in Sarajevo, Federation of Bosnia and Herzegovina), whose research projects draws the resources from the support of the Federal Ministry of Agriculture, Water Management and forestry companies themselves, and Government of Republika Srpska. Strengthening the bond between Ministries, forestry faculties and forestry companies increase the capacity to help the development of wider forestry regions. According to the Association of Forestry Engineers and Technicians (USIT.ba, 2025) of the Federation of Bosnia and Herzegovina (in Sarajevo), the support of the Croatian Forestry Society and the Faculty of Forestry of the University of Sarajevo is also very significant, not only in terms of scientific and professional assistance, but also in joint lobbying to find the best solutions for forestry as a whole and to promote solutions in the society, academic and business community. On the other hand, Faculty of Forestry in Banja Luka is host to Forest institute, which gathers forestry experts from the country and the Region, in aim to promote forest studies results and lobby for implementation of good scientific practices in the forestry of Republika Srpska (SF.UNI.BL.org, 2025).

In Republika Srpska, support is provided to the company F.C. "Forests of Republika Srpska" J.s.c. Sokolac, which is further implemented individually by all its individual business units, in accordance with the needs of those units. Due to climate differences and the presence of different

ecological-phytocenological areas in Bosnia and Herzegovina, there are certain differences in the focus of forest restoration support between the Federal Ministry of Agriculture, Water Management and Forestry and the Ministry of Agriculture, Forestry and Water Management of the Republic of Srpska. For example, the percentage representation of conifers and deciduous trees is different in Federation of Bosnia and Herzegovina and Republika Srpska, so there are certain differences in the amount of planting material for forest restoration and differences in the tree species, too. For example, the focus of nursery production within the business units of the “Forests of the Republika Srpska” company for the units located in the southern municipalities is focused on species that are designated as Mediterranean, while in the case of the northern municipalities, focus in production is more on continental species. In the Federation of Bosnia and Herzegovina, for example, the need to restore forests using Mediterranean species is in close correlation with the needs of the southern and west-southern cantons, on whose territory grow the species that require Mediterranean habitat and cultivation conditions. Therefore, there are certain differences related to the flow of information such as what are the needs of forest units regarding their climate and ecological conditions. Because of the complexity of the administration in Bosnia and Herzegovina, there are also certain specifics that play a huge role in the information flow and sometimes even can affect the speed of decision making processes, i.e. whether information from business units through forestry companies must go through the processing procedure first in the cantonal institutions, and then continue its journey to the competent ministry, or (as is the case in the Republika Srpska) that information travels directly, in the sense that it does not undergo processing at some mediate levels, but can continue its journey faster to the Ministry of the Republika Srpska. Ways of supporting forestry companies with all their units, can be found on the organized and transparent pages of the Ministry in the Republika Srpska. (VLADARS.rs, 2025, FMPVS.gov.ba, 2025)

Document “Republika Srpska Afforestation Master Plan” (Govedar and Mataruga, 2021) treats even *Tilia* species, by giving recommendations on breeding, planting, planting density index and percentage participation in the mixed forest stands. Recommendations for the linden planting are made also for the forest types, taking into consideration the habitat and vegetation characteristics for different forestry areas.

Precise data from this afforestation master plan are even given by individual *Tilia* species, as follows (Table 1).

Table 1. Surface for afforestation with *Tilia* specimens in hectares (according to Mataruga and Govedar, 2021)

Species	Dinarid s (ha)	Mediterranean region (ha)	Pannonian region (ha)	Illyrian-Moesian region (ha)	Total surface for Republika Srpska (ha)
<i>Tilia cordata</i>	605,08	710,47	13,01	147,96	1.476,52
<i>Tilia platyphyllos</i>	441,83	754,06	13,55	6,86	1.216,30
<i>Tilia tomentosa</i>	301,06	1.208,87	177,76	23,16	1.710,85

At this moment it is unknown (when analysing forestry companies website content) how much

of the recommended (calculated) plant material from *Tilia* genera have been planted, but it is obvious that detailed calculations exist in accordance to climate and habitat requirements.

Similar recommendations but more general, were published in Bosnia and Herzegovina in 2024 (“Afforestation Manual” by Visnjic, 2024, - provided on the website of the Association of Forestry Engineers and Technicians of Bosnia and Herzegovina), consisting detailed lists of species (non)resistant to drought, frost and temperature turbulences. Light requirements are also taken into considerations, while afforestation soil preparation process and preparation of the planting material was also described in detail. So, it is possible to conclude that governmental supported legislation and documents supporting afforestation programmes are completed by professional and fulfilling forest experts and Forestry professors works.

4.CONCLUSION

The institution support of the Government of the Federation of Bosnia and Herzegovina and the Government of the Republika Srpska could significantly help in the future, if the forestry companies decide to request the help of institutions for mitigating climate change. In accordance with the reviewed literature that describes the ecological-phytocenological areas in the country, and transparent information provided by forestry companies that manage area with small-, large- and silver-leaved linden forests, an analysis was performed in order to preliminarily suggest which forest company and under what conditions could be considered for potential feasibility study on mass linden production. In accordance with the natural habitat characteristics of the plant habitats and respecting the requirements of the species from the genus *Tilia*, which were described for the area of the former Socialist Federal Republic of Yugoslavia by the author Herman, and adding the findings of the linden research presented in the DBU.de report, which indicates a high degree of variability within and among linden populations, the recommendation of conducting wider research on establishing linden nursery for mass afforestation purpose in the future, in order to combat the negative consequences of climate change, could be given to Zavidovici-Teslic region (since natural conditions for growing linden in the nurseries already gave good results, as seen in the transparent information about nursery activity in the given company). It is interesting that the pollen maps of Europe, according to which linden pollen dominates in all habitats of the continent, raise a legitimate question whether linden cultivation in a nursery with various natural conditions in Bosnia and Herzegovina can result in quality linden trees that can adapt to all habitat conditions. Institutional support for the research of this possibility as well as various variants can be sought in the financing of scientific-research projects by forestry funds that belong to the Federal, that is, the Ministry in charge of forestry in the Federation of Bosnia and Herzegovina, and in the Republika Srpska Governmental institutions, that also could support scientific research and needed expertise. Areas such Una-Sana Canton also represents an interesting location for linden nurseries respecting the fact about existence of wider linden forest stand structures there, where the focus is on *T. tomentosa*. Successful production of *T. platyphyllos* in the Kupres, as seen from the website data collection of their active forestry company, gives hope that wider production of this species could be expected also in the future, with upcoming of higher temperatures and more frequent heat waves. Potential for further afforestation in Republika Srpska is giving optimism that the *Tilia* trees can provide better climate conditions for the local cities areas, what could result in the sustainable development of support of local forest management, forestry as industry and perseverance of local climate and biodiversity, as main fighter in mitigating climate change.

**SELECTION OF FOREST TREE SPECIES FOR SUSTAINABLE FORESTRY
PRODUCTION IN THE FUTURE - CASE STUDY: PRICE OF LINDEN PLANTING
MATERIAL AS A FACTOR IN AFFORESTATION SPECIES SELECTION**

Selma Vejzagić

A B S T R A C T

The article provides results on quantitative and qualitative analysis of data related to potential of linden trees to be used in the future as one of the commercial species in afforestation and plantations funding. Qualitative research of the forestry companies' bulletins in Bosnia and Herzegovina, consisting data on appearance of different, climate change process related pathogens, reveal real danger for the future of tree plantations in the country. In addition to this, a quantitative analysis on plantings price, as a potential decisive (limiting) factor in choosing commercial species for afforestation, was conducted. For the purpose of explaining behavior of the market prices relations of main competition - Oak and European beech wooden products, the linear regression function was used. Main results indicated clearly that the price of planting material is not and cannot be the limiting or crucial factor in deciding for the introduction of linden in the commercial forestry production in Bosnia and Herzegovina. Next results even in that, *that* the linden is more favored species when comparing duration of the production cycle, and that the species is less affected by diseases caused by climate change in comparison to Oak and European beech. Main linear regression results show that there is an extremely strong linear relationship between the prices of wooden products made from European beech and those made from Oak, suggesting the regression model is highly accurate and explains nearly all variations in oak wood prices based on beech wood prices. Approximately 40 scientific papers, books, reports, and forestry ministry related websites were used in aim to approach the problem and understand the importance of biology and ecology of the species in the context of forestry economic analysis related to prices on the market. The goal was to gather relevant data on the genus *Tilia*, its production potential, high immunity, resistance to negative effects of global warming, and the history of linden tree planting in Europe. This article is part of a broader interdisciplinary research project that combines forestry, forestry economics, forest ecosystem management, and city climate protection. The research results indicate that a careful planning strategy for future production, which must withstand climate change, is essential. This research is therefore designed as a foundation for future recommendations regarding linden research in the country. Linden, as a potential tree of the future and a species resistant to harmful environmental influences, could replace biomass that is threatened by the detrimental effects of deteriorating habitat changes, primarily in the form of soil drying in natural habitats and reduced efficiency in the production of commercial tree species such as oak and beech. In addition to its favorable effects on insects and the overall ecosystem, linden is also an attractive tree, with potential for carbon storage and broader use in furniture and construction timber production. Therefore, this article should serve as a guide for creative problem-solving techniques in the field of a large-scale production of industry wood.

Keywords: *Tilia*, linden, drought resistance, wood market, afforestation, commercial plantation, plant material price, limiting factor, quantitative analysis, qualitative analysis.

1. INTRODUCTION

Climate change threatens to jeopardize the sustainable economic flows of forestry as an industrial branch (Kumar, 2021). The need for the production of safe quantities of wood mass, as well as other forest products, is growing. Society, which includes numerous stakeholders who expect forestry companies to fulfill their requirements in terms of selling the highest quality wood mass in the shortest possible time, also demands respect for biological principles of forest management (Manrique & Franco, 2020). This means that forestry companies must pay attention to the sustainable use of forest resources, which are increasingly endangered by the harmful consequences of climate change, in their management of forests and valuable plant species, from the aspect of preserving the gene pool and biodiversity. Climate change threatens the local economy, especially in small and poor countries and developing countries, where the lack of statistical data is very often a problem (Mueller & Hofmann, 2022). Namely, having adequate sources of information is crucial for developing strategies for long-term afforestation (establishing forest tree cultures), which ensures continuity of production and market stability in terms of supply of forestry products (McHenry, 2012). According to the available information from the latest national inventory of forests on large areas in Bosnia and Herzegovina, the methodology of which was developed by experts from the Faculty of Forestry in Sarajevo, there are about one million hectares of areas in Bosnia and Herzegovina that currently do not have sustainable plant communities in terms of forest stands, and these areas are dominated by either bare land or land with low or poor vegetation (Lojo et al., 2008). Afforestation of large areas of land can have not only beneficial effects on the local economy, in terms of the future of forestry production at the level of smaller local communities, but can also have extraordinary and protective effects on the local climate, in terms of ensuring favorable temperatures in areas affected by intense drought, reduced levels of retained water and generally improving the local climate of cities. Of particular importance in the context of raising forest cultures is the participation of planting resistant tree species in drought in terms of maintaining populations of beneficial insects, which find shade and resources for life support in forest tree communities (Visnjic, 2002). This Paper will present information on the benefits of raising plantations in Bosnia and Herzegovina, in terms of supplementing forest production. The need for innovative solutions in climate change mitigation is becoming an imperative for today's forestry companies, which are increasingly cooperating with the academic community and taking into account the proposals and recommendations of forestry experts and scientists when it comes to plans for the future, sustainable monitoring of the health of forest stands, as well as calculating all possible challenges in terms of supplying society with an adequate amount of wood mass, without disrupting the balance of the ecosystem or worsening local climate conditions. The most important commercial tree species in Bosnia and Herzegovina include Oak (*Quercus sp.*), European beech (*Fagus sylvatica*), hornbeam (*Carpinus sp.*), white and black pine (*Pinus spp.*), Douglas fir (*Pseudotsuga sp.*), fir (*Abies sp.*), and spruce (*Picea sp.*), while many other species, such as noble broadleaf trees, are more respected in the sense of managing biodiversity, insects population viability, honey production, etc. (Mekic et al., 2006). One of the tree species with particularly unexplored potential for wider use in forestry is linden (*Tilia sp.*), which is prohibited for felling in certain parts of Europe, or its trees are extremely protected. However, this Paper will discuss the hidden potential of this species for wider use in the future, given the results obtained in recent years in the context of the genetics and distribution, or history, of this species. This paper will focus on a linear regression analysis, which should preliminarily illuminate the path for future research, in terms of the cost-effectiveness of considering linden as a tree of the future for the timber market in Bosnia and Herzegovina.

2.MATERIAL AND METHOD

2.1. Research Design and Study Area

The research is planned to include analyses of the prices between different seedling materials and identifying whether the density in planting plays an important role in choosing species for afforestation. Quantitative analyses should include interpretation of regression model usage in analyzing variations in prices of first-class wooden products of Beech and Oak, to check whether this model can be used in the future to identify rentability of mass production of higher number of Linden wood products (for furniture industry, construction etc.). In order to create a clear picture of the real impact of planting spacing (afforestation density) on the number of seedlings per hectare required for planting, and the relationship to the simple cost of planting (manual planting with a stick per individual seedling), only two-year-old linden, oak and beech seedlings will be taken into account, which would be planted on land of the same quality class (let's assume that it is the first quality class). Ignoring other factors that affect the increase in planting costs, which relate to soil preparation for planting, fertilizing seedlings, hoeing seedlings, removing weeds, thinning the culture, cutting branches and cleaning thickets, the Paper will focus only on approximating the picture of deciding on a particular tree species regardless of the price of seedlings and planting density, in relation to the benefits of planting that are potentially found in the length of the production cycle (Mekic, 2006). The reason for avoiding the unnecessary presentation of plantation establishment costs related to these activities lies in the fact that costs are calculated per hectare on a flat rate basis, regardless of whether in practice a worker working on an area of one-hectare processes, for example, 600 or 2000 trees during the performance of these tasks. It will not analyze the reasons for such a calculation in this Paper, but will base it on the price of seedlings. For the purpose of leading the discussion on gotten results, the following keywords are used in the search for scientific papers: 1) forest tree pathogens, 2) linden pathogens, 3) oak pathogens, 4) spruce pathogens, 5) tree mortality, 6) forest drying, 7) forest and climate changes, 8) sustainable forestry, 9) wood production challenges. The papers are obtained from: 1) ResearchGate, 2) Google Scholar and 3) Web site of Journal of Faculty of Forestry in Banja Luka. Other sources are: 1) Website of Federal ministry for forestry in Bosnia and Herzegovina and 2) Master plan of afforestation supported by the same type of Ministry office in the entity Republika Srpska. This paper should present the results of quantitative and qualitative analysis. Namely, in order to obtain a preliminary picture of the profitability of considering linden (*Tilia sp.*) as a tree of the future for planting plantations in Bosnia and Herzegovina, a **linear regression** analysis will be conducted, which will examine whether regression model is enough accurate and does it explains nearly all variations in Oak wood prices based on European beech wood prices. Price of linden seedlings can be a decisive factor in the choice of tree species for planting plantations. But if lower prices on linden wood produces articles that affects choice of tree species in afforestation, if the bonity class of the wood is same or similar, then regression model on comparing prices variations of potential wood products in the future could bring adequate results if compared to variations in Oak and European beech products. According to the previous knowledge of forestry companies, planting linden was abandoned and always resorted to planting beech, oaks, or coniferous tree species such as pines or spruce, not only because these are the most frequently planted tree species, but also because the prices of seedlings are favorable. However, this research design should also help in explaining how the price of linden seedlings relates to the prices of beech and oak seedlings and to allow making recommendations on future plantation plans funded on real benefits of planting linden (respecting climate change facts).

2.2. Research Objectives with Hypothesis

Considering that the Bosnian-Herzegovinian forest management is abandoning the planting of linden trees due to the discussable cost of linden seedlings, the aim is to investigate whether there is a basis for considering the price of planting material as a limiting factor for the selection of linden trees for cultivation, by comparing the prices of planting material, according to the average prices of seedlings in Bosnian-Herzegovinian nurseries (Govedar & Mataruga, 2021). In addition, the importance of linden tree cultivation is reflected in the possibility of introducing this tree as a substitute in the production of certain products (for example, wood for furniture, consumer wood) in which European beech and Oak have so far dominated. Taking into consideration that prices of wood products rise in accordance to wood quality class (European beech and Oak are considered to represent this class on the bosnian-herzegovinian market), it will be conducted the linear regression which should explain whether the regression model is accurate enough to explain nearly all variations (if possible) in oak wood prices based on beech wood prices. This should help to understand how the prices of wooden products of other species of trees (wood types) behave based on the bonity (quality wood based price for a first bonity of linden trees, and any other first class wood trees) (Cabaravdic, 2010). Considering that linden is a softer quality wood, it is necessary to conduct this preliminary research and consider the option of introducing linden wood into mass production, in order to timely start developing a future strategy for growing trees from substitute tree species for the current commercial tree species. Therefore, our goal is to investigate: 1) Does the price of linden (*Tilia sp.*) planting material represent a limiting factor for afforestation and establishment of linden plantations for the future, and does planting density or lack of knowledge of the species have more of an impact on not considering mass planting of linden in Bosnia and Herzegovina?, 2) Also, efforts will be made to determine whether there are dangers or risks to production in the context of climate change, in terms of pathogens emerging due to increased temperatures and the recurrence of forest fires in larger areas of forests and forest lands. Accordingly, the research hypothesis is tried to be proven, according to which:

H: *“The price of planting material is statistically not decisive for the choice of tree species for afforestation, what supports the regression model of wooden products prices trend in the context of prognosing rentability of linden products increase on the market.”*

2.3. Structure of the Paper

Structure of paper follows methodology that should approach advanced knowledge on interpreting qualitative and quantitative data supporting research hypotheses. In this case, the Paper focuses on analyses of real data in the real market conditions in Bosnia and Herzegovina, retrospectively to: 1) Market needs for wooden products, 2) Market prices of most important wooden articles sold, 3) Interpretation of further climate change correlated factors in sustainable production of biomass.

2.4. Data Collection

When considering the way of data collection, the next fact was taken into account: forestry logic assumes that deciduous tree species are planted on lands of those quality classes that correspond to more demanding deciduous tree species (what is in forestry known as first bonity class). Because of this, it was imagined to use relevant data showing real time prices of the planting material and wooden products in the real market in Bosnia and Herzegovina. It is also important to emphasize that the quantitative analysis will rely on the assumption that only the prices of two-year-old linden, beech and oak seedlings are taken into account in the calculations, while the cost of planting each individual seedling (manual planting with a stick) is calculated at 0.50 BAM per seedling. The data to be used in the quantitative analysis are taken from the planting and afforestation protocol from the

Afforestation Master Plan (Govedar and Mataruga, 2021), which is valid in Bosnia and Herzegovina, and mathematical calculations will be made regarding the number of seedlings per hectare, for three tree species: beech, oak and linden. The fixed price (cost) of manual planting with a stick will always be 0.50 BAM. Data on constant variables (tree species) and diverse variables (price of seedling, price of planting) will be entered into a “*Microsoft Excel*” table, where a regression analysis will be run. Data on the length of the *minimum*, *maximum* and *typical* production cycle duration will be taken from official guidelines in the field of Forest Management and Silviculture, for the conditions of Bosnia and Herzegovina (Lojo et al., 2008). Data related to prices of 100 different wooden products of Oak and Beech wood has been collected with the help of product bulletins of forest companies in Bosnia and Herzegovina, and their partners - different firms that are producing furniture, construction facilities and interior-exterior equipment. Regression analysis will be conducted in the “*Microsoft Excel*” (Cabaravdic, 2010). Part of the quantitative analysis which will consider the duration of the minimum, maximum and typical production cycle in beech, oak and linden forests, should be linked in a way of correlating results of a linear regression analysis on wooden products prices in Bosnia and Herzegovina, and also making a correlation to the qualitative analysis, but in a way that will try to explain how the influence of pathogens caused by climate change may play a role in deciding on the type of tree to be used in the establishment of plantations, that should in the same time represent one of the key factors in creating rentable prices of its wood products in the future.

2.5. Quantitative Analysis

Calculating the planting density (example given for *Tilia*) will be one of the first things to be done. It is worth noting that the number of seedlings per hectare is calculated as follows:

$$1 \text{ ha} = 10\,000 \text{ m}^2 \Rightarrow 10\,000 : (X \text{ m} * X \text{ m}) = \text{number of seedlings per 1ha}$$

E.g.: the density of linden planting is 2 m * 2 m, in this case:

$$10\,000 : (2 \text{ m} * 2 \text{ m}) = 2500 \text{ seedlings per 1ha (Mekic, 2006)}$$

In addition to these, results of the linear regression, graphically shown results (chart type) and tables will be presented in order to follow up testing prices variations of wooden products made in Bosnian Herzegovinian firms from Oak and Beech wood. The duration of the minimum, maximum and typical period of the production cycle of linden, beech and oak stands will be presented after calculating simple mathematical percentages, on how longer or shorter the production cycle of certain tree species relates to other commercial species.

2.6. Qualitative Analysis

Unlike the quantitative analysis, the qualitative analysis will determine the presence and type of pathogens that attack linden, oak and beech trees due to increased temperatures, evaporation of moisture from the soil and forest fires, and will describe how these pathogens may affect production in the future. The data used for the qualitative analysis will be collected from reports by forestry academic experts in Bosnia and Herzegovina (FMPVS.gov.ba), who have identified and confirmed which forest tree pathogens are involved, where they occur, in what way and what damage they cause to forest production. This data will be the result of a review of written sources of literature, available on the official websites of forestry companies and within the framework of the forest units' draft studies (document "Afforestation Plan" and document "Forest Protection Plan"). The qualitative analysis, which refers to the interpretation of the danger of forest fires and increased tree mortality due to the appearance of various pathogens, the spread of which is associated with the intensification of climate change, aims to provide a closer picture of the vulnerability of beech and oak in the future of forest production, in comparison to linden, which does not show symptoms of vulnerability that could lead to drying out, additional fragmentation or extinction.

3.RESULTS AND DISCUSSION

3.1. Review of the Literature with Main Theoretical Results

The annual permitted volume of cut timber in Bosnia and Herzegovina is slightly more than 7 million cubic meters. This timber is provided on an area of forests and forest lands of about 1.2 million hectares, where tall and coppice forest stands grow, most of which are located within the administrative borders of the entity of Republika Srpska (Lojo et al., 2008). Important guidelines for future production of forest timber and the establishment of plantations are contained in the so-called “Master plans for afforestation” of the Federation of Bosnia and Herzegovina and the Republika Srpska, which are written with the help of information from individual forestry companies from all over Bosnia and Herzegovina, which manage forests and plantations that are not privately owned. The results of the comparison of areas with high (generative origin) forests and wood stocks in the period between the two national inventories on large areas in Bosnia and Herzegovina show worrying phenomena. According to these data, the level of forest cover in Bosnia and Herzegovina has indeed increased compared to the period of the first national inventory of forests on large areas (1964-1968), and in the period of the second national inventory on large areas (2006-2009) there was an increase in the percentage of forest cover from over 50% to over 60% (Lojo et al., 2008). However, these are areas that have become overgrown with plant vegetation in rural areas after the population moved out due to the war in Bosnia and Herzegovina (1992-1995). Due to the abandonment of private estates and agricultural areas, mainly young plant communities have appeared, which, due to the slowing down of the population's return to their properties, have the potential to grow into larger forest complexes. The devastating fact of the analysis comparing the results of two forest inventories indicates a reduction in the area under high forests (forests of seed origin or short “generative origin”) by about one hundred thousand hectares. Although the number of residents in the country decreased due to increased population migration during the war and in the post-war period, due to the difficult economic situation, the needs of society as a whole for wood and forestry products are growing significantly from year to year (Mekic, 2006). Experts and students of the Faculty of Forestry in Sarajevo have been working on developing an application that can be used to report forest theft, which partially helps the process of monitoring the forest fund. A particular problem in the post-war forestry of Bosnia and Herzegovina is illegal logging, in which the leading trees are Oak, European beech, pine, spruce, fir, acacia, maple and ash, but also wild cherry, wild pear and walnut have not been spared either. The increase in prices of forest wood assortments on the market is dictated by the demand for commercial tree species, where volatility in the prices of beech and oak wood is observed in certain years, such as periods characterized by the occurrence of long-term droughts and the absence of fruiting in natural forests (Avdibegovic et al., 2007). European beech (*Fagus silvatica*), Oak (*Quercus sp.*), pine (*Pinus sp.*), Douglas fir (*Pseudotsuga sp.*), chestnut (*Castanea sp.*), walnut (*Juglans sp.*), fir (*Abies sp.*), spruce (*Picea sp.*), maple (*Acer sp.*), wild cherry (*Prunus sp.*), juniper (*Juniperus sp.*), poplar (*Populus sp.*) and willow (*Salix sp.*) continue to be the most attractive tree species, not only in afforestation, furniture production, firewood production (mostly oak, beech, hornbeam), veneer production, the establishment of parks and alleys, the establishment of flood protection belts in coastal areas (mostly poplars, willows), and other tree species are less emphasized in afforestation, and are mainly used in beekeeping, horticulture and landscaping private properties. Finding a solution for sustainable wood production in Bosnia and Herzegovina is of crucial importance in the context of climate change, especially taking into account that drought is endangering oak and beech forests, which poses linden as a drought resistant species in the focus of economic analysis.

3.2. Findings on Theoretical Results Explaining the Previous Research on Plantations Fundings to Secure Biomass for the Wood and Furniture Market

The history of planting tree plantations on larger areas in Bosnia and Herzegovina has not been sufficiently researched (Govedar and Mataruga, 2021). Certain oral data on the establishment of chestnut and linden plantations exist in the area of the Cajnice municipality in Bosnia and Herzegovina, the origin of which is linked to the expansion of the Austro-Hungarian monarchy in the territory of Bosnia and Herzegovina. In general, more intensive planting of trees for the needs of furniture production and additional quantities of wood began to take place during the 1920s, when certain studies or results of research on Bosnian and Herzegovinian forestry were already published in local documents. The exploitation of Bosnian and Herzegovinian wood during the annexation of the Austro-Hungarian monarchy in Bosnia and Herzegovina, in addition to exports to other parts of the monarchy, largely enabled the construction of roads, railways and other infrastructure in Bosnia and Herzegovina, and the planting of plantations took off mainly at the beginning of the 20th century (Mekic, 2006). However, during the 1960s, certain trends were also present in the former common state, the Socialist Federal Republic of Yugoslavia, when pine plantations became extremely popular. Namely, there was a great need for pine wood in Europe, especially in the northern European countries, and the production of furniture from coniferous wood experienced an expansion. The wood market in some countries promoted coniferous wood more than hardwood (f.e. Oak and European beech), but hardwoods still remained the focus of firewood production. Solid Oak and beech wood remained primarily in the wood products market for furniture production, and the sale of veneers “L” (glued veneer) and “F” (peeled veneer) became one of the most current topics of economic research by local forestry companies and wood processors and furniture manufacturers for homes, offices and schools. The most famous furniture company that buys and processes wood for the purpose of making extremely high-quality furniture is SIPAD (Avdibegovic et al., 2007) from Sarajevo, Bosnia and Herzegovina. The company employed tens of thousands of workers, and furniture was exported to many countries in Europe and the world. Depending on the hardness qualities of the wood, it is possible to make different objects or semi-products. Each forest area, which is characterized by the presence of large complexes of natural high forests, has certain tree species that can be called primary or dominant in these areas. The transport of wood over greater distances has greatly influenced the total costs of hauling and processing wood mass, and products made from this wood have certainly had a higher price. However, with the establishment of plantations in different areas, as well as by supplementing forest cultures, it is possible to reduce costs and thus influence the total price (Mueller and Hofmann, 2022). Certainly, the design of a strategy for mass afforestation in the future should be thoroughly analyzed and evaluated from various aspects, and one of them is finding a solution for selecting species that are estimated to have primacy in the future in the production of furniture and other products (DBU.de, 2021).

3.3. Theoretical Findings on Bosnian-herzegovinian Actual Issues Regarding Climate Change context

The biggest problem that arises for forestry in Bosnia and Herzegovina in the context of climate change is the drying of forests, both due to attacks by calamitous insects whose inoculums (centers of infection) appear after forest fires, and due to the drying of individual trees due to the complexity of the health status of trees (Andrianjar et al., 2021). Namely, the weakest trees in plant communities are usually the first to become infected with certain pathogens. Micro-localities of habitats that are affected by soil drying do not only become poorer in terms of reducing the amount of moisture in the soil, but the problem is also complicated by the evaporation of useful chemical elements and compounds from the soil. The evaporation of useful chemical elements from forest soil can ultimately

cause an imbalance in the proportions of organic and inorganic matter in the soil, which can result in a disruption in the development of vegetative and reproductive parts of plants. In addition to high air temperatures, the long-term absence of adequate moisture in the soil, and the occurrence of forest fires on large areas can irreversibly damage the habitat (primarily the quality of the soil, its chemical and physical properties) and even result in the succession of forest tree species. It is known that so-called pioneer tree species, such as those from the *Populus* and *Betula* genera, usually appear first on burned soils, which can only later, in the future, help improve the soil quality and repopulate previously existing tree species in that habitat (Kaul et al., 2010). Therefore, one of the challenges for forestry production is preserving the quality of soil in forest complexes and striving to improve the quality of forest soil, both through bio-technical measures of planting adequate tree species, removing (felling) infected trees, and through various land reclamation measures (depending on profitability, financial resources and goals of the forestry company) (Kumar, 2021). A special challenge in the context of forestry is the care of so-called honey-bearing species in forest ecosystems, which are important for biodiversity and the preservation of insect populations. An example of a honey-bearing species is linden (*Tilia spp.*), which is widely used in apiculture, which is based on beekeeping, honey production for the local and regional market with honey and products related to beekeeping, but also products that have a wide use in pharmacy and medicine (Kusiak et al., 2022). The honey market is one of the most important agricultural markets in Bosnia and Herzegovina, where honey has been traditionally used for centuries in everyday nutrition, alternative and official medicine (teas, tinctures, pharmaceutical raw materials) but also in gastronomy (sale of honey-related products in service industries), which is why linden is listed as one of the focus trees in planning future plantations on private properties (Bartsha, 1995., Barker et al., 2016, Barker et al., 2022). Finding also implicate appearance of pathogens on the forest species *Picea* (spruce wood), *Pinus* (pine wood), *Fagus* (beech wood) and *Quercus* (oak wood) which cause drying of the trees, what was in detail reported by Mekic (2006), who also named forest area around Vares as an example of pine forests drying. Something similar was spotted in the pine standings in the Konjic area (Ovcari), after the thermophilous pathogen *Viscum album* (white mistletoe) infected many trees. Exactly these pathogens, with some additional fungi and bacteria, cause increased mortality ratio.

3.4. Presentation of Quantitative Results

In this subchapter of the Paper, quantitative results will be presented first, followed by qualitative results. The quantitative results relate directly to the analysis of planting material prices and how the price of planting material of the commercially dominant species of beech and oak compares to the proposed substitute tree species, namely linden. The results will be immediately followed by a discussion, which should help clarify the results.

3.4.1.Context of Planting Density and How it Affects Species Choice

Analyzing data on recommended planting densities of forest tree species within the "Afforestation Plan" documents, which are an integral part of technical-technological (implementation) projects of forestry companies (which are part of broader *Forest Management Regulatory Studies*, which are adopted for a period of at least 10 years/10 years from the production period of the forest), the following results were obtained: **I.** - The recommended planting density for the European beech (*Fagus sylvatica*) tree species in Bosnia and Herzegovina is 4m x 4m, which means that the distance between neighboring beech trees is at least 4 meters in all directions, if maximum wood production is to be achieved with minimal damage to the physiological development of the trees, **II.** - The recommended planting density for the oak tree species (*Quercus petraea*) in Bosnia and Herzegovina is 3m x 3m, which means that the distance between neighboring oak trees is at least 3

meters in all directions, if maximum wood production is to be achieved with minimal damage to the physiological development of the tree. It must be noted here that in Bosnia and Herzegovina, two types of oak dominate in oak wood production, namely *Quercus petraea* (sessile oak) and *Quercus robur* (pedunculate oak). In cases where the soil is richer in water, pedunculate oak fits better into the production agenda, since it is a tree species that tolerates the presence of groundwater, wetland ecosystems and generally a higher percentage of moisture, without having negative consequences for the quality of the wood produced, **III.** - The recommended planting density of lime trees (*Tilia sp.*) is 2m x 2m, which means that the distance between neighboring lime trees is at least 2 meters in all directions, if maximum wood production is to be achieved with minimal damage to the physiological development of the trees. It is worth noting that three main types of lime trees grow naturally in Bosnia and Herzegovina, namely the small-leaved lime tree (*Tilia cordata*), the large-leaved lime tree (*Tilia platyphyllos*) and the silver-leaved lime tree (*Tilia tomentosa*). Since the silver-leaved linden tree, due to its habit, has the potential to occupy a larger space, and that, proportionally to its much larger leaves (compared to the small-leaved and large-leaved linden trees), it can absorb a higher concentration of CO₂ from the air and produce a larger wood mass, it is assumed that a higher planting density of 2m x 2m can be calculated in some other (future) analyses, even up to a planting density of 7m x 7m, which could greatly reduce the cost of purchasing planting material, which in that case becomes more than 300% more cost-effective (cheaper) compared to the cost of purchasing planting material if the planting density of 2m x 2m (which would be more suitable for the small-leaved linden tree) were to be maintained. Next table shows how the planting density relates between the three types of linden.

Table 1. Comparison between trees planting density among three suggested species.

Species	Planting Density	Trees per Hectare
Linden (<i>Tilia spp.</i>)	2 meters x 2 meters	2500
European Beech (<i>F. silvatica</i>)	4 meters x 4 meters	625
Oak (<i>Quercus spp.</i>)	3 meters x 3 meters	667

It is observed that, according to the given planting density, the most trees must be used to plant one hectare of forest land with quality planting material (2500 plants). Based on the mathematical relation (Mekic, 2010):

$$\text{Percentage increase} = \left[\frac{(\text{Number of linden trees} - \text{Number of beech trees})}{\text{Number of beech trees}} \right] \times 100$$

calculation arrives at the result of 300% more linden trees than beech trees, which are needed to plant one hectare of forest land. In general, guided by this planting density for all three tree species, it is observed that the most space is needed for the beech crown, and the least for the linden crown (graph 1).

Graph 1: Proportion of forest soil surfaces needed to handle the healthy tree crown area (in square meters) for each tree species.

The difference between the number of beech trees required in relation to the number of oak trees required for afforestation is not large, and amounts to 42 trees per hectare. This is 6.56% (with the value of $R^2 = 0.172$) more oak trees than beech. If we focus further on quantitative analyses, we will notice differences in the costs of purchasing oak, beech and linden seedlings, which can give us forests experts an idea of how the cost of purchasing seedlings can affect the choice of species for afforestation if the forestry engineer decides to establish a culture that would be of a mixed character, i.e., in which a certain percentage of linden, beech and oak trees would be planted. In forestry and in general in the establishment of plantations (cultures) of forest trees for the production of a wide range of wood products, cultures consisting of one species (so-called pure or monospecific tree cultures) and mixed cultures (multispecific forest tree cultures) can be established (Lojo *et al.*, 2008). Accordingly, a forestry engineer can influence the economic profitability and even save on the costs of establishing forest plantations. For example, if the density of linden planting (2m x 2m) is a major economic problem for a forestry company, because for afforestation or establishment of a culture consisting of linden trees, as much as 300% more plants need to be planted than if it were done only with beech (or oak), and the price of linden and beech seedlings is identical (0.50 BAM), while oak seedlings are somewhat more expensive (0.70 BAM). In order to establish a sustainable tree plantation from the aspect of climate change mitigation, a forestry engineer may propose, for example, a proportion of planting linden and beech together, in the ratio of 20% to 80%. In that case, 20% of the forest land area on one hectare would be planted (20% of the area of one hectare is 2000 m², which is divided by 4m² of space per linden tree crown) with linden seedlings, the purchase cost of which would be "500 linden seedlings * price of one seedling", and 500 beech seedlings would be planted (the remaining 80% of the area of one hectare is 8000 m², which is divided by 16m² of space per beech tree crown), which would make the total number of linden and beech seedlings in one mixed culture 1000. From the aspect of ecology and biology, and referring to dendrochronological research, i.e. the history of the settlement of European habitats by forest tree species, this proportion of species, i.e. their trees in the establishment of cultures, would have relatively sound foundations for the growth and development of a healthy and competitive mixed forest stand, because these are two species that can equally well thrive in a shared habitat (Mekic, 2006). What would be left for forest experts to consider is certainly the method of mixing, or rather, the mixing of trees (whether linden trees, which are fewer in number, would be planted individually or in groups next to beech trees, which are more numerous). Research into competition would be interesting for forest scientists, and perhaps a certain evolutionary pattern of behavior of these two species in the case of sharing a common space could be observed. If the recommendations of German experts (Heinrichs *et al.*, 2021), which were previously written for

the conditions of Romanian forestry, were to be accepted, that linden trees should be planted together with oaks on lands where there is potential for this, and in order to successfully mitigate climate change, the proportion of linden trees compared to the proportion of oak could be greater, and perhaps even equal to the proportion of oak. For example, if one adult tree (full form of developed crown) of linden requires 4 m², and one adult tree of oak (full form of developed crown) requires 9 m², then: **a.** - in scenario 1 (example) around ca. 30% of linden trees (3000 m² : 4 m² = 750) + 70% of oak trees (7000 m² : 9 m² = 777.77) comes to the figure of 1527.77 linden and oak trees for afforestation of one hectare, **b.** - in scenario 2 (example) around ca. 40% of linden trees (4000 m² : 4 m² = 1000) + 60% of oak trees (6000 m² : 9 m² = 666.66) comes to the figure of 1666.66 linden and oak trees for afforestation of one hectare, **c.** - in scenario 3 (example) around ca. 50% of linden trees (5000 m² : 4 m² = 1250) + 50% of oak trees (5000 m² : 9 m² = 555.55) comes to the figure of 1805.55 linden and oak trees for afforestation of one hectare. When taking into account, for all three reforestation scenarios according to the recommendations for Romania (Radoglou et al., 2009), the prices of planting material according to the Master Plan for Reforestation in Bosnia and Herzegovina, 0.50 BAM for linden and 0.70 BAM for oak, we arrive at the following results (graphs 2).

Graph 2: Costs for buying the total plant material for planting 1 hectare decreases with higher proportion of linden trees in the mixture proportions between linden-oak mixture scenarios.

To understand how the cost of buying trees aimed for funding a plantation changes, as the percentage of linden trees increases in the mixture, it is necessary to observe that in all the three scenarios linden trees take a new 10% of the total proportion (at the same time oak decreases equivalently). By adopting the second scenario, linden percentage increases:

$$40\% - 30\% = 10\%,$$

so for each 10% increase in the linden tree percentage, the cost increases by ca. 4.66% or 47,223 BAM (for value R² = 1.0). So, it can be observed that the mathematical relation:

$$\text{Percentage} = (\text{Cost increase} : \text{Total cost}) \times 100$$

(Lojo et al., 2008) was used.

However, the presented results of the mathematical analysis of percentages and proportions and the progressive growth of the cost of purchasing seedlings in all three scenarios remain the responsibility of the forestry engineer or forestry company, who should decide what the needs of society and stakeholders are in terms of the assortment, quantity and quality of wood products or plantations. Therefore, these three scenarios represent simple models for calculating the cost of purchasing seedlings if different models of mixed planting of forest tree seedlings were to be considered. It is worth noting that the prices of beech seedlings are lower than the prices of oak seedlings, and that one beech tree requires 16 m² of space compared to an oak tree that requires 9 m².

This would certainly significantly affect the cost of planting in terms of the cost of purchasing seedlings, but due to the lack of recommendations from current studies in Europe, scenarios for planting mixed beech and linden cultures are not considered, due to competition. Due to the past of Europe, which until the beginning of the Ice Age was characterized by large expanses of linden, whose habitats were taken over by linden after the cold snap, it is observed that linden pollen (Pigott, 2002, Klug *et al.*, 2000) is present everywhere. A justified research question arises as to whether linden planting material would enter into sharp competition with beech trees. On the other hand, there is already research indicating that the presence of linden in oak stands improves the growth of oak forests, which is why scenarios for planting mixed stands of linden with beech will not be considered in this Paper.

3.4.2. Prices of Individual Seedlings and Production Cycle Duration of Tree Species

In this case, a simple percentage calculation was performed, in order to investigate whether the price of the seedling itself statistically has a significant influence on the selection of the tree species for afforestation. Since the introductory considerations of the Paper state that the calculation is made with two-year-old seedlings of three broadleaf tree species that can equally grow and develop on land of the same quality and credit rating class, and that the price of seedlings taken from the Afforestation Master Plan (Govedar and Mataruga, 2021) in force in Bosnia and Herzegovina is the same for beech and linden (0.50 BAM) and slightly higher for oak (0.70 BAM), it will be analyzed whether the price of the seedlings themselves can statistically represent a decisive factor for the selection of the tree species. By comparing prices and durations of production cycles of Oak, Linden and Beech, we come to next results:

Graph 3: Trend of planting cost decrease (increase) in comparison to total number of trees planned in the afforestation of 1 hectare

By comparing it to the duration of production cycles among three species, we come to next graph:

Following the gotten data from Forestry Elaborate Methodology by Lojo *et al.* (2008), Linden plantations have shortest production cycle duration (60 years minimum, 100 maximum, 80 years typical), while beech is being planted for minimally 80 years, maximally 120 years and typically for

100 years. Having oak plantations being planted for minimally 100 years, maximally 200 years, and typically 150 years, Linden seems to be most rentable species for cultivating, with its minimal production period 100 percent shorter than beech typical production cycle duration and more than 300 percent shorter than maximal oak production cycle duration.

Graph 4: Trend of percentage increase in production cycle in three plant species.

3.4.3. Regression Analysis on Wood Article Prices of Beech and Oak in Bosnia and Herzegovina

By conducting the regression analysis in the “Microsoft Excel”, it came to the next results:

Table 2. Statistical analysis results on beech-oak prices in Bosnia and Herzegovina

Residual	99	82801.82501	836.3820708			
Total	100	47379425				
	<i>Coefficients</i>	<i>Standard Error</i>	<i>t Stat</i>	<i>P-value</i>	<i>Lower 95%</i>	<i>Upper 95%</i>

Intercept	0					
x	0.87686350	0.003687391	237.8004708	0	0.869546918	0.88418008

When explaining strength of the relationship, it is possible to observe next: a) Multiple R of 0.9991 means that the correlation coefficient is showing almost a perfect linear relationship, b) R^2 (R-squared) of 0.9983 is meaning that 99.83% of the variation in the dependent variable (oak wood prices) can be explained by the independent variable (beech wood prices), while c) Adjusted R^2 of 0.9982, as slightly lower than R^2 , is still very high, confirming the strong explanatory power of the tested model, which is similar to the Cabaravdic (2010) models explained in comparing deciduous and conifer species products for construction. Explaining the model significance by conducting ANOVA analysis means next: a) F-statistic of 56,549.06 is extremely high, indicating that the model is statistically significant, and b) Significance F (p-value) of 0 means there is almost no chance that the relationship is random, which compares to Avdibegovic (2007) statements for perfect forest market models. Explaining the regression coefficients it comes to next interpretations: a) Intercept of 0 means that the model does not include an intercept term (which means if beech prices were 0, oak prices would also be 0), b) Slope (x coefficient) of 0.8769 means that for every unit increase in beech wood price, the oak wood price increases by 0.8769, c) Standard Error of x coefficient of 0.0037 is pretty small, indicating a precise estimate, d) t-Statistic of 237.8 is very large, meaning the coefficient is highly significant, and e) P-value of 0 means that the predictor variable is highly significant. Explaining the model accuracy and residual analysis means next: a) Standard Error of 28.92 is the average deviation of the actual prices from the predicted prices, b) Residuals - most of them are small, but a few larger residuals (e.g., -78.35, 103.92) suggest possible outliers, and c) Normality of residuals shows in a way that they appear relatively small and balanced between positive and negative values, suggesting a good model fit., which again agrees with Cabaravdic (2010) findings in scope of explaining error values in the monograph. As a conclusion it came to next: 1) The used regression model is highly accurate and explains nearly all variations in oak wood prices based on beech wood prices, 2) The coefficient (0.8769) shows a strong proportional relationship, and 3) The residual analysis suggests minor outliers, but the overall fit is excellent.

3.5. Presentation of Qualitative Results

3.5.1. Identification of Main Pathogens in the Context of Planting Under the Droughts

On the basis of Federal Ministry office for forestry administration, based on the previous reports of the federal forestry companies, main illnesses affecting the sustainable production of Oak, Beech and Linden forests are: a) disease of grey leaf in Oak species, which causes drying and destruction of the oak plantations, b) disease of the black core in European beech, that devastate beech ecosystems and destroys complete plantations up to 90 percent of juveniles, and c) wilting disease in Linden, which appears as a result of combined natural and anthropogenic factors such as fertilization. The sources announced that mass drying of the beech and oak forests had been identified in certain parts of the country, but that it is still under control. Source announces no mortality cases in Linden. Compared to Kumar (2021) it is visible that forest pathogens represent everywhere in the world a real danger for forest production, because they combine with negative effects of wild forest fires in the large ecosystems and suppress natural juvenile populations to fight. Most of the diseases correspond to those described by Avdibegovic (2007), as main risks for the forestry firm's management. It is very important to point out to the wider academic community the importance of afforestation in the country, especially in those habitats where there is a potential for planting tree species that would be highly resistant to high temperatures and long-term droughts. Consideration of the price of planting material, possibly a large number of seedlings per hectare of area, as well as a smaller planting distance (density) should not be a decisive factor in limiting future cultivation, cultures (plantation) supplementation and afforestation to the most frequent tree species so far, but rather that it is necessary to give a chance to the application of current research results and the search for solutions for climate change mitigation. In this analysis, we should not lose sight of the harmful consequences of climate change, which includes an increased level of tree mortality in forests, and the appearance of pathogens and harmful insects, the spread of which is correlated with increased temperatures and the frequency of forest fires.

3.5.2. Knowledge Gaps in Understanding Potential of Healthy Linden Plantations in the Context of Drying Typical Commercial Species Such Oaks and Beech

A complex study of the morphological, phenological and genetic characteristics of three species of lime tree in Bosnia and Herzegovina has shown that the genus *Tilia* is very important for the process of climate change mitigation (Vejzagic et al., 2021). In earlier studies in Bosnia and Herzegovina, linden (in literature also named as “lime”) tree has been characterized as a tree of the future, due to its high resistance to drought, but also due to its distribution in almost all habitats where forests naturally grow. Certain linden tree populations in Bosnia and Herzegovina are characterized by different morphological characteristics of their fruits, which enable them to be dispersed by wind over greater distances, due to the greater number of bracts (Vejzagic, 2022). Linden trees were studied much more extensively on the European continent about 100 years ago, but the study of this tree finally intensified again in the 2010s. A major contribution to linden research and the analysis of pollen maps of Europe was made by the author Pigott, who pointed out the potential for linden to return to ancient habitats, since linden pollen is widespread throughout Europe, including in European forest habitats where linden currently dominates (Pigott, 1969, 1991, 1992, 1997, 2002). The onset of the Ice Age led to significant changes in the proportion of forest tree species in Europe, as well as to glacial retreats of entire plant populations (Klug et al., 2000). However, thousands of years later, researchers are witnessing an intensification of climate change, which brings with it high temperatures and long-term droughts, which necessitates the need for in-depth research on species that once, before the onset of the Ice Age, had primacy in forest plant communities (Logan et al., 2015). A great contribution to the study of linden, as well as its application in the establishment of plantations, the establishment of gardens, planting alleys and parks, was made by Scandinavian countries, followed by Germany, the Netherlands and the United Kingdom, where the largest number of studies on linden (Baxandall, 1995, Becker, 1920, Bengtsson, 2005, Binder, 2016, Christensen, 1981, De Jaegere et al., 2016, Engler,

1969, Huntley and Birks, 1983, Hyde and Williams, 1945, Karling, 1931, Lindberg, 1956, 1957, Svoboda, 1953, 1957, Wicksell and Christensen, 1999) come from. The potential of linden for planting in the future is supported in the deciduous forests of Europe, such as Romania, where it is possible to plant linden with oaks and beech (Heinrichs et al., 2021). A Ukrainian study has shown that linden trees are extremely long-lived and much more resistant to diseases and temperature turbulence. If seedlings costs and sustainable afforestation strategy are met, the potential of sustainable biomass production for future, including rentable prices of wooden products for society, the potential crisis on the wood market could be prevented. Unfortunately, negative reports on drying in the Oak and Beech stand structures are not bringing positive news to the wood and furniture market, which implies additional potential for the healthy linden plantations to be used more intensively in the future.

4.CONCLUSION

Respecting the quantitative and qualitative results gotten in the research, it is possible to identify several crucial findings: - forest species have to be chosen in scope of the afforestation lans not only on the fundament of expenses for buying seedlings or planting material, but also by respecting the benefits from planting cultures with drought resistant trees, - in comparison to first two commercial species in bosnian wood market, which are oak and beech, the linden tree can also be produces on a high bonity class soil, and with enough biomass produces in the cultures it an provide similar quality of certain wood products for the society, - lenght of the production cycle is crucial in the context of the climate change, because focusing on production of linden, whose minimal duration of the production cycle is more than 300 percent shorter than maximal oak production, can prevent drying of forest plantations caused by drought resistant pathogens, and help provide sustainable and production with less risk of drying, - regression model can be used to compare prices of same or similar quality wooden products of linden, since it is shown to be ideal in analyses of variation of prices between oak and beech products. Respecting the gotten results, we failed to reject the null hypothesis of the research that “*The price of planting material is statistically not decisive for the choice of tree species for afforestation, what supports the regression model of wooden products prices trend in the context of prognosing rentability of linden products increase on the market.*”. It is needed to conduct further investigation on the linden wood products market and to explore further danger for the linden plantation funding, if any indicators for the health of the species exist.

ABSTRACT

Inceptisols and Entisols each possess unique attributes concerning soil fertility. The management of these soils through appropriate agricultural practices such as the application of organic amendments, monitoring nutrient levels, and understanding soil texture and composition can play a crucial role in optimizing agricultural outputs. Given their moderate fertility levels, Inceptisols can be enhanced further through strategic fertilization, while Entisols, being less fertile, typically require more intensive management practices to improve their productivity. In summary, while both Inceptisols and Entisols present distinctive fertility profiles affected by their parent material and organic matter content, Inceptisols exhibit a greater potential for fertility improvements through management practices. This underscores the need for targeted soil management strategies to balance nutrient availability, particularly in areas where either soil type predominates.

Keywords: Inceptisol, entisol, soil properties, fertility

INTRODUCTION

Semi-arid climates are regions with limited rainfall and frequent dry periods. Semiarid climates are ecosystems where annual precipitation is mostly in the range of 300–600 mm. Inadequate water resources and high evaporation directly affect the physical and chemical structure of the soil. These effects lead to a decrease in organic matter, soil erosion, and mineral decomposition. Furthermore, soil with low water-holding capacity are common in these climates. Oxidation processes are frequent in the soil profile, threatening sustainable production. In Turkey, the semiarid zone is concentrated in Central Anatolia, Eastern Anatolia, and Southeastern Anatolia. Entisol and Inceptisol soils are

common in these regions. Inceptisols and Entisols are two significant soil orders that exhibit distinct characteristics influencing their fertility and agricultural potential. Understanding their fertility status is vital for effective land management, which is particularly critical in agricultural practices where nutrient availability directly impacts crop yield. In this review fertility status of inceptisol and entisol soils were discussed.

CHARACTERISTICS OF INCEPTISOLS AND ENTISOLS

Inceptisols are soils with limited horizon development, are pedologically young, and have low levels of mineralogical weathering (Soil Survey Staff, 2014). Inceptisols are generally young, underdeveloped soils and constitute approximately 17% of the world's land surface (USDA, 2014). The formation of these soils is shaped by the interaction of environmental factors such as climate, parent material, and vegetation. Inceptisols, which generally develop on alluvial sediments and in humid-temperate climates, are characterized by low carbonate content and neutral to slightly alkaline pH (Buol et al., 2011; Brady & Weil, 2010). Physically, these soils, which have a mostly loamy-sandy texture, exhibit good drainage. Clay content can range from 35–50%, which increases water retention capacity while limiting permeability (White et al., 2007). Inceptisols are generally rich in essential nutrients such as nitrogen, phosphorus, and potassium. However, organic matter levels vary depending on environmental conditions. Soil organic matter not only supports microbial activity but also enhances structural stability. These soils are densely populated by microorganisms such as bacteria, fungi, and protists. These organisms play an important role in humus formation and nutrient cycling (van der Heijden et al., 2008). The spatial distribution of different soil orders at the global scale is shown in Figure 1.

Figure 1. Global Classification of World Soils: A Mapping Focused on Entisols and Inceptisols (Eswaran and Reich, 2005).

Inceptisols are recognized for their relatively young and poorly developed profile, often featuring a significant horizon with minimal weathering. Inceptisol soils have poorly developed horizons and are generally characterized by stony and young profiles (Figure 2). They typically possess more nutrients compared to the more weathered Entisols, which are characterized by their young, unaltered state. Research has shown that Inceptisols, especially those studied in regions such as Aceh and Kerala, exhibit higher levels of critical nutrients such as nitrogen, phosphorus and potassium than Entisols, thereby presenting favorable conditions for crop production (Sharma., 2020; Nafiah & Prasetya, 2019). Vegetation improves soil physical structure by increasing organic matter accumulation through root release and detritus. Inceptisol soils have significant potential for sustainable agricultural production. However, they require careful land management due to limiting factors such as poor horizonization and salinity (Eswaran et al., 2003). The fertility status of these soils can be affected by various inputs, including organic fertilizers and mineral amendments. For instance, the application of biochar and other organic materials has been observed to increase soil organic matter and nutrient contents, resulting in enhanced fertility of Inceptisols (Kolambani & Widowati, 2022). Additionally, the use of vermicompost and microbial inoculants has shown promising results in improving the biological and chemical characteristics essential for plant growth (Lubis & Sebayang, 2024; Mukhtar et al., 2023). Conversely, Entisols are characterized by lower fertility owing to their relatively young profiles and minimal horizon development. They often exhibit coarse textures leading to high infiltration rates and low water retention ability, which considerably limit their productive capacity (McLeod et al., 2021). Despite these challenges, studies indicate that Entisols can be improved through the application of biofertilizers, mycorrhizal associations, and organic amendments that enhance nutrient availability for crops like patchouli (Syafuruddin et al., 2022). Furthermore, Entisols show variable fertility depending on their parent material, with certain instances indicating that alluvial Entisols can be quite fertile, while those on steeper slopes or sandy areas tend to have low productivity due to low organic matter accumulation (Syafuruddin et al., 2022). In terms of micronutrient dynamics, both soil types exhibit distinct mobility patterns for heavy metals. For example, the mobility factor of nickel (Ni) is higher in Inceptisols compared to Entisols, which demonstrates their differing capacities to retain and mobilize various elements based on their mineralogical and chemical nature (Patra et al., 2021). Additionally, while Entisols might have deficiencies in certain macronutrients, some studies report higher mobility for specific micronutrients like zinc (Zn) in different land use systems, highlighting the need for careful management to mitigate nutrient deficiencies in both soil types (Gowthamchand et al., 2023). Entisols are young and underdeveloped soils; they have low organic matter content and are susceptible to erosion. Inceptisols, on the other hand, contain more organic matter in the upper horizons and are structurally more developed (Türkeş, 1999). Entisols are young soils that do not show significant horizon development (Figure 3).

Figure 2. General view of inceptisol soil (<https://www.nrcs.usda.gov/conservation-basics/natural-resource-concerns/soil/inceptisols>).

Figure 3 General view of entisol soil (<https://www.nrcs.usda.gov/conservation-basics/natural-resource-concerns/soil/entisols>)

NUTRIENT AVAILABILITY AND MANAGEMENT STRATEGIES

Despite their generally favorable fertility, Inceptisols often face challenges related to nutrient management, primarily nitrogen deficiencies (Rizwan & Harahap, 2022). Studies indicate that the addition of both organic and inorganic fertilizers, along with balanced nutrient management strategies, can significantly improve the chemical characteristics of Inceptisols, increase crop yields, and reduce reliance on synthetic fertilizers (Rizwan & Harahap, 2022; Lubis & Sebayang, 2024). For instance,

the application of combinations of organic fertilizers such as chicken manure has been found to effectively enhance the fertility of Inceptisols (Rizwan & Harahap, 2022; Kolambani & Widowati, 2022).

Moreover, findings from Corrêa et al. indicate that fluid mineral fertilizers can be particularly effective for increasing carbon stock and optimizing soil nutrient dynamics in Inceptisols due to their relatively lower degree of weathering compared to more developed soils (Corrêa et al., 2019). Therefore, integrating different fertilization methodologies can significantly impact the nutrient profile, leading to enhanced agricultural productivity (Lubis & Sebayang, 2024, Ghosh & Debnath, 2010).

CONCLUSION

Semiarid climate regions present special challenges in terms of soil fertility due to environmental factors such as low and irregular rainfall regime, high evaporation rate and limited water resources. Entisol and Inceptisol soils are commonly found in this climate zone. In order to ensure sustainable agricultural production, it is necessary to develop appropriate management and reclamation strategies for these soils. Increasing soil organic matter, reducing erosion, and improving water management are among the keyways to increase productivity, particularly in Entisol-characterized lands. In Inceptisol soils, integrated land management practices are gaining importance for the preservation and sustainable use of existing potential. Furthermore, a combined evaluation of national and international soil classification systems demonstrates the need for combined use of multi-source data to map and manage soil diversity in Turkey. Consequently, the accurate classification, monitoring, and management of Entisol and Inceptisol soils in semiarid conditions is a scientific and strategic necessity for establishing sustainable agricultural policies.

ABSTRACT

Natural antioxidants are gaining increasing importance in functional food and pharmaceutical applications. *Elaeagnus umbellata* fruit is rich in phenolic and flavonoid compounds and has high antioxidant potential. In this study, the effect of water content (%), lactic acid/choline chloride ratio, and temperature (°C) factors on antioxidant capacity was analyzed using DPPH (2,2-diphenyl-1-picrylhydrazil) radical scavenging capacity, FRAP (Ferric Reducing Antioxidant Power), TPC (Total Phenolic Content) and TFC (Total Flavonoid Content) analyses, and optimized using Response Surface Methodology (RSM). The results of the analyses showed that the highest antioxidant activities were obtained at a water content of 28.28 %, a lactic acid/choline chloride ratio of 3, and a temperature of 70 °C. Under these conditions, DPPH, FRAP, TPC, and TFC values were measured as 6.51 mg TE/g, 21.88 mg TE/g, 23.09 mg GAE/g, and 4.15 mg QE/g, respectively. The results indicate that phenolic and flavonoid compounds are temperature-sensitive and that optimal extraction occurs at medium-high temperatures. Furthermore, FRAP and DPPH analyses confirm that the extract possesses high free radical scavenging and reducing capacities. This study demonstrates that *E. umbellata* fruit is a potent natural antioxidant source under optimized conditions and can be used in functional food and pharmaceutical applications.

Keyword: *Elaeagnus umbellata*, Antioxidant activity, Optimization,

INTRODUCTION

Medicinal plants have been used for both food and therapeutic purposes throughout history in various civilizations (Jamshidi-Kia et al., 2017; Bhat et al., 2023). *E. umbellata* Thunb., a plant commonly found in the Northwestern Himalayas, is notable for its rich bioactive compound content (Chauhan et al., 2023; Bhat et al., 2023). It is also widely used in traditional medicine for its antioxidant, antimicrobial, anti-inflammatory, anticancer, and antidiabetic effects (Nazir et al., 2021). Today, research on the effects of consuming natural compounds on human health has increased, and it is crucial to better understand the potential of plants such as *Elaeagnus umbellata*. *E. umbellata* holds significant potential for the pharmaceutical and functional food industries due to its broad bioactive compound profile. Current studies support the protective and therapeutic effects of this plant against diseases, but emphasize the need for more detailed investigation of the mechanisms of its active compounds.

The fruits of *E. umbellata* are rich in polyphenols and anthocyanins with high antioxidant capacity (Ozen et al., 2017), and the plant's fruits and leaves also contain high amounts of polyphenols, flavonoids, carotenoids, alkaloids, and saponins (Khattak, 2012). Therefore, they provide protection against free radical damage and play a role in preventing diseases associated with oxidative stress (Nazir et al., 2021; Bhat et al., 2023). Additionally, the flavonoids and phenolic compounds found in the plant support the immune system by exhibiting anti-inflammatory effects (Bhat et al., 2023). Furthermore, its high lycopene content suggests that this plant could be an important resource in the prevention of cancer and cardiovascular diseases (Patel, 2015; Ozen et al., 2017). Pharmacological studies have revealed that *E. umbellata* possesses anticancer activity, particularly that ellagic acid components may inhibit tumor growth (Vignera et al. 2022). Furthermore, studies have shown that *E. umbellata* extracts lower blood glucose levels in diabetic models, and that this effect is related to the inhibition of free radicals by the phenolic and flavonoid compounds it contains and the increase in insulin sensitivity by suppressing the α -glucosidase enzyme. (Nazir et al. 2018).

In this study, the effects of ultrasonic power, extraction time, and sample amount on the DPPH radical scavenging capacity, FRAP, TPC and TFC of *E. umbellata* fruit extracts were investigated. The results obtained using RSM reveal the significant effects of these variables on antioxidant properties.

MATERIAL AND METHOD

Material

The fruits of *Elaeagnus umbellata* were obtained from local producers in Trabzon, Türkiye. They were dried at 50 °C until a constant weight was achieved. The dried samples were ground using a mortar and subsequently used for extraction. All chemicals employed in the study were purchased from Sigma.

Extraction

The extraction procedure was performed with modifications based on the method described by Alishlah et al. (2019). For extraction, 1 g of sample was weighed into 50 mL falcon tubes, followed by the addition of 20 mL of the prepared DES solutions at the ratios specified in the experimental design. The mixture containing the sample and solution was then placed in an ultrasonic water bath (20% ultrasonic power) for 30 min, considering the temperature parameters defined in the experimental design. After the incubation period, the samples were centrifuged at 3500 g for 45 min. The supernatants were collected and filtered using coarse filter paper. The prepared extracts were stored at -20 °C until further analysis.

Experiment design and optimization

Experimental conditions were established using the Box–Behnken response surface methodology, with the experimental design generated using Minitab 18.1 software (Table 1). Extraction was performed according to the procedure described in the "Extraction" section. The extracts were evaluated for TFC, DPPH, FRAP, and TPC which were employed as response variables to optimize extraction efficiency.

Three independent factors were investigated: water content (20–40%) (X1), molar ratio (lactic acid/choline chloride, 1–3) (X2), and temperature (30–70 °C) (X3). A total of 15 experimental runs were implemented under these conditions. Statistical analyses were carried out at a significance level of $P < 0.05$, and the adequacy of the extraction model was assessed using analysis of variance (ANOVA).

Table 1. Experimental variables based on water content, temperature, and molar ratio

Water content (%)	Molar ratio (lactic acid/choline chloride)	Temperature (°C)
40	2	30
20	2	30
30	1	30
30	3	30
30	2	50
40	3	50
40	1	50
30	2	50

20	1	50
30	2	50
20	2	70
40	2	70
30	1	70
30	3	70

DPPH radical scavenging activity assay

The decrease in optical density was associated with DPPH radical uptake. For analysis, 100 μ L of the ethanol extract was mixed with 2000 μ L of 0.2 mM DPPH solution, vortexed, and incubated for 30 min at ambient temperature. The absorbance was then recorded at 517 nm, and the results were expressed as Trolox equivalents (mg/g) (Kumaran and Karunakaran, 2007).

Ferric reducing antioxidant power assay

A fresh FRAP working solution was prepared by mixing 25 mL of acetate buffer, 2.5 mL of TPTZ solution, and 2.5 mL of $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ solution from the stock reagents. The mixture was preheated to 37 °C prior to use. Subsequently, 150 μ L of the extract (0.1 mg/mL) was reacted with 2850 μ L of the FRAP reagent for 30 min in the dark. The formation of the ferrous–tripyridyltriazine complex was quantified at 593 nm, and the results were expressed as mg Trolox equivalents per g of sample (Upadhyay et al., 2010).

Total phenolic content

The TPC of the extract was quantified using the Folin–Ciocalteu reagent following the procedure described by Gülcin et al. (2002). Briefly, 0.1 mL of the extract was diluted with 46 mL of distilled water in a volumetric flask. Subsequently, 1 mL of the Folin–Ciocalteu reagent was added, and the mixture was thoroughly mixed. After a 3-min incubation, 3 mL of 2% Na_2CO_3 solution was introduced, followed by intermittent shaking and a 2-h resting period. Absorbance was recorded at 760 nm, and the results were calculated based on the gallic acid calibration curve and expressed as mg gallic acid equivalent (GAE)/g.

Total flavonoid content

The aluminum chloride colorimetric method was employed to determine the flavonoid content of the fruit extracts. In this assay, 1 mL of the ethanol-diluted sample was combined with 1 mL of 2% AlCl_3 in methanol. Following a 15-min reaction period, absorbance was recorded at 430 nm. Flavonoid content was calculated using a calibration curve prepared with quercetin standards of known concentrations, and results were expressed as mg quercetin equivalents (QE) per g of sample (Djeridane et al., 2006).

RESULTS AND DISCUSSION

Effect of experimental conditions on TPC, TFC, FRAP and DPPH

According to the DPPH radical scavenging capacity results, the lowest and highest values were recorded as 1.33 mg TE/g and 6.42 mg TE/g, respectively. According to the ANOVA results, the model was found to be highly significant ($P < 0.05$), with $R^2 = 97.50\%$. The highest DPPH values were observed in combinations of high temperature levels, medium-high water content, and medium lactic acid/choline chloride ratios. In contrast, the lowest DPPH values were recorded at low temperature, low water content, and low lactic acid/choline chloride ratio levels. The combined increase in water content and temperature factors created a general upward trend in DPPH values. Similarly, the quadratic effect of the lactic acid/choline chloride ratio contributed to an increase in antioxidant capacity at certain levels. Furthermore, the interaction between water content and temperature factors was found to be statistically significant ($P < 0.05$), indicating that optimal antioxidant activity can be achieved under certain combinations (Figure 1).

Figure 1. Variation of DPPH with independent variables Water content–Molar ratio (A), Water content–Temperature (B), and Molar ratio–Temperature (C). Water content (X1, %), Molar ratio (X2, lactic acid/choline chloride), and Temperature (X3, °C).

FRAP analysis revealed values ranging from 7.67 mg TE/g to 22.27 mg QE/g. Statistical analysis via ANOVA indicated that the model was significant ($P < 0.05$), with a coefficient of

determination (R^2) of 91.97%. The highest FRAP responses were achieved under conditions of elevated temperatures, medium-high water content, and medium lactic acid/choline chloride ratios. Conversely, the lowest FRAP values were associated with low temperature, low water content, and low lactic acid/choline chloride ratios, highlighting the strong influence of these extraction parameters on antioxidant activity. The combined increase in water content and temperature has created a general upward trend in FRAP values. Similarly, the quadratic effect of the lactic acid/choline chloride ratio has contributed to an increase in antioxidant capacity at certain levels. However, raising the temperature to very high levels has caused a decrease in FRAP values beyond a certain point (Figure 2).

Figure 2. Variation of FRAP with independent variables Water content–Molar ratio (A), Water content–Temperature (B), and Molar ratio–Temperature (C). Water content (X1, %), Molar ratio (X2, lactic acid/choline chloride), and Temperature (X3, °C).

In terms of total phenolic content, the lowest value was 11.20 mg GAE/g, while the highest value was 24.09 mg GAE/g. According to the ANOVA results, the model was found to be significant ($P < 0.05$), and $R^2 = 92.42\%$ was calculated. The highest TPC values were observed in combinations of high temperature levels, medium-high water ratio, and medium lactic acid/choline ratio. In contrast, the lowest TPC values were recorded at low temperature, low water ratio, and low lactic acid/choline chloride ratio levels. The quadratic effect of the lactic acid/choline chloride ratio contributed to an increase in the TPC value, while the quadratic effects of the water ratio and temperature showed a downward trend in the TPC value at certain levels. Furthermore, the two-way interactions between the factors produced measurable changes but were not statistically significant (Figure 3).

Figure 3. Variation of TPC with independent variables Water content–Molar ratio (A), Water content–Temperature (B), and Molar ratio–Temperature (C). Water content (X1, %), Molar ratio (X2, lactic acid/choline chloride), and Temperature (X3, °C).

In the total flavonoid content analysis, the lowest and highest values were determined to be 2.81 mg QE/g and 4.27 mg QE/g, respectively. According to the ANOVA results, the significance level of the model was borderline ($P > 0.05$), and R^2 was calculated as 87.49%. The highest TFC values were observed in combinations of high temperature levels, medium-high water ratio, and medium lactic acid/choline ratio. In contrast, the lowest TFC values were recorded at low temperature, low water ratio, and low lactic acid/choline chloride ratio levels. The interactions between moisture content and temperature, and between lactic acid/choline chloride ratio and temperature contributed to changes in TFC values. Additionally, the quadratic effect of water ratio and lactic acid/choline chloride ratio showed a tendency to decrease TFC values at certain levels. These results are consistent with the significant positive effect of temperature on TFC (Figure 4).

Figure 4. Variation of TFC with independent variables Water content–Molar ratio (A), Water content–Temperature (B), and Molar ratio–Temperature (C). Water content (X1, %), Molar ratio (X2, lactic acid/choline chloride), and Temperature (X3, °C).

In general, the combined increase in water content, lactic acid/choline chloride ratio, and temperature factors has led to an upward trend in antioxidant and phenolic content across all analyses. Specifically, combinations of high temperature and medium-to-high water content have resulted in maximum values. However, exceeding certain levels has caused a decrease in some parameters, highlighting the importance of optimal conditions.

Optimization Results and Factor Effects

In this study, the antioxidant capacity of extracts obtained from *E. umbellata* fruit was evaluated using FRAP, DPPH, TPC, and TFC analyses, and the extraction conditions were optimized using RSM.

The analyses showed that the optimal antioxidant responses were obtained at a water content of 28.28 %, a lactic acid/choline ratio of 3, and a temperature of 70 °C. Under these optimized conditions, the model predicted values of 6.51 mg TE/ g for DPPH, 21.88 mg TE/ g for FRAP, 23.09 mg GAE/ g for TPC, and 4.15 mg QE/ g for TFC. The corresponding experimental values were 6.45 mg TE/ g (DPPH), 21.50 mg TE/ g (FRAP), 22.55 mg GAE/ g (TPC), and 4.05 mg QE/ g (TFC), indicating a strong agreement between the predicted and experimental data. These results, supported by high R^2 values and narrow confidence intervals, demonstrate the model's strong predictive ability and reliability.

The DPPH radical scavenging capacity (6.51 mg TE/ g) and FRAP value (21.88 mg TE/ g) obtained indicate the extract's high free radical scavenging potential and strong reducing power. These values are close to the upper limit of the target range set at the beginning of the study and demonstrate that the optimization of antioxidant activity has been successfully achieved.

Additionally, these results indicate that both total phenolic and flavonoid compounds are temperature-sensitive, and optimal extraction occurs at medium-high temperatures. In particular, the

high TPC values indicate that the plant's polyphenolic structure can be extracted with maximum yield at around 70 °C. This supports the notion that phenolic compounds exhibit a certain heat resistance, but that excessive temperatures can cause degradation.

Additionally, it has been emphasized that extraction parameters (particularly temperature and solvent ratios) play a critical role in the yield of these compounds (Spigno et al., 2007; Mokrani and Madani, 2016; Shi et al., 2022). The literature reports that *E. umbellata* fruits extracted using 80 % ethanol have phenolic contents ranging from 1037–1260 mg GAE/100 g dry matter and possess strong antioxidant activity (Roscha et al., 2023). Similarly, Khattak (2012) reported the phenolic content of *E. umbellata* fruits to be 23.3 mg GAE/g and the flavonoid content to be 3.6 mg QE/g on a dry weight basis. The predicted values obtained from the model (DPPH: 6.45 mg TE/g, FRAP: 21.50 mg TE/g, TPC: 22.55 mg GAE/g, and TFC: 4.05 mg QE/g) were found to be highly consistent with the experimental data, further confirming the reliability and predictive accuracy of the optimization model. These findings indicate that the applied DES-based ultrasonic extraction conditions effectively yield phenolic compounds and that *E. umbellata* fruit is a potent natural antioxidant source.

This study has demonstrated that the antioxidant capacity of extracts obtained from *E. umbellata* fruit can be significantly increased under optimized extraction conditions, indicating that it could serve as a valuable natural antioxidant source for functional food and pharmaceutical formulations.

CONCLUSIONS

This study has demonstrated that ultrasonic extraction parameters play a critical role in enhancing the antioxidant properties of extracts obtained from *E. umbellata* fruit. Under conditions optimized using RSM, it was determined that total phenolic and flavonoid compounds, as well as DPPH and FRAP values, were obtained at maximum levels. In particular, the results obtained at around 70 °C show that polyphenolic structures can exhibit high stability at certain temperature ranges, but excessive temperatures can lead to degradation. The data obtained indicate that *E. umbellata* fruit can be evaluated as a powerful natural antioxidant source in functional food and pharmaceutical product development studies; it also provides a scientific basis for sustainable and healthy product design.

ABSTRACT

The objective of this study is to analyze the potential of a rainwater harvesting (RWH) as an alternative water source for the industrial sector. The table olive industry was chosen for this analysis, with two distinct companies, Firm I and Firm II, serving as case studies. Firm I, with an annual production capacity of 1350 tonnes of natural black, black, and green olives, has a roof area of 2333 m². Annual water consumption is calculated to be 8797 m³ while the total harvestable rainwater is approximately 1250 m³. Based on these figures, it is estimated that RWH could meet 15% of Firm I's total water requirements. Firm II produces 1500 tonnes of natural black olives annually and has a larger roof area of 2885 m². The annual water consumption is 2419 m³, which is less than Firm I due to its smaller-scale, natural olive production profile. The annual harvestable rainwater is calculated as 1718 m³. Thus, the runoff available from the rooftop of Firm II is insufficient to meet the annual water demand. However, the harvested rainwater can still supply approximately 70% of the firm's total water requirements. The results revealed that rainwater harvesting will not be sufficient to meet all the water requirements of the facilities examined, but it can provide significant water savings.

Keywords: Rainwater harvesting, Water reuse, Water scarcity, Table olive industry, Precipitation,

INTRODUCTION

Rainwater harvesting (RWH) is a viable solution for water scarcity, offering benefits such as an additional water supply, flood mitigation, and a reduced environmental footprint (Oral et al., 2025). While its success is well-documented in urban settings like office buildings, schools, and supermarkets, its use in industry remains limited. However, harvested water is suitable for a variety of industrial uses, including process water, cooling water, garden irrigation, and firefighting (Bayırtepe and Dolgen, 2024). Using harvested rainwater for non-potable purposes can significantly reduce a company's reliance on municipal water supplies, leading to lower water costs. Furthermore, rainwater's natural softness and lack of chemical additives make it ideal for many applications, including irrigation and toilet flushing. Implementing RWH also enhances a company's sustainability profile and corporate social responsibility, which can improve its reputation among environmentally conscious consumers and stakeholders.

A typical rainwater cistern system (RWCS) consists of four basic components: a collection (catchment) area, a conveyance system, storage, and treatment facilities (Dolgen et al., 2006). The most common collection area is a building's roof, though open fields can also be used. The efficiency and quality of collected water are influenced by the roof's effective area and construction material.

While any roofing material is acceptable for non-potable uses, water intended for drinking should not be collected from roofs with asphalt shingles, and lead flashing should be avoided. The conveyance system, typically composed of gutters and pipes, transports rainwater from the roof to storage. Both pipes and roof surfaces should be made of chemically inert materials, such as wood, plastic, aluminum, or fiberglass, to prevent water contamination (Thomas and Martinson, 2007). Water is ultimately stored in a cistern or tank, which should also be constructed from an inert material like reinforced concrete, fiberglass, or stainless steel. Storage tanks can be integrated into a building's structure or built as a separate unit. They are commonly designed as surface or above-ground tanks for roof collection and as sub-surface or underground tanks for ground catchment systems. The storage capacity of the cistern is a crucial design factor. Insufficient capacity can lead to water shortages during low-rainfall periods, while excessive capacity can increase construction and operating costs, potentially making the system economically unfeasible. To promote the use of RWH technology, governments can play a vital role. This includes offering financial incentives to users and establishing standards and codes for the construction, operation, and maintenance of these systems to ensure public health and safety.

This paper evaluates the potential for RWH in the olive sector in Türkiye. This focus is justified because: (i) olive oil and table olives are important Turkish products, (ii) olive farming is widespread in water-stressed regions of Türkiye, such as the Aegean, Marmara, and Southeastern Anatolian regions, and (iii) olive harvesting and processing periods coincide with high precipitation. To conduct this analysis, two table olive production companies in the Manisa-Akhisar region of Türkiye is chosen as a case study. Data on water consumptions are obtained from the companies. Precipitation data is provided from the Turkish State Meteorological Service. The volume of the harvested rainwater from a rooftop is calculated considering the roof surface area, the average rainfall, and a runoff coefficient that accounts for system efficiency. And, results are discussed considering the water consumption and harvestable rainwater volumes, potential uses and barriers to adopt RWH systems.

MATERIAL AND METHOD

Study Area

The study was conducted in Akhisar, a town in the southwestern region of Türkiye known for its high production of green, black, and natural black olives. This area was selected for analysis because the Akhisar is known for its intensive olive farming. The research focused on two distinct companies, Firm I and Firm II, both of which are located within the Akhisar Olive Specialized Organized Industrial Zone (AZIOSB).

Figure 1. Location of the Akhisar Olive Specialized Organized Industrial Zone (AZIOSB)

This zone, a strategic development, consists of over one hundred factories with varying sizes and production capacities. The geographic location of the examined factories is illustrated in Figure 1. Firm I, with an annual production capacity of 1350 tons of natural black, black, and green olives, has a roof area of 2333 m². Firm II produces 1500 tonnes of natural black olives annually and has a larger roof area of 2885 m².

Rainfall Analyses

The study utilized 94 years of monthly rainfall data (1930–2024) for the Manisa province, obtained from the Turkish State Meteorological Service. The analysis, summarized in Table 1, shows that the region receives an average annual rainfall of 743.8 mm over an average of 86.2 rainy days. As Table 1 illustrates, rainfall is at its highest in December, with 137.5 mm, while August receives the lowest amount, with 9.3 mm.

Table 1. The precipitation data for the Manisa Province

Month	Average Number of Rainy Days	Average Monthly Total Rainfall (mm)
January	13.23	127.4
February	11.11	108
March	9.89	77.8
April	8.96	55.1
May	6.76	38.9
June	3.39	20
July	1.05	9.7
August	0.83	9.3
September	2.28	19.4
October	5.72	51.8
November	9.42	88.9
December	13.57	137.5
Annual	86.2	743.8

Calculation

In the presented study, the volume of the harvested rainwater from a rooftop is calculated considering the roof surface area, the average rainfall, and a runoff coefficient. The basic formula given in the below was used in the calculations.

Volume of the harvestable water = Catchment area (m²) x Annual rainfall (mm) x Runoff Coefficient

In the study, the roof top areas for Firm I and II was obtained from the company. Rainfall data obtained from the Turkish State Meteorological Service. Runoff coefficient which is a factor ranged between 0 and 1 consider the water loss due to evaporation, leaks, splash-over, and the material of the roof. For example, a smooth metal roof has a high runoff coefficient (often 0.9 or 0.95), while a more porous surface like asphalt shingles or a flat cement roof might have a lower coefficient (0.6 to 0.8). In the examined factories the roof material was metal therefore high runoff coefficient (i.e. 0.9) was used.

RESULTS AND DISCUSSION

The study analyzed the potential for rainwater harvesting at two firms, with rooftop areas of 2332 m² (Firm I) and 2885 m² (Firm II). Monthly harvestable rainwater volumes were calculated based on a formula detailed in the materials and methods section. To evaluate the feasibility of this water source, the firms' monthly water consumption data were also collected. A comparison of these two datasets for Firm I, shown in Figure 2, reveals that monthly water consumption consistently surpasses the available volume of harvested rainwater. The highest water consumption occurs in October, which is attributed to the beginning of the olive fruit collection season. The difference between water consumption and harvestable rainwater is significant due to very low precipitation during the summer. Annual water consumption is calculated to be 8797 m³ while the total harvestable rainwater is approximately 1250 m³. Based on these figures, actually, the runoff available from the rooftop of Firm I is insufficient to meet the annual water demand. Only the 15% of the total water requirement can be obtained from the rainwater. On the other hand, the monthly water consumption exceeding the harvestable rainfall also means that a smaller storage tank capacity could be sufficient which makes the investment economically feasible.

Figure 2. Water consumption and potential for harvesting rainwater at Firm I

Figure 3 shows Firm II's water consumption and harvestable rainwater data. The annual water consumption is 2419 m³, which is less than Firm I due to its smaller-scale, natural olive production profile. While water consumption exceeds harvestable rainwater volumes from May through December, the harvested rainwater is sufficient to meet the firm's needs during the remaining months. Similar to Firm I, the highest water consumption is achieved in October, when the olive fruit collection season begins. Based on these figures, the runoff available from the rooftop of Firm II is also insufficient to meet the annual water demand. However, the harvested rainwater can still supply approximately 70% of the firm's total water requirements.

Figure 3. Water consumption and potential for harvesting rainwater at Firm II

High investment costs and relatively low water prices are often cited as the primary disadvantages of rainwater harvesting (RWH) systems. Our experience indicates that the payback period for these systems decreases as water prices increase. Additionally, if an industry's water consumption aligns with periods of high precipitation, the required storage tank volume can be reduced, thereby improving the investment's feasibility. In addition, the financial arrangements like low-interest loans and other financial support are beneficial for encouraging industries to invest in RWH systems.

The quantity of rainwater that can be collected, as well as its potential uses, are important considerations. This water can be used for various purposes, including landscape irrigation, toilet flushing, cooling water, and process water. Studies have shown that pollutant concentrations in roof runoff are highest at the beginning of a rainfall. The presence of high concentrations of pollutants in the first flush, relative to subsequent runoffs, is termed the 'first flush/first flush' phenomenon. A vortex filter separates suspended particles and pollutants from rainwater, originating from roof dust, through a centrifugal effect, especially during the initial minutes of rainfall, thereby ensuring minimal contamination of the storage tank. Therefore, rainwater harvested from rooftops is suitable for irrigation and toilet reservoirs, in general. However, its use as process water requires special attention to quality. Table olive production processes consist of picking of olives, de-bittering or lye step, rinsing, fermentation in brine, washing, packaging and pasteurization (Dölgen and Alpaslan, 2020). The collected rainwater is a viable option for washing olives and tanks, and rinsing as these tasks don't require high-quality water. For brine preparation, however, the hygienic quality of the stored rainwater is crucial. For this reason, we recommend using filtration and/or disinfection methods to ensure its safety.

Regulatory frameworks play a significant role in encouraging the widespread implementation of rainwater harvesting (RWH) systems. While a 2017 amendment mandated RWH for urban buildings with rooftops of 2000 m² or more, industries are not currently subject to such requirements. To address this, mandatory measures for industrial rainwater harvesting could be explored. Furthermore, offering incentives and benefits to facilities that improve water efficiency through RWH could be a powerful

motivator. Integrating RWH into broader initiatives like "green production" and "green industry" certifications would also enhance its adoption.

CONCLUSIONS

Rainwater harvesting (RWH) systems are substantial infrastructures to promote water efficiency. They offer multiple benefits, including flood mitigation, reduced reliance on municipal water, and lower water costs. While these systems are common in urban settings like homes, shopping centers, and schools, their use in the industrial sector is still limited. However, factories are ideal for RWH due to their large roofs and impermeable surfaces. This makes collected rainwater a promising resource for various industries, including construction, metal, coatings, and agro-industries that process agricultural products. Despite the benefits, high investment costs are a major barrier to adoption. To encourage wider use in the industrial sector, governments could offer financial incentives and integrate RWH into initiatives like "green production" and "green industry" certifications.

ABSTRACT

This study aimed to evaluate the effects of green and red bell pepper (*Capsicum annuum*) powders, in combination with celery (*Apium graveolens*) powder, on the quality characteristics of wheat-based noodles. Two control samples were prepared: one using only refined wheat flour and the other by substituting 10% of the wheat flour with celery powder. In enriched formulations, the celery-containing base was further fortified with 1%, 3%, or 5% green or red bell pepper powder. All samples were analyzed for raw and cooked color attributes (L*, a*, b*, Hue, SI), cooking performance (weight and volume increase, cooking loss), and cooked noodle firmness. The incorporation of red bell pepper powder significantly decreased lightness while increasing redness (a*) and SI, resulting in vivid orange-red noodles. Green bell pepper powder, in contrast, maintained higher lightness and shifted a* values toward the green spectrum, especially at higher substitution levels. Cooking yield increased with the addition of both vegetable powders, while firmness decreased proportionally. Cooking loss remained low in all enriched samples compared to the wheat flour control. Overall, the combined use of celery and bell pepper powders enhanced the nutritional profile and visual appeal of noodles without compromising cooking quality. The results suggest that vegetable powder blends can serve as functional and natural fortification agents in clean-label cereal-based formulations.

Keywords: Vegetable powder, Bell pepper, Celery, Noodles, Functional food, Clean label.

INTRODUCTION

In recent years, the development of functional foods and plant-based fortification strategies has gained significant attention in both academic and industrial fields. Particularly, the incorporation of dried vegetable powders into cereal-based products has emerged as a promising approach to enhance the nutritional value of foods while aligning with consumer demand for health-oriented alternatives (Zhao et al., 2018). Noodles, as a widely accepted traditional cereal product, offer an ideal matrix for such enrichment strategies.

Bell peppers (*Capsicum annuum*), originating from the Mediterranean region, are among the most important vegetables due to their vibrant color, distinctive flavor, and rich nutritional profile. Green and red bell peppers, representing different ripening stages of the same cultivar, are particularly notable for their high content of vitamin C, carotenoids (such as capsanthin and β -carotene), phenolic compounds, and dietary fiber (Marín et al., 2004; Howard et al., 2000). In addition to these common types, several other *Capsicum annuum* cultivars exist, including yellow, orange, purple, and brown

bell peppers, which differ primarily in their pigment composition and antioxidant profiles (Deepa et al., 2007). Among these, green, red, and yellow varieties are the most widely consumed globally.

Bell peppers are commonly utilized in the fresh produce market, canned and frozen vegetable mixes, and dehydrated forms such as powders and flakes. Their application spans multiple sectors including culinary use (e.g., salads, sauces, and stuffed dishes), functional food formulations, and natural colorant sources in the food industry due to their high pigment and antioxidant content (Zhang et al., 2021). When dried and ground into powder form, bell peppers serve as concentrated sources of bioactive compounds and can be incorporated into cereal-based products, snacks, and meat analogues to improve both nutritional quality and sensory appeal (Gonçalves et al., 2016). The inclusion of vegetable powders in noodle formulations may influence various quality parameters, including color characteristics, cooking yield, texture, and solid loss into cooking water. Previous studies have shown that such enrichment can alter both the technological and physicochemical properties of noodles, often resulting in increased water absorption, volume, and improved nutritional density (Wani et al., 2012; Bhasin et al., 2020).

In addition to bell peppers, celery (*Apium graveolens*) is another widely consumed vegetable valued for its distinctive aroma and high nutritional content. Celery is rich in dietary fiber, vitamin K, potassium, and bioactive compounds such as phthalides, flavonoids, and phenolic acids, which contribute to its antioxidant, anti-inflammatory, and hypotensive properties (Sharma et al., 2017; Liu et al., 2018). When processed into powder form, celery retains a substantial portion of its nutrients and phytochemicals, making it suitable for incorporation into cereal-based matrices. Celery powder has been used in food formulations not only as a natural flavoring and coloring agent, but also to improve fiber content and provide functional benefits (Zhou et al., 2020). Its inclusion in noodle formulations may affect the product's color, texture, and cooking quality due to its fibrous and aromatic nature. In composite formulations, the combination of celery powder with other vegetable powders, such as bell peppers, may offer synergistic effects in terms of both sensory characteristics and nutritional enhancement.

In this study, dried green and red bell pepper powders were incorporated into wheat noodle formulations at different levels. The effects of this enrichment were evaluated by analyzing raw and cooked color values (L^* , a^* , b^*), cooked noodle firmness, cooking weight and volume increase, and cooking loss. The findings aim to provide insight into the functional potential of bell pepper powder as a clean-label, natural ingredient for enhancing noodle quality.

MATERIAL AND METHOD

Materials

Fresh green and red bell peppers (*Capsicum annuum*) were purchased from a local market in Konya, Turkey. The raw materials used in noodle production, including refined wheat flour, whole egg, and table salt, were also obtained from a local supplier.

Preparation of Bell Pepper Powders

Green and red bell peppers were washed thoroughly, deseeded, and chopped into thin slices. The slices were initially frozen at $-80\text{ }^{\circ}\text{C}$ for 2 hours and then freeze-dried using a laboratory freeze-dryer (Labconco FreeZone, USA). The dried pepper slices were ground using a laboratory grinder, and the resulting powders were passed through a $500\text{ }\mu\text{m}$ sieve to ensure uniform particle size (Figure 1).

Figure 1. Red and Green bell pepper powders

Noodle Production

In this study, eight different noodle formulations were prepared, including two control samples and six vegetable powder-enriched samples (Table 1). The first control sample (C) was produced using 100% refined wheat flour, while the second control (CC) included 10% celery powder by partially replacing refined wheat flour. For the vegetable-fortified formulations, noodles were prepared by incorporating 10% celery powder and partially substituting the remaining wheat flour with either 1%, 3%, or 5% red bell pepper powder (RC-1, RC-3, RC-5) or green bell pepper powder (GC-1, GC-3, GC-5). In all formulations, the total flour basis (including refined flour, celery powder, and pepper powder) was standardized to 100 g. Each dough was prepared by mixing 100 g of the respective flour blend with 40 g whole egg, 0.5 g salt, and 30 mL distilled water using a planetary mixer (Hobart N50, Offenburg, Germany) at low speed for 8 minutes. The dough was then rested at room temperature for 20 minutes. After resting, the dough was sheeted and cut into noodle strips using a manual pasta machine (Shule Pasta Machine, China). The noodles were then dried at ambient conditions (20–25 °C) for 72 hours before analysis. Representative samples are presented in Figure 2.

Table 1. Formulation codes and descriptions of noodle samples

Sample Code	Formulation Description
C	Control noodle with 100% refined wheat flour
CC	Control noodle with 90% refined wheat flour + 10% celery powder
RC-1	89% refined wheat flour + 10% celery powder + 1% red bell pepper powder
RC-3	87% refined wheat flour + 10% celery powder + 3% red bell pepper powder
RC-5	85% refined wheat flour + 10% celery powder + 5% red bell pepper powder
GC-1	89% refined wheat flour + 10% celery powder + 1% green bell pepper powder
GC-3	87% refined wheat flour + 10% celery powder + 3% green bell pepper powder
GC-5	85% refined wheat flour + 10% celery powder + 5% green bell pepper powder

Color Measurement

Color attributes (L^* , a^* , b^*) of both raw and cooked noodle samples were measured using a colorimeter (Minolta CR-400, Minolta Co., Ltd., Osaka, Japan). Based on a^* and b^* values, hue angle and saturation index (SI) were calculated using the following formulas:

Hue angle = arctangent (b^*/a^*); when $a^* < 0$ and $b^* > 0$, 180° is added to the angle.

Saturation Index (SI) = $\sqrt{a^2 + b^2}$.

Figure 2. Control and bell pepper powder-fortified noodle samples.

Cooking Properties and Firmness

Water uptake, volume increase, and cooking loss were determined following the methods of Oh et al. (1985) and Özkaya and Kahveci (1990). Briefly, for water uptake, 20 g of noodles were cooked in 250 mL of boiling distilled water. The weight of noodles before and after cooking was recorded and expressed as percentage increase. For volume increase, the cooked and drained noodles were placed into graduated cylinders filled with distilled water, and the volume of displaced water was recorded. Cooking loss was determined by drying the filtrate obtained from the cooking water in a drying oven at 135°C until constant weight. Firmness of raw and cooked noodles was evaluated using a texture analyzer (TA-XT Plus, Stable Micro Systems, Surrey, UK), following AACC Standard Method No. 66-50 (AACC, 2000).

Statistical Analysis

Data were statistically analyzed using SPSS version 22.0 (IBM Corp., Armonk, NY, USA). Means were compared using Duncan's multiple range test at a significance level of $p < 0.05$.

RESULTS AND DISCUSSION

Color Properties of Raw Materials

The color characteristics of the raw materials used in noodle formulation, wheat flour, red bell pepper powder, and green bell pepper powder, are shown in Table 2. Color attributes such as lightness

(L*), red-green (a*), yellow-blue (b*), Hue and SI provide important indicators for predicting their visual and functional contribution to final products. Wheat flour showed the highest L* value (94.72), reflecting its bright white appearance. It had a negative a* value (−5.02), and a moderate b* value (13.93). Red bell pepper powder exhibited the lowest L* value (53.59), the highest a* value (38.48), and a high b* value (49.69), indicating its strong red-orange. The Hue (52.25°) and SI (62.85) confirmed the intense, warm coloration dominated by carotenoids such as capsanthin and β -carotene, which are thermally stable and often used as natural colorants in food formulations (Howard et al., 2000; Marin et al., 2004). In contrast, green bell pepper powder showed a relatively high L* value (70.19) and a strongly negative a* value (−12.45), characteristic of green pigments like chlorophyll. Its SI (32.90) was lower than that of red pepper, reflecting its more muted but distinct green tonality. Similar values have been reported in studies evaluating the color profile of green vegetables after drying (Deepa et al., 2007; Zhang et al., 2021). These findings confirm that the choice of vegetable powder significantly impacts the color potential of enriched cereal products. Red bell pepper contributes vibrant, saturated hues, while green bell pepper provides a fresher, vegetal green tone.

Table 2. Color properties of raw materials

<i>Powder type</i>	<i>L*</i>	<i>a*</i>	<i>b*</i>	<i>Hue</i>	<i>SI</i>
Wheat flour	94.72±0.16	-5.02±0.07	13.93±0.10	109.82±0.19	14.81±0.11
Red Bell Pepper	53.59±0.11	38.48±0.13	49.69±0.09	52.25±0.16	62.85±0.09
Green Bell Pepper	70.19±0.09	-12.45±0.13	30.45±0.05	112.24±0.11	32.90±0.10

Color Properties of Uncooked Noodle Samples

The color parameters (L*, a*, b*, Hue and SI) of the uncooked noodles are presented in Table 2. Color is one of the most critical sensory quality attributes affecting consumer perception and preference, and it is significantly influenced by the type and amount of vegetable powder incorporated into the noodle. Incorporation of red bell pepper (RBP) powder significantly ($p < 0.05$) affected all color parameters of uncooked noodles. As the substitution level increased from 0% to 5%, a marked decrease in lightness (L*) was observed (66.49 to 48.46), indicating a darker appearance with higher pigment concentration. Concurrently, redness (a*) values increased sharply from 4.29 to 28.93, reflecting the intense red contributed by carotenoids such as capsanthin and capsorubin, naturally abundant in mature red peppers (Howard et al., 2000). The b* values also increased slightly but remained relatively stable (31.08 to 43.45), enhancing the yellowish-red. Hue angle decreased from 82.14° to 54.95°, confirming the shift from yellow to red tones, while the saturation index (SI) increased significantly (31.38 to 50.38).

Table 3. Color properties of uncooked noodle samples¹

<i>Powder type</i>	<i>Powder ratio (%)</i>	<i>L*</i>	<i>a*</i>	<i>b*</i>	<i>Hue</i>	<i>SI</i>
Red Bell Pepper	0	66.49±0.27a	4.29±0.10d	31.08±0.77b	82.14±0.04a	31.38±0.78c
	1	60.25±0.24b	16.91±0.34c	41.18±1.41a	68.52±0.26b	44.25±1.44b
	3	54.90±1.00c	23.25±0.97b	41.25±1.74a	61.83±0.81c	49.29±1.87a
	5	48.46±0.67d	28.93±0.51a	43.45±0.62a	54.95±0.85d	50.38±0.28a
Green Bell Pepper	0	66.49±0.27a	4.29±0.10a	31.08±0.77b	82.14±0.04d	31.38±0.78b
	1	62.79±0.41b	2.66±0.04b	30.25±0.72b	84.96±0.06c	30.36±0.72b
	3	60.35±0.35c	0.33±0.24c	30.29±0.27b	89.38±0.46b	30.29±0.28b
	5	58.51±1.31d	-0.59±0.10d	33.89±0.79a	90.99±0.16a	33.90±0.79a
<i>Noodle type</i>	<i>N</i>	<i>L*</i>	<i>a*</i>	<i>b*</i>	<i>Hue</i>	<i>SI</i>

Red Bell Pepper	8	57.52±6.97a	18.16±9.62a	39.24±5.12a	66.86±10.50b	43.82±7.96a
Green Bell Pepper	8	62.03±3.18a	1.67±2.01b	31.38±1.66b	86.87±3.67a	31.49±1.63b

¹Means followed by the same letter within a column are not significantly different ($p < 0.05$).

Green bell pepper (GBP) powder also significantly influenced noodle color, but in a contrasting manner. Lightness (L^*) values decreased moderately with increasing GBP levels (66.49 to 58.51), while a^* values gradually shifted from positive to negative (4.29 to -0.59), indicating a transition from slight redness to greenness. This reflects the presence of chlorophyll pigments typical of immature green peppers (Marín et al., 2004). The b^* values remained within a narrow range (30.25–33.89), maintaining a consistent yellow. Hue angle increased significantly from 82.14° to 90.99° , while SI values ranged between 30.29 and 33.90, lower than those observed in red bell pepper-fortified noodles.

The average color values of red and green bell pepper-incorporated noodles are summarized at the bottom of Table 2. Red bell pepper noodles exhibited significantly lower L^* values (57.52) compared to green bell pepper noodles (62.03), indicating darker color. They also showed higher a^* (18.16 vs. 1.67), b^* (39.24 vs. 31.38), and SI values (43.82 vs. 31.49), reflecting more intense red-orange coloration. In contrast, green pepper noodles had a significantly higher hue angle (86.87° vs. 66.86°), characteristic of green–yellow tones.

When compared to the wheat flour control noodle (L^* : 65.63, a^* : 3.19, b^* : 29.29, hue: 83.78° , SI: 29.46), red bell pepper-fortified noodles showed a darker, redder, and more saturated appearance, while green bell pepper noodles were closer in lightness and hue, but still had elevated b^* and SI values. These findings suggest that both types of bell pepper powder significantly altered the visual appearance of the noodles, with red pepper contributing to strong reddish tones, and green pepper offering subtle greenish-yellow hues, consistent with previous reports on color modification in vegetable-enriched pasta and noodles (Zhao et al., 2018; Bhasin et al., 2020).

Color Properties of Cooked Noodle Samples

Cooking significantly alters the color of noodles, particularly due to pigment stability, starch gelatinization, and protein–matrix interactions. The color parameters of cooked noodles enriched with red or green bell pepper powder are presented in Table 4. Incorporation of red bell pepper (RBP) powder significantly ($p < 0.05$) affected all color attributes after cooking. As RBP content increased from 0% to 5%, lightness (L^*) decreased markedly (from 69.61 to 57.15), reflecting the intensification of color due to heat-stable carotenoids like capsanthin. The a^* value, indicating redness, rose from 1.57 to 22.45, while b^* value increased from 22.01 to 45.57, indicating enhanced red-yellow tones. Consequently, hue angle dropped from 85.92° to 63.79° , and saturation index (SI) rose from 22.06 to 50.80, showing more vivid and saturated color as RBP level increased. These findings suggest that red bell pepper pigments are relatively stable under cooking conditions and remain strongly visible in the final product (Howard et al., 2000; Bhasin et al., 2020). Green bell pepper (GBP) powder, in contrast, exhibited a different color behavior after cooking.

The L^* value showed a slight decline at higher concentrations (69.76 to 65.86), indicating minimal darkening. The a^* value, which was positive (reddish) at lower levels, shifted to negative (-1.36 at 5% GBP), signifying a greenish hue attributed to chlorophyll and its derivatives. The b^* values remained around 22–24, and hue angle increased with GBP concentration, reaching 93.20° at 5%, reflecting movement toward the green–yellow quadrant. The SI values ranged from 22.06 to 24.22, much lower than those in RBP noodles, indicating duller but stable coloration. The thermal degradation of chlorophyll to pheophytin during cooking likely contributes to the muted green tone in GBP-fortified noodles (Marín et al., 2004). The control noodle (wheat flour only) exhibited the highest L^* value

(70.42), low redness (a^* : -0.98), and modest b^* (23.37), giving it a pale yellowish appearance. It had a high hue angle (92.42°) and low saturation (SI: 23.39), indicating a relatively bland visual profile.

RBP noodles showed stronger pigmentation, greater redness, and color saturation, confirming the dominance of carotenoid-based pigments. GBP noodles were similar to the control in terms of lightness but displayed a more greenish hue and slightly higher color stability than expected. The differences between RBP and GBP noodles, particularly in a^* and hue values, clearly reflect the distinct pigment profiles of the peppers, carotenoids versus chlorophyll, and their respective thermal stabilities (Zhao et al., 2018).

Cooking Properties of Noodle Samples

Cooking performance is a critical quality parameter for noodles, as it influences consumer acceptance and functional integrity during preparation. The effects of red and green bell pepper powder incorporation on weight increase, volume increase, cooking loss, and cooked firmness are shown in Table 5.

Table 5. Cooking properties of noodle samples¹

<i>Powder type</i>	<i>Powder ratio (%)</i>	<i>Weight increase (%)</i>	<i>Volume increase (%)</i>	<i>Cooking loss (%)</i>	<i>Cooked firmness (g)</i>

¹Means followed by the same letter within a column are not significantly different ($p < 0.05$).

The addition of red bell pepper (RBP) powder significantly influenced the cooking properties of noodles. As the RBP ratio increased from 0% to 5%, weight increase rose from 101.63% to 113.44% ($p < 0.05$), indicating a higher water absorption capacity. Volume increase also increased markedly from 84.44% to 160.71%, suggesting a more porous and expanded noodle matrix. However, cooking loss also increased with higher RBP levels, ranging from 0.50% (control) to 1.17% (5%), possibly due to the leaching of water-soluble pigments and weakly bound solids. Meanwhile, cooked firmness decreased significantly with increasing RBP content (from 1119.03 g to 672.13 g), suggesting a softening effect in the noodle structure. This could be attributed to the dilution of gluten and fiber interference by pepper particles, which has been reported in similar vegetable-enriched pasta formulations (Bhasin et al., 2020). A similar pattern was observed with green bell pepper (GBP) powder. Weight increase rose from 101.63% to 118.23% with 5% GBP incorporation, while volume increase reached 167.86%, showing a stronger swelling tendency than RBP samples. These enhancements may be related to the hydrophilic nature of dietary fiber and carbohydrates in the pepper powder (Marín et al., 2004). Cooking loss also increased from 0.50% to 0.94%, though the rise was more moderate compared to RBP. Interestingly, firmness values decreased significantly as GBP level increased, from 1119.04 g to 629.42 g, which was even lower than the RBP-5 sample. This loss in structural integrity might be due to the weaker colorant-protein interactions and thermal degradation of chlorophyll during cooking (Howard et al., 2000). When averaged across all levels, RBP- and GBP-fortified noodles showed similar trends in cooking performance: both had higher weight gain (~106–107%) and volume expansion (~124%), but lower firmness (~833–887 g) compared to the wheat flour control (firmness: 1196.13 g, weight gain: 94.99%, volume increase: 146.43%).

Notably, the cooking loss of bell pepper-enriched noodles (0.72–0.74%) was substantially lower than the control sample (4.27%), which is likely due to the presence of stabilizing compounds (e.g., fibers, phenolics) that limit starch leaching. This finding is in line with reports suggesting that incorporation of vegetable powders may reduce cooking loss by reinforcing matrix integrity through fiber–starch interactions (Zhao et al., 2018; Bhasin et al., 2020). These results confirm that although firmness decreases with vegetable addition, improvements in water holding, reduced nutrient loss, and visual appeal may compensate for texture softening in functional noodle products.

CONCLUSIONS

The present study demonstrated that the inclusion of red or green bell pepper powder, in combination with celery powder, has a significant influence on the color and cooking quality of wheat-based noodles. Red bell pepper imparted a more intense red-orange hue, while green bell pepper contributed to lighter, greener tones. Both powders improved cooking yield (weight and volume gain) but led to a reduction in firmness due to fiber interference and pigment–protein interactions. Despite the softer texture, cooking loss remained low in vegetable-fortified noodles, highlighting the functional stability of the formulations. Compared to the wheat flour control, the enriched noodles offered superior visual characteristics and enhanced nutritional potential, suggesting their applicability in the development of health-oriented noodle products. These findings support the use of vegetable powders as clean-label ingredients in functional food design, aligning with current consumer preferences for natural, plant-based, and value-added products.

ABSTRACT

This study aimed to evaluate the effects of different oilseeds (sesame, black cumin, blue poppy seed, and flaxseed) and their incorporation at various substitution levels (0%, 3%, 6%, and 9%) on the quality characteristics of crackers. The crackers were evaluated for color, physical, textural, and sensory properties. The addition of oilseed flours significantly affected the product's lightness (L^*), yellowness (b^*), and hue angle depending on the type and level of incorporation. In terms of physical attributes, increasing oilseed content tended to decrease diameter and thickness while increasing spread ratio. Texture analysis showed that hardness values increased with higher substitution levels, particularly at 9%. Sensory evaluation revealed that oilseed enrichment at moderate levels (3–6%) improved taste, crispness, and overall acceptability, while high levels (9%) led to a slight decrease in sensory scores. Among the samples, 6% blue poppy and sesame additions yielded the most favorable sensory and structural outcomes. The results suggest that oilseed-enriched crackers can serve as a valuable source of functional ingredients and improve consumer acceptability without compromising product quality.

Keywords: Snack, Oilseed, Functional food, Bakery product.

INTRODUCTION

The integration of functional foods and health-supporting ingredients into daily diets has become a priority research area in modern nutrition trends (Martirosyan & Singh, 2015). Cereal-based products, in particular, stand out as suitable carrier systems for enrichment with functional ingredients and are among the products with high consumer acceptance (Naqash et al., 2017). In this context, oilseeds, sesame (*Sesamum indicum* L.), black cumin (*Nigella sativa* L.), flaxseed (*Linum usitatissimum* L.), and blue poppy (*Papaver somniferum* L.) are widely used in the development of grain-based products due to their high nutritional value and functional properties.

Sesame seed is particularly notable for its high oil (50–60%), protein (18–25%), dietary fiber, and lignan (sesamin, sesamol) content, and its high antioxidant capacity (Namiki, 2007; Elleuch et al., 2011). Black cumin, with its volatile compounds such as thymoquinone and high phenolic content, exhibits strong antioxidant and antimicrobial properties; its use in functional foods has also been proven (Ali & Blunden, 2003; Ramadan, 2007). Flaxseed, particularly with its α -linolenic acid (ALA), lignans, and soluble, unsaturated dietary fibers, is widely used in functional foods (Kajla et al., 2015). Blue poppy, on the other hand, is preferred in the food industry for its high content of oil (40–50%),

protein (around 20%), and calcium, phosphorus, and iron minerals (Bozan & Temelli, 2008; Siger et al., 2017).

The primary purpose of using oilseeds in bakery products is to enrich their nutritional content (e.g., essential fatty acids, dietary fiber, protein, and phytochemicals) and enhance their functional properties (Altaf et al., 2021; Yilmaz & Toledo, 2005). Furthermore, these seeds enhance both sensory quality and functionality by improving the product's texture, aromatic profile, and shelf life. However, the direct addition of oilseeds to product formulations significantly impacts physical properties such as structure, color, spread, and texture (Metwal et al., 2011; Otondi et al., 2020).

Crackers, being snack products with low moisture content, a crunchy texture, and a long shelf life, are suitable carrier matrices for the addition of functional ingredients. The resulting product is both nutritious and convenient for consumption (Ganorkar & Jain, 2014). In the literature, it is reported that oilseed additive ratios in grain-based snacks generally range from 3–10%, and that these ratios are optimal for achieving a balance between sensory quality and technological suitability (Kaur et al., 2015; Canalis et al., 2019). In products such as crackers, levels of 3–6% provide a significant increase in nutritional value and offer acceptable levels without negatively impacting consumer taste.

In this context, this study aimed to evaluate the sensory, physical, and color properties of products obtained by adding sesame, black cumin, flaxseed, and blue poppy seeds at different ratios (0, 3, 6, and 9%) to cracker formulations. The obtained data will contribute to functional cracker development studies and shed light on the formulation of new, nutritious, and acceptable products that meet consumer demand.

MATERIALS AND METHODS

Materials

Refined wheat flour (type 550), powdered sugar, skimmed milk powder, sodium bicarbonate, shortening, salt, and vanillin were procured from a local retail market in Konya, Turkey. Oilseeds used in the study, sesame (*Sesamum indicum* L.), black cumin (*Nigella sativa* L.), blue poppy seed (*Papaver somniferum* L.), and flaxseed (*Linum usitatissimum* L.), were purchased from a certified organic supplier and ground in a laboratory mill (Retsch ZM200, Germany) to pass through a 500 µm sieve before use.

Preparation of crackers

Cracker doughs were prepared based on a standard low-sugar, low-moisture formulation suitable for crisp bakery products, with varying oilseed incorporation levels of 0%, 3%, 6%, and 9% (w/w) based on flour weight. The control group contained no oilseed powder. All dry ingredients were mixed in a planetary mixer (Hobart-N50; Hobart Canada Inc., Ontario, Canada) for 5 minutes, followed by the addition of water to obtain a firm but pliable dough. The dough was sheeted to a thickness of approximately 3 mm, cut into circular discs of 45 mm diameter, and baked in a laboratory oven (Profilo

HG1503T, İstanbul, Turkey) at 170 °C for 14 minutes. After cooling to 25 ± 2 °C, crackers were sealed in polyethylene bags and stored at room temperature until analysis.

Color analysis

The surface color of the cracker samples was measured using a Minolta CR-400 colorimeter (Minolta Camera Co., Ltd., Osaka, Japan). Results were recorded as L^* (lightness), a^* (red-green axis), and b^* (yellow-blue axis) values. In addition, Saturation index ($((a^{*2} + b^{*2})^{1/2})$) and Hue angle ($a^* > 0$ and $b^* > 0$, if $\arctan [b^*/a^*]$; $a^* < 0$ and $b^* > 0$, $\arctan [b^*/a^*] + 180^\circ$) values were calculated (Francis, 1998).

Physical properties

The diameter and thickness of the crackers were measured with a digital caliper (Mitutoyo, Japan, precision 0.01 mm) at five different points per sample, and the spread ratio was calculated as the ratio of diameter to thickness (AACC, 2000).

Texture profile analysis

The hardness of the crackers was measured 2 hours after baking using a Texture Analyzer (TA-XT2i; Stable Microsystems, UK) equipped with a three-point bending rig (HDP/3PB). Test conditions were: load cell: 30 kg, pre-test speed: 1.0 mm/s, test speed: 3.0 mm/s, post-test speed: 10.0 mm/s, test distance: 5 mm, and trigger force: 50 g. The maximum force recorded at break was reported as the hardness value (g).

Sensory evaluation

Sensory analysis was conducted with a panel of 20 untrained participants from Necmettin Erbakan University (Konya, Turkey) who regularly consume bakery products. Each panelist evaluated the cracker samples for color appearance, odor, taste, crispness, and overall acceptability using a 7-point hedonic scale (1 = dislike extremely, 7 = like extremely). Each panelist evaluated the coded samples in random order under daylight and ambient conditions.

Statistical analysis

All measurements were carried out in duplicate. The obtained data were analyzed using JMP statistical software version 10.0 (SAS Institute Inc., Cary, NC, USA). Analysis of variance (ANOVA) was performed to determine significant differences ($p < 0.05$) among the means, and comparisons were made using Tukey's HSD post-hoc test.

RESULTS AND DISCUSSION

Color Properties of Raw Materials

The visual quality of cracker products is strongly influenced by the color characteristics of the raw materials used in their formulation. Table 1 provides the L^* , a^* , b^* , Hue, and Saturation Index (SI) values for the base flour and seed powders utilized in this study. The results indicated that all color parameters varied significantly depending on the material type ($p < 0.05$). Refined wheat flour exhibited the highest L^* value (91.64), demonstrating its brightness and whiteness, attributes typically associated with traditional noodle products. Conversely, black cumin (33.85) and blue poppy (33.45) powders had the lowest L^* values, reflecting their darker pigmentation, which can be attributed to their rich content of phenolic compounds and natural pigments (Sarikurkcu et al., 2015). Flaxseed and sesame powders displayed intermediate L^* values (53.50 and 71.81, respectively), indicating moderate brightness levels.

In terms of the a^* coordinate (red-green axis), values ranged from -0.36 in wheat flour to 6.08 in flaxseed powder. The elevated a^* value in flaxseed suggests a dominant reddish-brown hue, likely related to the presence of lignans and tannins (Hu et al., 2007). Blue poppy showed a moderate a^* value (3.24), while sesame and black cumin had relatively low values (0.69 and 0.82), suggesting less chromatic deviation toward red or green. Regarding b^* values, which indicate yellowness, sesame powder had the highest value (19.52), followed by flaxseed (16.97), both of which contribute yellow-brown hues to the end product. Wheat flour had a lower b^* value (12.50) despite its high lightness, whereas black cumin and blue poppy exhibited minimal b^* values (2.78 and 3.31), aligning with their cool and subdued visual appearance.

The Hue angle, indicating the dominant shade of color, ranged from 45.54 in blue poppy to 91.63 in wheat flour. A lower hue angle in blue poppy reflects a tendency toward bluish-red tones, while higher values in wheat flour and sesame are indicative of neutral to yellowish hues (Pathare et al., 2013). The Saturation Index, which quantifies color intensity, was highest in sesame (19.54) and flaxseed (18.03), suggesting more vivid coloration, while black cumin had the lowest SI (2.90), reinforcing its dull and dark character. These findings highlight the distinct color attributes of seed powders, implying that their incorporation into noodle formulations is likely to produce noticeable changes in the visual attributes of the final product. This observation is consistent with previous literature indicating that the addition of naturally pigmented functional ingredients can significantly alter the visual appeal and consumer acceptance of cereal-based foods (Kähkönen et al., 1999; Pathare et al., 2013).

Table 1. Color properties of raw materials

Raw material type	L^*	a^*	b^*	Hue	SI
Wheat flour	91.64±0.03a	-0.36±0.01d	12.50±0.08c	91.63±0.02a	12.50±0.08c
Sesame	71.81±0.48b	0.69±0.10c	19.52±0.23a	87.98±0.31b	19.54±0.23a
Black cumin	33.85±0.78d	0.82±0.13c	2.78±0.18e	73.67±1.64c	2.90±0.21b

Color properties of crackers

Color is one of the most important quality indicators that directly affects consumer acceptability of bakery products (Pathare et al., 2013). The instrumental color values (L^* , a^* , b^* , Hue angle, and SI) of the cracker samples produced with different seed types and varying additive levels are presented in Table 2. Among the different seed types, significant variations ($p < 0.05$) were observed in all color parameters of the cracker samples. Sesame-added crackers exhibited the highest L^* value (77.71), indicating a lighter appearance, whereas black cumin crackers had the lowest lightness ($L^* = 63.85$), resulting in a darker product surface. This variation may be attributed to the intrinsic pigment composition and thermal behavior of the seed materials during baking (Gandhi et al., 2022; Pawase et al., 2020). In terms of a^* values, blue poppy and flaxseed crackers showed the highest redness values (1.25 and 1.15, respectively), while sesame (0.48) and black cumin (0.75) crackers exhibited significantly lower redness values. The observed differences in red/green color tones could be due to the seed skin pigments, including anthocyanins or other polyphenolic compounds, which may undergo complex Maillard and caramelization reactions during baking (Wang et al., 2022). Regarding b^* values, which indicate yellowness, sesame crackers had the highest value (29.21), followed by flaxseed (24.82) and blue poppy (22.66), whereas black cumin crackers had the lowest (19.07). These findings suggest that sesame and flaxseed contribute more prominently to yellowish hues, potentially due to their higher oil content and carotenoid levels (Radwan et al., 2017). Hue angle and Saturation Index (SI) values were generally consistent with the L^* , a^* , and b^* trends, with sesame crackers showing the most saturated and yellow-toned color appearance (Hue: 89.41, SI: 29.23), and black cumin resulting in a duller and less saturated appearance (SI: 19.08). When evaluating the impact of increasing additive ratios (0–9%), a general decreasing trend in lightness (L^*) was observed. The control crackers (0%) had an L^* value of 72.86, which slightly increased at 3% (74.57), likely due to dilution of browning reactants at low substitution levels. However, further increases in additive content to 6% and 9% significantly reduced lightness values (68.99 and 67.55, respectively), possibly due to intensified Maillard reactions and pigment accumulation from the seed additives (Otondi et al., 2020). Redness (a^*) values showed a distinct fluctuation with increasing substitution levels.

Table 2. Color values of crackers

¹Means with the same letter within a column are not significantly different ($p > 0.05$). Hue: Hue angle, SI: Saturation index.

The highest a^* value was observed in the control (2.22), which significantly decreased at 3% substitution (-0.21), indicating a shift toward green tones. However, a^* values increased again at 6%

and 9% (0.49 and 1.11, respectively), suggesting potential pigment release or interaction effects at higher levels of incorporation (Singh & Gaur, 2024). The b^* values and SI followed a similar trend, decreasing significantly as the additive ratio increased from 0% to 9%, with the highest yellowness and color saturation found in the control (b^* : 37.79, SI: 37.85) and the lowest in the 6% and 9% substituted samples. Hue angle values ranged between 86.38 and 90.55, with the 3% addition yielding the highest hue angle, implying a slight shift toward a greener/yellower hue. These observations indicate that both the seed type and additive ratio significantly affect the visual appearance of crackers, which may influence consumer perception and marketability. Therefore, optimizing seed type and its level of incorporation is essential to balance functional enrichment with acceptable color characteristics.

Physical properties of crackers

The physical characteristics of crackers, such as diameter, thickness, spread ratio, and hardness, provide critical insights into dough behavior during baking and the final product's textural and visual qualities. Table 3 presents the measured physical parameters of crackers enriched with different types and ratios of oilseeds. Significant variations ($p < 0.05$) were observed among seed types in terms of diameter, thickness, spread ratio, and hardness. Crackers containing blue poppy exhibited the largest diameter (45.44 mm), while black cumin samples had the smallest (44.47 mm). However, all samples were within a narrow range, indicating a limited influence of seed type on diameter. In terms of thickness, most crackers showed similar values (around 7 mm), except for the black cumin sample, which had a significantly lower thickness (6.42 mm). Consequently, the spread ratio (diameter/thickness) was highest in black cumin crackers (7.02), suggesting greater lateral expansion during baking. This may be attributed to the oil content and particle size of black cumin, which could reduce dough viscosity and increase spread ability (Mamat & Hill, 2014).

Hardness, representing the force required to break the sample, varied significantly with seed type. The hardest sample was observed in black cumin (1115.75 g), followed by sesame (1076.58 g), while the blue poppy sample was the softest (976.03 g). These differences are likely due to the fat and fiber composition of each seed type, which influences water absorption and dough matrix development during baking (Otondi et al., 2020; Metwal et al., 2011). Higher oil absorption in black cumin may have led to reduced moisture retention, producing a firmer texture.

Cracker samples prepared with increasing additive levels (0–9%) also showed distinct changes in physical properties. The control sample (0%) exhibited the largest diameter (46.30 mm) and thickness (7.59 mm), resulting in the lowest spread ratio (6.13). This suggests that the incorporation of seed powders disrupts the dough matrix and affects its baking behavior, possibly by altering gluten network strength or water distribution (Gupta et al., 2014). As the additive ratio increased, both diameter and thickness decreased significantly ($p < 0.05$). At 3–9% levels, diameter values remained around 44.4–44.8 mm, while thickness dropped to ~6.7 mm, resulting in higher spread ratios (6.66–6.75). This increase in spread ratio with additive incorporation may be attributed to reduced dough cohesion and increased fat migration from the seeds during baking (Altaf et al., 2021).

The most prominent difference was observed in hardness values. The control sample was the softest (864.34 g), while the 9% substituted crackers were the hardest (1304.76 g). The progressive increase in hardness with higher seed addition may be due to higher dietary fiber and protein content, which can reinforce the dough structure, reduce expansion, and limit moisture retention, thereby yielding a firmer texture (Metwal et al., 2011; Naqash et al., 2017). These results collectively indicate that both the type and concentration of oilseed additives significantly influence the physical attributes of crackers, particularly hardness and spread ratio, key determinants of consumer texture perception.

Table 3. Physical properties of crackers

<i>Cracker type</i>	Diameter (mm)	Thickness (mm)	Spread ratio (W/T)	Hardness (g)
Sesame	45.05±1.13a	7.06±0.74a	6.44±0.66b	1076.58±192.75ab
Black cumin	44.47±1.47b	6.42±0.85b	7.02±0.77a	1115.75±220.77a
Blue poppy	45.44±0.87a	7.19±0.65a	6.37±0.56b	976.03±133.34c
Flaxseed	45.10±1.22a	7.05±0.51a	6.42±0.44b	1035.75±171.06b
Additive ratio (%)

¹Means with the same letter within a column are not significantly different ($p > 0.05$).

Sensory Evaluation of Cracker Samples

The sensory evaluation of crackers formulated with different oilseed types—namely sesame, black cumin, poppy, and flaxseed—was conducted using a 7-point hedonic scale to assess attributes including color, appearance, odor, taste, crispness, and overall acceptability (Table 4, Figure 2). The enrichment with oilseeds significantly influenced the sensory characteristics of the final products, in line with previous studies indicating that the type and concentration of added functional ingredients can modify consumer perception and preference (Desai et al., 2010; Gçetek et al., 2020).

Crackers enriched with sesame exhibited improved taste, crispness, and overall acceptability, particularly at substitution levels of 3% and 6%. However, a decline in these attributes was noted at the 9% level, suggesting a sensory saturation threshold beyond which product quality may be adversely affected. The positive impact of sesame at moderate levels may be attributed to its pleasant nutty flavor and natural oil content, which contribute to desirable textural and aromatic properties (Yilmaz and Doga, 2012).

In black cumin-supplemented crackers, the highest scores for odor and crispness were recorded at the 6% inclusion level. Nevertheless, sensory acceptance decreased at the 9% substitution rate, particularly for taste and overall liking. This could be associated with the intense and pungent aroma of black cumin, driven by its volatile compounds such as thymoquinone and carvacrol, which at higher concentrations may overwhelm the sensory balance of baked products (Amin and Husain, 2021; Singh et al., 2018).

Poppy seed-enriched crackers demonstrated consistent and balanced sensory profiles across all substitution levels. Notably, the 6% inclusion level yielded the highest scores across all parameters evaluated, indicating an optimal level that enhances sensory perception without compromising palatability. Poppy seeds are known for their mild nutty flavor and appealing texture, making them suitable for incorporation into cereal-based snacks (Koç et al., 2015).

For flaxseed-containing crackers, the 3% and 6% incorporation levels were generally well-received, enhancing taste and crispness. However, at the 9% level, a slight decline in sensory scores was observed in some attributes, potentially due to the mucilaginous nature of flaxseed components or the earthy flavor profile becoming more pronounced (Kajla et al., 2015). The partial decline in liking at higher doses is consistent with reports indicating that flaxseed's sensory contribution is dose-dependent and may influence consumer acceptability when used in excess (Wiesenborn et al., 2000).

Table 4. Sensory evaluation scores of crackers enriched with different oilseeds and substitution levels

<i>Oilseed type</i>	<i>Color/Appearance</i>	<i>Odor</i>	<i>Taste</i>	<i>Crispness</i>	<i>Overall Acceptability</i>
Sesame	5.88±0.23b	5.68±0.24ab	5.83±0.11a	5.80±0.12a	5.83±0.13ab
Black cumin	5.75±0.10c	5.63±0.31bc	5.58±0.25b	5.65±0.15b	5.65±0.09c
Blue poppy	5.98±0.09a	5.71±0.12a	5.83±0.08a	5.83±0.23a	5.88±0.11a
Flaxseed	5.88±0.13b	5.58±0.09c	5.73±0.12a	5.88±0.06a	5.78±0.06b
<i>Additive ratio (%)</i>					
0	5.50±0.08d	5.20±0.09d	5.40±0.11c	5.60±0.06b	5.50±0.06d
3	5.83±0.03c	5.80±0.03b	5.93±0.00a	6.03±0.17a	5.96±0.11b
6	6.00±0.09b	5.98±0.00a	6.00±0.09a	6.95±0.21a	6.05±0.06a

9	6.15±0.11a	5.60±0.11c	5.63±0.24b	5.58±0.13b	6.65±0.05c

¹Means with the same letter within a column are not significantly different ($p > 0.05$).

Overall, the results underscore that low to moderate substitution levels of oilseeds (particularly in the 3–6% range) are effective in enhancing the sensory quality of crackers without inducing undesirable sensory effects. Excessive enrichment may lead to overpowering flavors or textural imbalances that diminish consumer satisfaction. These findings are in agreement with prior research suggesting that optimal incorporation levels of functional ingredients are critical in balancing health benefits and sensory acceptance in bakery products (Metwal et al., 2011; Nawaz et al., 2021).

CONCLUSIONS

The enrichment of crackers with functional oilseeds such as sesame, black cumin, blue poppy, and flaxseed has shown potential for enhancing nutritional and sensory quality. Moderate incorporation levels (3–6%) improved texture and taste while maintaining structural integrity and visual appeal. However, higher substitution levels (9%) negatively affected hardness and sensory attributes. Overall, the study indicates that oilseed incorporation at optimal levels can contribute to the development of health-promoting bakery products with enhanced consumer acceptance. These findings provide a scientific basis for the formulation of functional crackers with targeted health benefits and desirable quality characteristics.

ABSTRACT

This study quantifies the greenhouse gas emissions of agricultural activities in Aliaga (İzmir, Türkiye) using a cradle-to-gate Life Cycle Assessment and evaluates the mitigation potential of onshore wind energy via scenario analysis. Under Tier 1 methods of the 2006 IPCC Guidelines for agricultural soils, the district's total footprint was estimated at 6,410.38 t CO₂e, with 81.9% arising from fertilizer-driven N₂O (direct and indirect) and 18.1% from fuel use; the area-normalized intensity is 0.56 t CO₂e/ha, consistent with regional/global ranges. The Çandarlı-Yeni şakran sites produce 6-7 m/s wind speeds, enabling four wind-integration scenarios sized 1-5 MW. The most ambitious case (5 MW, mixed irrigation and mechanization, 1.75 GWh/y allocated to farm loads) yields 1,206 t CO₂e/y abatement (16.5% of the baseline) under diesel displacement (0.7-0.9 kg CO₂/kWh); the same allocation under grid displacement (0.4-0.5 kg CO₂/kWh) delivers 790 t CO₂e/y. Combined measures-N management (dose/timing, nitrification inhibitors, organic inputs) and on-farm wind power-can plausibly achieve 20% total reduction.

Keywords: Life Cycle Assessment; agricultural GHGs; nitrous oxide; wind energy; irrigation

INTRODUCTION

Climate change has made the reduction of greenhouse gas (GHG) emissions an urgent global priority. According to IPCC (2006), agricultural activities account for approximately 10-12% of global GHG emissions, primarily driven by nitrous oxide (N₂O) emissions from fertilizer use, carbon dioxide (CO₂) emissions from fuel combustion, and indirect emissions associated with irrigation.

In Türkiye, the agricultural sector contributes 13.4% of the country's total GHG emissions (TÜİK, 2025). Greenhouse gases sources include fertilizer application, mechanization, and energy-intensive irrigation systems. Electric energy use has been reported at 450-700 kWh per hectare for crop production and processes for crop production produced about 20% of total greenhouse emissions (Özkan et al., 2004). For cereal production in Türkiye, fertilizer-driven N₂O emissions may reach 100-120 kg CO₂e per hectare, while in the Aegean Region this level can be higher due to clay-loam soils (Çetin & Vardar, 2019). In agricultural areas similar to Aliaga, clay-loam soils with 1.5-2.5% organic matter tend to have higher nitrogen retention, which encourages fertilizer use and further elevates emissions (Kiper, 2018). Mitigation practices such as precision fertilization, drip irrigation, and organic amendments are suggested to reduce emissions by 20-30% (FAO, 2020). Reducing these greenhouse emissions is essential for Türkiye to meet its Paris Agreement commitments and 2053 Net Zero target.

Life Cycle Assessment (LCA) is a standard method for quantifying the carbon footprint of agricultural systems. The international literature indicates that LCA can effectively inform agricultural mitigation strategies; for example, FAO (2020) reports 15-25% emission reductions through LCA-based optimization.

Wind energy emerges as a renewable and sustainable option for reducing agricultural emissions. Globally, wind accounts for roughly 7% of electricity generation, and its use in energy-intensive on-farm operations can reduce fossil fuel consumption by 30-50% (IEA, 2023). Horizontal-axis wind turbines offer high conversion efficiency; a 1 MW turbine can generate around 3,000 MWh annually, yielding an estimated 1,350 t CO₂e reduction (IRENA, 2023). Integrating turbines into agricultural landscapes can maintain production while supplying energy, as turbine footprints typically occupy only 1-2% of land without compromising yields (IEA, 2023).

According to the Ministry of Energy and Natural Resources (2023), national installed wind capacity exceeds 12 GW, with the Aegean Region contributing about 25% of this capacity. İzmir offers attractive wind regimes of 6-8 m/s. In Aliğa, annual average wind speeds of 6-7 m/s indicate strong siting potential (MGM, 2025). In İzmir, applying wind-powered systems to irrigation can reduce energy consumption by 40% and emissions by 15-20% (Kiper, 2018). For example, powering vegetable irrigation pumps in Aliğa with wind energy could lower indirect CO₂ emissions by up to 20%.

In the Netherlands, farm-integrated turbines have supplied energy for irrigation pumps and greenhouse heating, cutting emissions by 25-30% (IRENA, 2023). In Germany's Baden-Württemberg, small turbines used for farm mechanization and electric equipment reduced emissions by 15-20% (IEA, 2023). In Türkiye, the Çeşme wind power plant (WPP) operates near agricultural zones in İzmir, providing power that indirectly supports nearby agricultural processes (Ministry of Energy and Natural Resources, 2023).

Aliğa is a strategic district where agriculture and industry. Aliğa, located in İzmir Province, is a major agricultural hub with 11,370 hectares of farmland producing cereals, fruits, and vegetables. However, industrial activities have led to land loss, soil degradation, and air pollution, necessitating innovative solutions to reduce agricultural emissions.

Aliğa's wind resource strengthens its suitability for agricultural decarbonization. In the district's northwestern sections (Çandarlı, Yenişakran), 6-8 m/s winds are common, offering multiple turbine siting options (MGM, 2025). Kiper (2018) suggests piloting wind integration into irrigation and mechanization in Aliğa. For instance, a 1 MW turbine in Çandarlı could fulfill the irrigation energy demand of approximately 500 ha of vegetable cultivation (350,000 kWh/year) and deliver 157.5 t CO₂e annual emission reductions (IRENA, 2023). However, Çetin & Vardar (2019) and Kiper (2018) analyze agricultural emissions in İzmir, they do not focus on mitigation through wind energy. International literature (IEA, 2023; IRENA, 2023) highlights wind's potential in agricultural decarbonization, but specific applications are still limited in Türkiye.

This study analyzes the carbon footprint of agricultural activities in Aliğa using Life Cycle Assessment (LCA) and evaluates the environmental impacts of agricultural processes in Aliğa by modeling emissions from fertilizers (N₂O), on-farm fuel use (CO₂), and irrigation (indirect CO₂). Pesticide-related and waste-related emissions are excluded due to data gaps. In addition, this study evaluates the potential of wind turbines to mitigate emissions after determination of greenhouse emissions.

MATERIAL AND METHOD

The study (i) quantifies the cradle-to-gate greenhouse gas (GHG) footprint of Aliğa's agricultural production and (ii) evaluates wind-to-farm electrification scenarios for irrigation and mechanization.

The İzmir Provincial Directorate of Agriculture and Forestry (2025) reports that the study area (Aliğa Region) has 11,370 ha of agricultural land distributed as cereals (40%, 4,548 ha), fruits (35%, 3,979.5 ha), vegetables (20%, 2,274 ha), and other crops (5%, 568.5 ha). Wheat (10,291 t) and olive (6,689 t) dominate local agricultural output (BEPA, 2025). Soil is clay-loam with 1.5-2.5% organic matter. The Mediterranean climate features 17°C average temperature, 600 mm rainfall, and 65% humidity.

Life Cycle Assessment (LCA) follows ISO 14040 (2006) using cradle-to-gate approach. Two functional units are used: 1 ha-year and (where available) per-ton of product. System boundaries include upstream supply and on-farm application stages; post-harvest transport/processing are excluded.

Datas for assumptions and calculations;

Primary datas;

Crop Production: The 2024 production data for Aliğa were obtained from BEPA (2025) and the İzmir Provincial Directorate of Agriculture and Forestry are given Table 1. Sample datas: wheat (10,291 tons, 4,000 ha), olive (6,689 tons, 3,500 ha), tomato (4,500 tons, 1,000 ha).

Irrigation and Mechanization: Data on irrigation systems (60% drip, 30% sprinkler, 10% surface) and mechanization (tractors, harvesting machines) were collected from the Aliğa Chamber of Agriculture.

Secondary datas;

Fertilizer for crops;

Fertilizer use for production of crops and generally range of fertilizer dose is approximately 100-150 kg/ha according to crops such as creals 100 kg/ha, vegetables 150 kg/ha, fruit 80 kg/ha. Fertilizer generally includes 50% nitrogen-based fertilizer (ürea), 30% phosphorus-based fertilizer (P_2O_5) and %20 potassium-based fertilizer (K_2O). (TÜİK, 2025; Çetin and Vardar, 2019; Kiper, 2018).

CO₂e emissions factors for production of fertilizer;

3,5 kg CO₂e /kg N; 0,7 kg CO₂e /kg P_2O_5 ; 0,5 kg CO₂e /kg K_2O ;

Direct and indirect N₂O emissions;

Calculation of direct and indirect N₂O emissions;

$$N_2O-N_{direct}=N_{applied} \times EF1;$$

$$N_2O_{direct}=N_2O-N_{direct} \times 44/28;$$

$$CO_2e=N_2O_{direct} \times GWP_{N_2O}$$

Direct N₂O emissions are calculated using the EF factor; EF1 = 0.01 kg N₂O-N per kg of applied N.

Indirect N₂O emissions from volatilization and leaching follow IPCC Tier guidelines. N₂O emissions are converted to CO₂e using the Global Warming Potential (GWP) for N₂O: AR5=265 kg CO₂e per kg N₂O.

CO₂e production from Fuel use;

Calculation of CO₂e emissions;

kg CO₂e (for fuel usage) = Cultivated area (ha) × diesel consumption for product (L/ha) × diesel EF CO₂e/L

Fuel used for mechanization such as truck etc. at 30 L/ha (cereals), 50 L/ha (vegetables), 40 L/ha (fruit), diesel EF=2.68 kg CO₂/L (Özkan etc., 2004; Çanakçı etc., 2010).

Irrigation Energy;

Irrigation energy includes electric and diesel pumps used for crop irrigation. Typically, electric pumps consume 450-700 kWh per hectare per year, while diesel pumps consume 10-15 liters per hectare per year (FAO, 2020; İzmir Provincial Directorate of Agriculture and Forestry, 2025).

For electric pumps;

CO₂e= kWh×EF_{grid}

Grid electricity EF (Türkiye); 0,45 kg CO₂/kWh

For diesel pumps;

CO₂e=L_{diesel}× Diesel EF

Diesel EF=2.68 kg CO₂/L

Wind capacity;

The Aliğa district lies in a high-wind coastal belt of the North Aegean; Global Wind Atlas and MGM (Turkish State Meteorological Service) indicate 6-8 m/s velocity with power densities of 400-500 W/m².

RESULTS AND DISCUSSION

The İzmir Provincial Directorate of Agriculture and Forestry (2025) reports that the study area (Aliğa Region) has 11,370 ha of agricultural land distributed as cereals (40%, 4,548 ha), fruits (35%, 3,979.5 ha), vegetables (20%, 2,274 ha), and other crops (5%, 568.5 ha). Total greenhouse emissions according to crops in Aliğa Region are given Table 1.

In Aliğa, total emissions amount to 6,410.38 t CO₂e, with 81.9% (5,250.60 t CO₂e) originating from fertilizers and 18.1% (1,159.78 t CO₂e) from fuel use. Fertilizer emissions include N₂O from soil and production of nitrogen, phosphorus and potassium-based fertilizers. Nitrogen based fertilizer emissions include both direct and indirect N₂O. Aliğa's emissions per hectare (0.56 tons CO₂e/ha)

are consistent with those of the Aegean Region (0.5-1.2 tons CO₂e/ha) and global averages (0.6-0.9 tons CO₂e/ha). The intensity is 0.56 t CO₂e/ha, a range consistent with regional and global agricultural intensities for similar systems.

Table 1. Total greenhouse emissions according to crops in Aliğa Region

Product	Production (tons)	Cultivated Area (ha)	Fertilizer Emissions (tons CO ₂ e)	Fuel Emissions (tons CO ₂ e)	Total Emissions (tons CO ₂ e)
Barley	5,376	1,792	666.23	96.05	762.28

In terms of product group contributions, cereals lead with 43.8%, followed by fruits at 21.3%, vegetables at 5.5%, and others at 29.5%; this distribution reflects both land use shares and nitrogen input profiles. According to calculations, wheat (1,458.52 tons CO₂e), olive (1,137.36 tons CO₂e), and silage maize (1,179.54 tons CO₂e) show highest greenhouse emissions due to large cultivation areas and fertilizer use. Tomatoes (147.15 tons CO₂e) and watermelons (46.69 tons CO₂e) also have high emissions due to intensive inputs. Oleaster (0.43 tons CO₂e) and apple (1.02 tons CO₂e) have the lowest emissions with minimal cultivation areas.

A significant majority 81.9% of total greenhouse gas emissions, amounting to 5,250.60 tons of CO₂ equivalent (tons CO₂e), stem from fertilizer use. In contrast, fuel combustion accounts for the remaining 18.1%, corresponding to 1,159.78 tons CO₂e. Emissions related to fertilizers include both upstream processes, such as the industrial production of nitrogen-based fertilizers, and downstream impacts like nitrous oxide (N₂O) emissions released from soils. Additionally, phosphorus and potassium fertilizers contribute to the total emissions, with estimated emission factors of 0.7 kg CO₂e per kilogram of phosphorus and 0.5 kg CO₂e per kilogram of potassium applied. Emission source and CO₂ gas emissions are given Table 2.

Table 2. Emission source and CO₂ gas emissions (ton CO₂e)

Emission Source	Emissions (tons CO ₂ e)	Percentage (%)
Nitrogen Fertilizer	4,202.98	65.6
Phosphorus Fertilizer	707.00	11.0
Potassium Fertilizer	340.62	5.3
Fuel (Diesel)	1,159.78	18.1

Aliağa's wind resource strengthens its suitability for agricultural decarbonization. In the district's northwestern sections (Çandarlı, Yenişakran), 6-8 m/s winds are common, offering multiple turbine siting options. Wind energy integration into irrigation and mechanization in Aliağa is possible and effective way to decrease emissions in agricultural area. In the emission reduction calculations, only the portion of wind energy allocated specifically to farm operations was considered. For estimating the impact of diesel displacement, a practical emissions factor ranging from 0.7 to 0.9 kg CO₂ per kilowatt-hour (kWh) was used. This range is based on the specific fuel consumption of diesel engines and the carbon content of diesel fuel. In the case of grid electricity displacement, an emissions

factor of 0.4 to 0.5 kg CO₂/kWh was applied, in line with recent data from the International Energy Agency (IEA) for Türkiye.

The Aliğa district benefits from consistent wind speeds ranging between 6 and 7 meters per second, which are ideal for the operation of modern onshore wind turbines. This renewable energy potential presents a compelling opportunity to substitute conventional energy sources used in agriculture, particularly for irrigation systems and mechanized farm operations. Wind turbines installed in Çandarlı, where wind speeds reach 7 m/s, and in Yenişakran, with 6 m/s, have the capacity to reduce agricultural greenhouse gas emissions by 1.1% to 16.5%, depending on the scale and application. This study evaluates four wind energy deployment scenarios based on their capacity and corresponding emission reduction potential. Scenario results are given Table 3 according to replacement and decrease of emissions.

Table 3. Wind scenarios and annual abatement (ton CO₂e/y)

Scenario	Site/Capacity	Electricity allocated (kWh/y)	Diesel displacement (0.8 kg/kWh)	Grid displacement (0.45 kg/kWh)
S1	Çandarlı/1 MW	350,000	280	158
S2	Çandarlı/3 MW	1.170,000-1.300,000	938	525-585
S3	Yenişakran/2 MW	190 000-350 000	150-280	158
S4	Çandarlı+Yenişakran/5MW	1,750,000	1,400	788

According to Table 3, a 1 MW wind turbine installation at Çandarlı allocates 350,000 kWh of electricity annually, resulting in a reduction of 280 tons of CO₂e through diesel displacement and 158 tons of CO₂e via grid electricity substitution in Scenario S1. At scenario S2, with a larger 3 MW capacity at the same site, provides between 1.17 and 1.30 million kWh per year, leading to a substantial reduction of 938 tons CO₂e from diesel and 525-585 tons CO₂e from grid displacement. Scenario S3, located in Yenişakran with a 2 MW capacity, allocates between 190,000 and 350,000 kWh annually, achieving 150-280 tons CO₂e reduction from diesel and 158 tons CO₂e from grid electricity. Finally, Scenario S4 combines both sites with a total capacity of 5 MW, delivering 1.75 million kWh per year and yielding the highest overall emission reductions: 1,400 tons CO₂e from diesel and 788 tons CO₂e from grid displacement. These findings underscore the critical role of wind energy in mitigating greenhouse gas emissions, particularly when replacing high-carbon sources such as diesel fuel. For instance, a 5 MW wind turbine could achieve an annual emission reduction of approximately 1,400 tons of CO₂ equivalent, representing the upper bound of this mitigation potential.

CONCLUSIONS

In Aliğa, total greenhouse emissions amount to 6,410.38 t CO₂e, with 81.9% (5,250.60 t CO₂e) originating from fertilizers and 18.1% (1,159.78 t CO₂e) from fuel use. Fertilizer emissions include N₂O from soil and production of nitrogen, phosphorus and potassium-based fertilizers. Nitrogen based fertilizer emissions include both direct and indirect N₂O. Aliğa's emissions per hectare (0.56 tons CO₂e/ha) are consistent with those of the Aegean Region (0.5-1.2 tons CO₂e/ha) and global averages (0.6-0.9 tons CO₂e/ha). The intensity is 0.56 t CO₂e/ha, a range consistent with regional and global agricultural intensities for similar systems.

The Aliğa district benefits from consistent wind velocity ranging between 6 and 7 meters per second, which are ideal for the operation of modern onshore wind turbines. This renewable energy potential presents a compelling opportunity to substitute conventional energy sources used in

agriculture, particularly for irrigation systems and mechanized farm operations. Wind turbines planned to install in Çandarlı, where wind speeds reach 7 m/s, and in Yenişakran, with 6 m/s, have the capacity to reduce agricultural greenhouse gas emissions by 1.1% to 16.5%, depending on the scale and application. Wind energy's role in emission reduction was analyzed through four different scenarios. The most effective scenario, involving a 5 MW wind turbine, achieved a reduction of 1,400 tons CO₂e (16.5%) through combined use in irrigation and mechanization, demonstrating the effectiveness of renewable energy in mitigating agricultural emissions.

To further reduce the carbon footprint of agriculture in Aliğa, the study recommends several strategies: optimizing nitrogen fertilizer use, integrating wind energy, adopting organic fertilizers, shifting to low-emission crop varieties such as oleaster and apple, validating field-level data, and implementing farmer education programs. Through the adoption of precision farming techniques and renewable energy systems, Aliğa holds strong potential to become a model region for sustainable agriculture in Türkiye.

THE CARBON BORDER ADJUSTMENT MECHANISM (CBAM) AND TURKISH AGRICULTURE: A SUSTAINABLE TRANSITION

Serkan EKER, Ebru ÇOKAY

ABSTRACT

The European Union introduced the Carbon Border Adjustment Mechanism (CBAM) in 2023 to prevent "carbon leakage" and ensure fair competition under its Emissions Trading System (ETS). While initially covering carbon-intensive sectors like cement and iron-steel, CBAM's inclusion of nitrogenous fertilizers already impacts agricultural production costs. Furthermore, ongoing EU consultations suggest a high probability of CBAM's direct expansion to processed or new product groups, explicitly mentioning agricultural commodities. For Turkey, a major agricultural exporter to the EU, this presents a critical challenge. To manage this pressure, the paper proposes a dual approach. First, implementing data-driven emission reduction strategies such as precision fertilization, nitrification inhibitors biochar application, and renewable energy integration in greenhouses. Second, establishing robust digital Monitoring, Reporting, and Verification (dMRV) infrastructure, leveraging satellite imagery and IoT sensors to streamline compliance. In conclusion, while CBAM does not yet directly cover agricultural products, its indirect effects are already felt, and direct inclusion is increasingly likely. Proactive adoption of low-emission technologies, institutionalizing digital traceability, and aligning national policies with CBAM are imperative for Turkey to maintain competitiveness and achieve climate goals, transforming the "carbon wall" into a catalyst for sustainable agricultural transition.

Keywords: Agriculture, Carbon Border Adjustment Mechanism, Emissions Trading System, Greenhouse Gas Emissions,

INTRODUCTION

The European Union's Carbon Border Adjustment Mechanism is the world's first seminal regulatory instrument to offset carbon leakage to boost global climate ambition by imposing a levy on the carbon value of imported goods (Lin & Zhao, 2023). Formally enforced in May 2023, the CBAM is aimed at making the carbon price of domestic EU manufacturers falling under the Emissions Trading System equivalent to that of foreign rivals to promote global decarbonization (Perdana et al., 2023). First targeting industries of specific carbon intensity such as cement, iron, steel, aluminum, fertilizers, and electricity, the CBAM is the flagship of the European Green Deal to cut greenhouse gases by 55% by 2030 from 1990 levels, and by 2050 to be carbon neutral (Perdana & Vielle, 2022). The regulatory instrument has marked the onset of its transition period from October 1, 2023, for all incoming importers to report the innate carbon emissions for the first report period ending on January 31, 2024 (Fermeglia, 2023). From 2034, implementation in full swing including imposing of financial levies is to kick in, hence becoming the crucial economic impetus for producers to adopt less carbon-based technologies as part of the mitigation of global climate change (Wang et al., 2024). Although originally

only large industries were to be under the realm of work to be done, the fact that nitrogenous fertilizers are under the jurisdiction of the CBAM already directly impacts the production costs of agriculture, particularly for large agro-exporters of the EU such as Turkey (Kalpakchiev et al., 2023). Its implication already poses serious questions to the viability of Turkish products that are agricultural in nature, therefore necessitating the undertaking of forced reappraisal of hitherto agronomic operations and supply chains' carbon footprint to ensure sustainable access to the markets and yet remain economically viable (Guepie et al., 2023; Zhu et al., 2024). Moreover, ongoing consultations at the EU report a firm possibility that CBAM will be extended directly to processed agri-commodities and other product groups, potentially through a distinct "Agriculture-CBAM" regime (Kalpakchiev et al., 2023). Such extension would broaden the scope of carbon taxing significantly, from today's energy-based industries to the supply chains of agri-commodities, necessitating proper carbon accounting and abatement actions by agri-producers (Perdana & Vielle, 2022; Shuai et al., 2025). The analysis investigates the multi-faceted effects of the CBAM, particularly its potential extension to the agri-sector, for Turkey, the significant trading partner of the EU.

Potential Expansion of CBAM to Agriculture

The current negotiations within the European Union to expand the coverage of the Carbon Border Adjustment Mechanism to agri-food staples is a historic moment in international climate policy, extending its reach from industrial sectors to the complicated record of agri-food production and trade. It is spurred by large greenhouse gas emissions from farms, particularly from synthetic fertilizers and livestock, and would aim to avoid carbon leakage from the agri-food industry (Benedetti et al., 2025). It would need strict methodologies to estimate embedded carbon in agri-products, complicated by regionality of farm activities, local climate variations, and changing supply chains. It would require rigorous understanding of agri-carbon footprints that would consider everything from manure handling to farm practices to energy use at farm businesses, making the compliance space even more challenging for non-EU suppliers (Kolev, 2021). The potential "Agriculture-CBAM" regime could impose another 3-12% cost to non-EU agri-food suppliers, seriously jeopardizing access to markets and competitiveness for countries like Turkey (Ministère de l'Agriculture et de la Souveraineté alimentaire, 2024). It is another call to urgency for Turkish agri-food producers to bring innovative, low-carbon farm practices and to estimate and report their own emissions with precision to stay ahead of the curve in the EU market. Use of Digital Monitoring, Reporting, and Verification (dMRV) technologies that incorporate satellites and IoT sensors will be critical for compliance streamlining and could reduce verification costs by up to 40%. Such advances would facilitate more reliable carbon accounting that would enable producers to gain competitive advantages by demonstrating verifiable reduction of their environmental footprint. Such strategic investment in dMRV infrastructure and the development of a "digital carbon passport" would allow Turkey to credibly demonstrate the lowered carbon intensity of its agricultural products and therefore minimize potential trade barriers and gain wider market access in the EU. Moreover, the development of a national ETS for Turkish agriculture, including a voluntary pilot program by 2026-2028, will provide a key template for standardizing the data and creating common methodologies for carbon accounting, in harmony with international best practice. Such forward-looking approach will not only allow Turkish agriculture to be prepared for potential CBAM expansion but also facilitate the development of a more sustainable and resilient food system and contribute to addressing climate change at the international level. Such strategic coordination at the national and international levels, particularly through harmonized mechanisms of carbon accounting and reporting, would be important to ensure that Turkey would be capable of maintaining and consolidating its role as principal agricultural supplier to the European Union, while at the same time propelling its own domestic decarbonization agenda.

Implications for Non-EU Exporters

Non-EU export nations, especially those with significant agri-food trade to the EU, must rigorously reassess their supply chain and production processes as the Carbon Border Adjustment Mechanism (CBAM) potentially expands. This requires major investments in low-carbon technologies and the maintenance of tough, verifiable carbon emission records to ensure compliance and avoid punitive duties (Benedetti et al., 2025). This process necessitates that countries strengthen their carbon accounting capabilities, invest in green technologies, and adapt quickly to international policies. This builds resilience against policy risks and price volatility (Ren et al., 2025). Countries like Turkey, which have large trade exposures to the EU and carbon-intensive agri-food facilities, are particularly vulnerable to the externalities enforced by CBAM, risking a loss of competitiveness and trade imbalances (Çelik et al., 2025). Therefore, it is an urgent necessity for Turkey to invest strategically in decarbonization projects and to create national regimes that align with or mirror EU carbon pricing mechanisms to offset the negative economic impacts of CBAM (Dy & Yang, 2025). Strategically aligning national and international climate policies, particularly through common carbon reporting and accounting mechanisms, will be indispensable for Turkey to maintain and strengthen its role as a key agri-supplier to the European Union while simultaneously pursuing its own domestic decarbonization goals. Such measures aim to keep Turkish agri-products competitive by minimizing the financial costs of CBAM, thereby guaranteeing market access and trade relationships with the EU (Dy & Yang, 2025). Furthermore, developing a digital carbon passport platform will become essential for transparently revealing the embedded carbon of agri-products, building trust and facilitating smoother trade flows in an increasingly carbon-regulated global trade landscape.

TURKEY'S ROLE AS A MAJOR AGRICULTURAL EXPORTER TO THE EU

Turkey, which exports a lot of high-value agricultural goods to the European Union, is especially vulnerable to the economic effects of the Carbon Border Adjustment Mechanism (CBAM) (Raihan et al., 2023). This risk could grow if CBAM is expanded to include more agricultural products beyond just fertilizers, which would affect an even larger share of Turkish exports. The challenge is made worse by Turkey's heavy trade reliance on the EU and its use of carbon-intensive farming methods (Çelik et al., 2025). Although Turkey's exports to the EU may cut carbon emissions by 2.9%, it could also lead to a 0.8% drop in export value (Çelik et al., 2025). This shows why it's urgent for Turkey to improve its farming policies and practices to limit negative effects and stay competitive in the EU market. As the EU's sixth-largest trade partner, with €93 billion in exports, Turkey is at high risk from CBAM due to its industries' high carbon emissions (Çelik et al., 2025). This makes it necessary for Turkey to update its industrial and farming policies to match the EU's climate goals and protect its exports (Perdana et al., 2023). In the long run, CBAM could be a key driver for Turkey to speed up its shift to greener farming by adopting more sustainable technologies and methods (Çelik et al., 2025). Doing this will not only reduce short-term losses from CBAM but also help Turkey keep access to EU markets and make its agriculture more sustainable globally (Wang et al., 2024).

STRATEGIES FOR EMISSION REDUCTION AND COMPLIANCE IN TURKISH AGRICULTURE

To minimize the economic shock of the Carbon Border Adjustment Mechanism (CBAM) to its agriculture sector, Turkey needs a twin-track approach: adopting advanced low-emission technologies and establishing a credible digital and policy infrastructure to support them. This integrated structure will enhance transparency, accuracy, and compliance with international carbon accounting protocols

(Khalil et al., 2024; Çelik et al., 2025). The policy will enable Turkish industry to estimate its carbon footprint accurately, gain competitive footing within the EU market, and be in line with international efforts to minimize agricultural emissions (Raihan et al., 2023; Schaper et al., 2025).

TECHNOLOGICAL AND AGRONOMIC PRACTICES

A proactive strategy focused on advanced agricultural practices is essential for mitigating the sector's carbon footprint, enhancing resource efficiency, and securing its competitive position in international markets (Baccour et al., 2021; Piras et al., 2023).

Precision Agriculture and Fertilization: Implementing precision agriculture is a critical step to reducing nitrous oxide (N₂O) emissions and conserving water. The use of IoT sensors and AI analytics allows for variable-rate fertilization and localized irrigation, supplying precise doses of fertilizers and significantly reducing over-application (Ogwu & Kosoe, 2025). The use of nitrification inhibitors further reinforces this by blocking the microbial activities that lead to N₂O release from fertilized cropland soils, thereby enhancing nitrogen use efficiency (Pino et al., 2023; Fuerst et al., 2025).

Biochar Application for Carbon Sequestration: Biochar, a long-lasting form of charcoal produced from biomass, is a powerful climate change mitigation technology (Duku et al., 2011). It sequesters carbon in soils for centuries while concurrently improving soil fertility, water-holding capability, and microbial activity (Khan et al., 2024). This dual advantage makes biochar a key component for sustainable intensification and CBAM compliance (Ansari et al., 2023).

Renewable Energy Integration: Greenhouses, which are energy-intensive, can have their carbon footprint significantly reduced by integrating renewable energy sources like solar photovoltaics and geothermal setups (Piras et al., 2023). This strategic shift not only decreases the carbon intensity of agricultural commodities but also improves the long-term energy security of Turkish agro-industries (Mirzamohammadi et al., 2020). State policies and incentives for practices like agrivoltaics can accelerate this transition by optimizing the use of arable land for both energy and food production (Hsu & Yang, 2024).

However, the dissemination of these technologies presents significant implementation challenges, particularly for small and medium-sized farmers, such as high initial investment costs and the need for technical knowledge. Therefore, the success of technological transformation depends not only on financial incentives but also on strong collaboration and widespread training programs among farmer associations, universities, and technology providers.

POLICY AND INFRASTRUCTURE STRATEGIES

Technological adoption must be underpinned by a robust national framework that includes a credible digital Monitoring, Reporting, and Verification (dMRV) system and policies aligned with EU standards.

Digital MRV and the Carbon Passport: Establishing an effective dMRV system is essential to transparently quantify and report greenhouse gas levels. This system would use remote sensing, blockchain technology, and IoT sensors to provide real-time, tamper-proof data on emissions and sequestration rates (Khalil et al., 2024; Łękawska-Andrinopoulou, L., et al. 2024 Benedetti et al., 2025;). The core of this infrastructure would be a "digital carbon passport" platform to transparently

demonstrate the embedded carbon of agricultural products, thereby establishing credibility for smoother trade under CBAM (Su et al., 2024; Çelik et al., 2025).

Integration with *TARBİL*: Incorporating this digital passport system into existing national agricultural platforms like *TARBİL* is crucial to leverage current data infrastructure for the auto-collection and verification of carbon footprint data. This enhances traceability and transparency throughout the supply chain.

Facilitating CBAM Declarations: A verified digital passport system will ease the generation of CBAM statements by programmatically retrieving carbon intensity data, significantly reducing administrative costs for exporters and helping them achieve a sustainable competitive edge (Benedetti et al., 2025; Dy & Yang, 2025).

Aligning National ETS with EU Standards: To mitigate the financial impact of CBAM, Turkey must align its national policies with the EU. This involves expanding its domestic Emissions Trading System (ETS) to include a voluntary pilot phase for agricultural emissions, mirroring mechanisms in the EU (Peng et al., 2024; Ceschia & Soussana, 2021). This strategic alignment will reduce the financial burden on Turkish exporters and incentivize domestic decarbonization efforts (Benedetti et al., 2025). This coordinated national response, supported by bilateral agreements on carbon credit recognition, will be crucial for ensuring a smooth transition (Çelik et al., 2025).

Accessing Green Finance: A transparent and traceable carbon data system will facilitate Turkish agricultural producers' access to green financing and climate-friendly capital (Adewusi et al., 2023). This data openness, enabling the automatic creation of digital product passports, is increasingly important for market access and sustainability demonstration (Zhang & Seuring, 2024). To achieve this goal, it is critical to implement concrete financial incentive mechanisms such as "tax reductions for precision agricultural equipment," "grant programs for renewable energy installations," and "green loan opportunities for farmers engaged in low-carbon production."

This comprehensive approach, combining proactive engagement with the EU and strategic domestic policy alignment, can transform CBAM from a trade challenge into a catalyst for innovation and sustainable growth in Turkish agriculture (Zhu et al., 2024).

CONCLUSIONS

This analysis shows how the European Union's Carbon Border Adjustment Mechanism (CBAM) could seriously impact Turkish agriculture. The inclusion of nitrogen-based fertilizers under CBAM is already raising production costs, and future expansions to other processed agricultural goods could make things even more challenging.

Turkey is especially exposed to these new regulations. Still, this also presents an important opportunity. Turkey can use this moment to move toward a more sustainable, low-carbon farming model. Doing so would help protect access to EU markets and make Turkish agricultural exports more competitive globally as environmental concerns grow. To succeed, Turkey needs strong policies that include financial support, training for farmers, and environmental regulations. It's also essential to have reliable systems in place to measure and report emissions. With its new Emissions Trading System (ETS) and digital tools, Turkey can show clear progress in reducing agricultural emissions. By taking action, Turkey can turn the challenge of CBAM into an opportunity for long-term change.

This shift would help make Turkish agriculture more sustainable, protect jobs and exports, and support climate goals at home and abroad.

ABSTRACT

Tomatoes are the most widely grown vegetable in the world. Viral diseases are among the main causes of limited tomato production both globally and in our country. Intensive cultivation raises the risk of viral and fungal diseases, such as Tomato Yellow Leaf Curl Virus (TYLCV), Tomato Spotted Wilt Virus (TSWV), and root and root collar rot (*Fusarium oxysporum* f. sp. *radicis-lycopersici*, or FORL), which can cause substantial economic losses in tomato-growing areas. Identifying disease-associated gene regions in tomato plants is a crucial and groundbreaking step in this research area. These identifications, accomplished through molecular markers, aim to create a strong foundation for discovering disease-resistant tomato varieties and contributing to our country and globally. The slow pace and limitations of traditional breeding methods have highlighted the importance of molecular markers. Marker-assisted selection (MAS) allows for the detection of gene regions linked to disease resistance and the integration of these genes into the plant's genome for early selection. Molecular markers, especially SSR, SCAR, and CAPS types, are effectively used in tomato breeding programs and have largely replaced conventional testing. Recent research has led to the development and use of numerous molecular markers to identify resistance genes, like Ty-1 and Ty-3 against TYLCV, Sw-5 against TSWV, I-1 and I-2 against *Fusarium*, and Mi against nematodes. These markers help in screening local genotypes and wild tomato species, facilitating the evaluation of genetic resources. According to the review for this thesis, incorporating molecular markers into breeding programs offers significant benefits, saving time, effort, and costs. It also provides faster, more reliable results compared to traditional methods. Additionally, developing plant lines with multiple resistance genes is essential to protect the production capacity of tomatoes in the face of climate change and mounting disease pressure. In conclusion, the widespread use of the MAS method greatly contributes to developing new, resistant tomato varieties and aligns with sustainable agriculture goals.

Keywords: Tomato, disease, virus, molecular marker

INTRODUCTION

Tomatoes (*Lycopersicon esculentum* L.) belong to the Solanaceae family and the Solanum genus. They are native to South America. It was first discovered in Mexico. The cultivated species was first brought to Europe by the Spanish in the 16th century and from there introduced to South and East Asia, Africa, and the Middle East, eventually spreading worldwide. (Hassan, 2020). According to data from the Food and Agriculture Organization of the United Nations (FAO), Turkey ranks third in the world in tomato production with approximately 13 million tons as of 2022, following China and India (FAO, 2025). According to TÜİK data, Turkey's vegetable production in 2023 is approximately 31.8 million tons. Tomatoes, the most produced vegetable in Turkey, account for 40.88% (13 million

300 thousand tons) of the total vegetable production in 2023 in terms of production volume. When Turkey's tomato cultivation areas are ranked by province in 2023, Bursa is in first place with approximately 19,000 hectares. Antalya follows with approximately 17,000 hectares and Konya with 14,000 hectares in 2023. When looking at tomato production by province, Antalya ranks first with a 19.6% share. Antalya is followed by Bursa with an 11.5% share and Manisa with an 8.2% share (TÜİK, 2025).

In addition to being one of the most widely cultivated vegetables worldwide, tomatoes are used as raw material in human nutrition and various industrial sectors (Kızmaz, 2024). In addition to their taste, tomatoes are rich in vitamins A and C, as well as minerals such as calcium, potassium, and phosphorus, making them suitable for both direct human consumption and as a raw material for industrial products such as ketchup, sauces, and canned goods (Sainju and Dris, 2006; Ayisha et al., 2017). This is due to its widespread cultivation worldwide, its adaptability to ecological conditions enabling its cultivation in different geographical regions, the availability of various forms of use, both fresh and processed, and its prominence as a healthy product in meeting people's fresh vegetable needs. Since the world population is projected to increase by 50% by 2050, an increase in tomato production is expected, as with all products (Aktas et al., 2021).

Tomatoes (*Solanum lycopersicum* L.) are an economically important vegetable crop worldwide, but their production is seriously threatened by diseases and pests. (Yang et al., 2025). Many plant species and varieties have resistance to one or more diseases and pests. Hybrid varieties used in vegetable production, in particular, have multiple resistances. (Pinar et al., 2013). To date, 15 resistance genes have been transferred to tomatoes cultivated from various sources (Barone, 2004). Tomato (*Solanum lycopersicum* L.) production faces significant yield losses due to biotic stresses. The development of genetically resistant varieties offers a sustainable alternative to chemical controls, which are often costly and ineffective. (Hussain et al., 2025). Since the early 20th century, disease and pest resistance has been transferred to cultivated varieties using classical breeding methods. However, resistance to a single factor is insufficient for tomatoes, which are intensively cultivated, have a high number of diseases and pests, and are an important vegetable crop. Under current conditions, at least three or more disease and pest resistances are required depending on the production area and time. As the number of required resistances increases, the breeding period lengthens and may even become impossible. (Pinar et al., 2013).

As with other crops, diseases in tomato cultivation cause significant economic losses. Among these, viral diseases are considered the most important pathogens limiting tomato production, with 312 viruses and viroids (22 families and 39 genera) associated with tomato plants identified to date. Important viruses include species belonging to the Begomovirus, Tospovirus, Cucumovirus, Potyvirus, and Tobamovirus genera (Kızmaz, 2024).

Tomato yellow leaf curl virus (TYLCV) is responsible for tomato yellow leaf curl disease (TYLCD) and causes a significant decline in tomato (*Solanum lycopersicum* L.) yields worldwide. The use of resistant varieties is advocated as a sustainable management strategy. Significant progress has been made in genetically characterizing tomato resistance genes (R genes). Tomato breeding for TYLCV resistance has primarily relied on the introgression of the race-specific resistance gene Ty-3, which originates from wild tomato species. The improvement or development of a cultivated variety can be achieved using marker-assisted selection (MAS). Therefore, the precise and easy use of gene-targeted markers is of great importance for selection in breeding programs (Adedze et al. 2018).

Viral Diseases and Related Resistance Genes

Tomato Yellow Leaf Curl Virus (TYLCV): TYLCV is a DNA virus transmitted by whiteflies (*Bemisia tabaci*) that causes serious yield losses in tomato production. Six different resistance loci, Ty1, Ty2, Ty3, Ty4, Ty5, and Ty6, have been identified against this disease. Most of these genes have been transferred from wild species such as *S. chilense* and *S. habrochaites*. It has been determined that the Ty1 and Ty3 genes are allelic, and the Pelota (Pelo) gene has been identified for Ty5, leading to the development of a functional dCAPS marker (Lapidot et al., 2015).

Tomato Spotted Wilt Virus (TSWV): The most commonly used resistance gene against this disease, which belongs to the Tospovirus group, is Sw-5. This gene, which originates from *S. peruvianum*, interacts with Avr genes to induce a hypersensitive response. SNP and SCAR markers have been identified for the Sw-5b allele (Van Zijl et al. 1985; Stevens et al. 1991).

Tomato Mosaic Virus (ToMV): The Tm-1 and Tm-22 genes, which provide resistance to this disease, were obtained from *S. habrochaites* and *S. peruvianum*, respectively. The Tm-22 allele is a more resistant and widely used form (Pelham, 1966; Young and Tanksley 1989).

Fungus-Caused Diseases

Verticillium wilt: The Ve1 and Ve2 genes have been identified as conferring resistance to this disease caused by *Verticillium dahliae*. The Ve1 gene encodes a receptor protein with an LRR structure and is characterized by a single base deletion that determines its function (Jung et al., 2015).

Fusarium wilt: The I1, I2, I3, and I7 genes have been identified as conferring resistance against *Fusarium oxysporum*. The I-2 and I-3 genes have an NB-LRR structure and play an important role in genetic resistance (Lim et al. 2006; Gonzalez-Cendales et al. 2015).

Late Blight: Two resistance genes, Ph2 and Ph3, have been identified against the pathogen *Phytophthora infestans*. The Ph3 gene is a functional resistance locus of high importance, detectable using SCAR markers (Black et al. 1996; Kim and Mutschler 2006; Zhang et al. 2013).

Leaf Mold: Resistance genes such as Cf-2, Cf-4, Cf-5, and Cf-9 have been identified against the pathogen *Cladosporium fulvum*. Cf genes typically encode LRR proteins, which interact with the fungus's Avr proteins to induce a hypersensitive response (Jones et al. 1994; Dixon et al. 1996; Thomas et al. 1997; Dixon et al. 1998; Takken et al. 1999).

Nematode-Caused Diseases

Root-knot nematodes (*Meloidogyne* spp.): The Mi-1 gene is the most commonly used resistance gene against this pathogen. The Mi-1.2 allele is a functional form that provides resistance against both nematodes and certain harmful insects (Milligan et al., 1998).

Bacterial Diseases

Bacterial Spot: Various resistance genes such as Rx-1, Rx-3, Rx-4, Xv3, Xv4, and Bs4 have been identified against this disease caused by *Xanthomonas* spp. These genes activate the plant's immune system by recognizing Avr proteins from different strains (Schornack et al., 2004).

Bacterial Speck: The Pto gene has been identified as resistant to *Pseudomonas syringae* pv. *tomato*. Pto triggers the defense response in plants by recognizing the bacterial effectors AvrPto and AvrPtoB. It works in conjunction with the PRF gene to facilitate signal transduction (Kim et al., 2002; Abramovitch et al., 2006).

THE USE OF MARKER-ASSISTED SELECTION IN PLANT BREEDING

Molecular markers have been used extensively in many plants since the 1980s. In particular, markers linked to disease resistance genes have been developed and used in breeding programs for tomatoes (Pinar et al., 2013).

The Marker-Assisted Selection (MAS) Paradigm in Plant Breeding Molecular marker-assisted selection (MAS) is an approach developed to address issues associated with traditional plant breeding, utilizing multiple DNA markers to identify genomic regions responsible for the expression of desired traits in plants. With the development of DNA markers in the late 1970s, breeding programs shifted direction, and the use of markers linked to the desired gene provided a significant advantage (Brumlop et al., 2011). Additionally, it has become an economically important technique that saves time in identifying plants with desired traits (Kanlitepe et al., 2010).

Molecular markers are not affected by environmental conditions and can be detected at all stages of plant growth, thereby enabling significant progress in identifying genotypes that cannot be detected due to environmental effects (Francia et al., 2005). On the other hand, since many genotypes with undesirable traits will be separated using MAS, it is possible to create a more effective breeding program (Karakaş and Bayrıl, 2024). To date, more than 40 genes (single genes and QTLs) have been mapped. These mapped traits are utilized in breeding programs using the MAS method. Since 1990, the MAS method has been used in breeding programs alongside classical breeding methods. The reasons for using MAS include shortening the breeding period through early selection, facilitating the transfer of resistance through backcrossing, determining the linkage between genes, facilitating the identification of traits that are difficult to screen, and eliminating the need for testing for resistance to certain diseases and pests under quarantine, thereby enabling work with a smaller number of plants and providing advantages in terms of labor and cost (Pinar et al., 2013).

Molecular markers are any gene region or DNA fragment associated with a gene region in the genome. Molecular markers are known as DNA markers because they constitute the DNA-based type of genetic markers. DNA markers are markers that reveal DNA sequence differences between different genotypes in various ways. The use of nucleic acid-based genetic markers in genome analysis is an area of need for breeders. These markers can be used to distinguish and identify crop varieties that are morphologically very similar to each other (Yorgancılar et al., 2015).

LITERATURE REVIEW

Altundas et al., (2024) determined that 12 of the 17 pink tomato hybrids developed as a result of their study were resistant to all of the TSWV, TYLCV, Fol-1/2/3, ToMV, M, and Vd pathogens.

The 12 pink hybrid tomatoes resistant to all the diseases examined were treated with Fe-DTPA at concentrations of 0, 150, 300, and 600 $\mu\text{mol L}^{-1}$ under greenhouse conditions. When the plants reach full maturity, leaf and fruit samples will be collected, and Fe concentrations will be determined using inductively coupled plasma/optical emission spectrophotometry (ICP-OES). The Fe concentrations in the green parts and fruits of the plants will be compared to calculate Fe uptake and translocation efficiency. This will enable the development of tomatoes with the highest Fe concentration, Fe uptake, and translocation efficiency.

The study by Basım and Kandil, (2024) focuses on the cultivation of cluster tomato varieties resistant or tolerant to *Fusarium oxysporum* f.sp. *radicis-lycopersici* (FORL) and Tomato Yellow Leaf Curl Virus (TYLCV) using molecular DNA markers. The breeding program involves isolating genomic DNA from 69 cluster tomato varieties and then using PCR with C2-25 and Ty3P6-25 primers to determine which varieties are resistant or tolerant to FORL and TYLCV, respectively. The results of the tests demonstrated that DNA molecular markers can reliably determine the presence of resistance or tolerance to FORL and TYLCV in cluster tomatoes. Molecular markers have shown the potential to efficiently screen thousands of tomato plants in a shorter time, enabling the selection of higher-quality, resistant, or tolerant varieties.

El Mohtar et al., (2007) developed a marker for the I-2 gene, which confers resistance to *F. oxysporum* f. sp. *lycopersici* race 2. The I-2 gene responsible for resistance to this race was detected in 39 out of 40 tomato genotypes known to be resistant to the same race, while only one tomato genotype did not show the band associated with the I-2 gene. The validity of this method has been reported to be maintained in studies conducted in three different countries using molecular and classical testing.

This study, conducted by Facundo-Angel et al. (2024), was carried out to identify resistance genes against pathogens commonly found in tomato (*Solanum lycopersicum* L.) cultivation. In the study, the presence of genes conferring resistance to important pathogens such as *Meloidogyne* sp., *Fusarium oxysporum*, *Stemphyllium* sp., *Phytophthora infestans*, TYLCV, and TSWV was evaluated in 20 tomato genotypes using 10 different SCAR-type molecular markers. As a result of the study, resistance genes were identified in 17 advanced lines and 3 commercial hybrids. This indicates that the aforementioned markers can be effectively used in selection processes and offer a faster, more economical, and reliable alternative compared to conventional breeding methods. The findings support the applicability of molecular marker-assisted selection (MAS) in tomato breeding programs.

In their study, Hussain E. et al., (2025) used SSR, SCAR, and CAPS markers to assess resistance against six major diseases, including *Fusarium* wilt, late blight, bacterial wilt, root-knot nematode, *Tomato Mosaic Virus* (ToMV), and *Tomato Yellow Leaf Curl Virus* (TYLCV). The study analyzed 964 tomato samples, including both wild germplasm (371) and varieties (593). The results emphasize that wild germplasm has significantly higher resistance levels than cultivated tomatoes, making it an invaluable resource for breeding programs.

Kahraman (2017), in his doctoral thesis titled “Development of Tomato Strains Resistant to *Tomato Spotted Wilt Virus* and Root-Knot Nematodes through Molecular Marker Selection in Tomatoes,” aimed to pyramid the Sw-5 gene, which confers resistance to the *Tomato Spotted Wilt Virus*, and the Mi genes, which confer resistance to soil-borne root-knot nematode species. As a result of the study, resistant advanced breeding lines were developed. Thirty advanced breeding lines resistant to the *Tomato Spotted Wilt Virus* at the F4 stage and 100 advanced breeding lines

homozygous resistant to TSWV and nematodes at the F4 stage were developed. These lines can be used as references in future molecular and biological testing studies and as parent lines in variety development studies.

Mortazavi et al., (2025) in this study, genetic resistance to root-knot nematode (RKN), which causes significant yield losses in tomato (*Solanum lycopersicum* L.) cultivation, was investigated. A total of 212 tomato genotypes collected from different geographical regions (Turkey, France, Taiwan, USA, Germany, Kyrgyzstan, etc.) were molecularly screened using the Mi23 primer pair (Mi23-F/Mi23-R) to determine the presence of the Mi-1.2 resistance gene. According to the results, a 380 bp band was observed in only six genotypes, and three of these genotypes (Romitel-RHT 3, AVTO0102-CLN2366B, and AVTO0101-CLN2413D) were homozygous, while three (Aysbars-F1, Italian Field [To-23], and Red Pole [To-25]) were determined to be heterozygous resistant. In the remaining 206 genotypes, the resistance gene was not detected, and these genotypes were found to be susceptible to the nematode. These findings demonstrate how effective and critical molecular markers are as tools in identifying resistance genes and developing disease-resistant tomato varieties. The study provides important genetic material for increasing nematode resistance in breeding programs.

Oğuz, (2010) investigated the resistance of tomato genetic resources and some wild genotypes to the pathogen morphologically and molecularly in Turkey. The control was LA 3667, which carries the TSWV resistance gene Sw-5, Formula F₁, and *S. peruvianum* genotypes carrying the TSWV resistance gene Sw-5 as a control. The study concluded that all local genotypes were susceptible to the pathogen.

In the research article titled “Use of Molecular Markers in the Development of Disease- and Pest-Resistant Lines and Varieties in Tomatoes” published by Pinar et al. (2013), multiple markers were tested for a single gene to assess nematode resistance. -23 SCAR markers were used to test for nematode resistance, the Ve2 2720F SCAR marker for *Verticillium* wilt, the At2-F3R3 SCAR marker for the I-1 gene conferring resistance to Fusarium wilt, the TAO901 CAPS marker for the I-2 gene, the JB-1 CAPS marker for the Ty-1 gene, the P6-25 SCAR marker for the Ty-3a gene, and the Sw-5.2 SCAR marker for the Sw-5 gene. It has been demonstrated that these molecular markers could serve as an alternative to classical testing in the development of disease- and pest-resistant varieties and lines.

Pinar et al., (2013) screened 450 tomato lines for resistance to *F. oxysporum* f. sp. *lycopersici* using SCAR and CAPS markers developed based on the I-1 and I-2 genes. Eighty-eight tomato lines produced the resistance allele band for the I-1 gene, and 74 lines produced the resistance allele band for the I-2 gene. As a result, it was reported that molecular markers (I-1 and I-2) determining resistance to *F. oxysporum* f. sp. *lycopersici* could be used in breeding programs to develop Fusarium-resistant varieties, thereby enabling the evaluation of more material.

In this study conducted by Yang et al. (2025), 401 tomato samples were analyzed using gene-related molecular markers to identify disease resistance genes in tomato (*Solanum lycopersicum* L.) germplasm. The study evaluated the presence of 21 genes conferring resistance to 10 different diseases, with the frequency of these genes varying between 0.2% and 66.1% across the samples. The I-1, I-2, Sm, Tm-2a, and Ph-3 genes were detected at the highest frequency, while the frequencies of the Ty-2, Ty-4, Mi-HT, I-3, and Tm-2 genes were found to be quite low. 86.3% of the tomatoes examined carried at least one disease resistance gene, with gene frequency and distribution being higher in modern processing and fresh consumption lines and lower in Latin American local varieties

and old varieties. In terms of marker reliability, CAUTy4 and 18IY13 had the highest accuracy rate (100%) for the Ty-4 gene, while the reliability of markers used for the Ty-2 gene was quite low (44.4%). Field observations confirmed the accuracy of marker-assisted gene detection to a large extent. The study demonstrated that disease resistance genes can be reliably identified using markers and that this genetic information can be effectively utilized in tomato breeding programs.

In Zengin, (2016) doctoral thesis, marker-assisted selection breeding in tomatoes was used to develop lines containing multiple resistance genes against Tomato Yellow Leaf Curl Virus (TYLCV), Tomato Spotted Wilt Virus (TSWV), nematodes, and Root and Crown Rot (FORL). As a result, the Institute's four different types of sensitive tomato lines (BATEM1, BATEM2, BATEM3, and BATEM4) were crossed with a resistant F1 tomato variety (Tayfun F1), resulting in the creation of 95 genotypes at the F3 stage through selection based on both disease resistance and agronomic characteristics. These lines, which have good agronomic and morphological characteristics and different combinations of resistance to the aforementioned diseases and nematodes, have been added to the BATEM tomato gene pool.

RESULTS

In this study, gene regions providing resistance to the main biotic stress factors limiting tomato (*Solanum lycopersicum* L.) production were evaluated using molecular markers, and the effectiveness of marker-assisted selection (MAS) methods in breeding programs was demonstrated. SSR, SCAR, and CAPS-type markers used to determine resistance to important pathogens such as TYLCV, TSWV, FORL, and root-knot nematodes successfully identified multiple resistance genes in different tomato lines. Research indicates that the molecular marker-assisted selection (MAS) method offers numerous advantages over classical breeding methods in the process of acquiring resistance to tomato diseases. The time-consuming and costly nature of classical breeding methods, as well as the difficulties encountered when transferring multiple resistance genes simultaneously, are significantly reduced through the use of molecular markers. In particular, the ability to perform early selection and the detection and screening of genes before they are phenotypically expressed both accelerate the breeding process and ensure more efficient use of resources. This not only provides significant economic and labor-saving benefits but also guarantees the stable transfer of resistance genes into lines. Resistance genes such as Ty genes (Ty-1, Ty-3) against TYLCV, Sw-5 against TSWV, I-1 and I-2 genes against Fusarium, and Mi-1 against nematodes, which are addressed in the study, are successfully identified using molecular markers, thereby enabling the pyramiding of targeted resistance genes. This pyramiding strategy increases the tomato's resistance to multiple diseases and pests, helping to protect the plant's production potential against challenging conditions such as climate change and increasing disease pressure. Literature reviews and experimental studies have shown that molecular markers play a vital role in the introgression of genetic resources from wild tomato species into cultivated tomatoes. Resistance genes found in wild species can be rapidly and reliably transferred to cultivated varieties using molecular markers, thereby increasing genetic diversity and resistance profiles. This not only enhances the resistance capacity of existing varieties but also provides a critical resource for the development of new resistant varieties. As a result, the integration of molecular markers into tomato breeding programs is considered a significant turning point in the development of disease-resistant varieties. This approach is consistent with sustainable agriculture and food security goals, contributing to the spread of environmentally friendly production techniques by reducing dependence on chemical control. Additionally, resistant varieties developed using the MAS method reduce economic losses for producers while enabling the provision of healthier and higher-quality tomato products to consumers.

In future studies, the development of molecular markers using more precise, high-yield, and cost-effective tools, along with the discovery of new resistance genes, will further advance disease management in tomato production. Furthermore, the development of lines carrying multiple gene resistances will offer long-term solutions against new disease threats shaped by climate change. Therefore, the conservation of genetic resources and the support of molecular breeding techniques through multidisciplinary approaches are of vital importance for the sustainability of tomato production.

CONCLUSIONS

This study highlights the effectiveness of molecular marker-assisted selection (MAS) in improving tomato resistance to major pathogens. Compared to conventional breeding, MAS enables rapid and reliable identification, transfer, and pyramiding of key resistance genes (e.g., *Ty*, *Sw-5*, *I*, *Mi-1*), while facilitating the use of wild genetic resources. This approach accelerates breeding, reduces reliance on chemicals, and contributes to sustainable tomato production and food security under increasing disease and climate pressures.

ABSTRACT

Reservoirs play a crucial role in freshwater ecosystems, serving key functions such as irrigation, drinking water supply, and flood control. Despite their importance, these artificial lakes are increasingly threatened by anthropogenic pollution. Macro elements like sodium (Na), magnesium (Mg), potassium (K), and calcium (Ca) are essential for both aquatic life and human health, and their elevated levels may indicate ecological stress or contamination. Atikhisar and Alibey Dam Lakes, located in the Marmara Region of Türkiye, are among the region's most vital reservoirs, supplying water to the provinces of Çanakkale and İstanbul. In this study, surface water samples were collected during the dry season of 2022 from both the inlet and outlet zones of each reservoir (a total of four sites). The concentrations of major macro elements—sodium (Na), magnesium (Mg), potassium (K), and calcium (Ca)—were measured, and potential macro elemental risks were assessed. Results indicated that Alibey Dam exhibited higher average concentrations of these elements compared to Atikhisar Dam. Overall, the elemental abundance in both reservoirs followed the trend: Na (81.066 µg/L) > Mg (31.434 µg/L) > Ca (21.867 µg/L) > K (6.353 µg/L).

Keywords: Atikhisar Dam Lake, Alibey Dam Lake, Macro elements, Water quality

INTRODUCTION

Macro elements such as sodium (Na), magnesium (Mg), potassium (K), and calcium (Ca) are essential constituents of natural waters and play vital roles in maintaining aquatic ecosystem function and water quality (Köse et al., 2013; Çiçek et al., 2013; Tokatlı and Helvacıoğlu, 2020; Ali et al., 2025). They are crucial for biological processes in both aquatic organisms and humans, including osmoregulation, enzyme activity, and bone development. However, elevated concentrations of these elements—especially under the influence of anthropogenic inputs such as agricultural runoff, industrial discharges, and urbanization—may lead to ecological imbalances and potential health risks. For instance, excessive sodium or magnesium levels can affect water taste, soil structure, and even plant and aquatic organism health. Therefore, regular monitoring of macro element concentrations in freshwater bodies is essential for early detection of pollution, sustainable water management, and the protection of ecological and human health (Arslan et al., 2012; Tokatlı et al., 2020; Din et al., 2023; Tokatlı et al., 2024; Ustaoglu et al., 2025).

Atikhisar Dam, located on Sarıçay Stream in the province of Çanakkale, was constructed between 1971 and 1975 primarily for irrigation and flood control. This earth-fill type dam has a body volume of approximately 1.99 million cubic meters and rises about 43 meters from the riverbed. Under normal water conditions, the reservoir has a surface area of 3.30 km² and a storage capacity of 40 hm³, supporting irrigation over nearly 5200 hectares of agricultural land (Anonymous, 2021a; Tokatlı et al., 2023). Similarly, Alibey Dam, situated on Alibey Stream in İstanbul, was built between 1975 and

1983 to supply drinking, utility, and industrial water. Also designed as an earth-fill dam, it has a body volume of about 1.93 million cubic meters and a height of 30 meters. The reservoir holds up to 66.80 hm³ of water and spans a surface area of 4.66 km² at normal water levels, providing approximately 39 hm³ of potable water annually for the city (Anonymous, 2021b; Varol and Tokatlı, 2024).

This study aims to assess the macro elemental composition of two strategically important reservoirs in the Marmara Region—Atikhisar and Alibey Dam Lakes—which serve as key sources of irrigation and drinking water. By focusing on the concentrations of sodium (Na), magnesium (Mg), potassium (K), and calcium (Ca), the research seeks to highlight the current status of these essential yet potentially harmful elements when present in excess. Considering the ecological significance of reservoirs and the increasing pressure from anthropogenic influences, the study underscores the necessity of regular monitoring to ensure sustainable water resource management and the protection of ecosystem and public health.

MATERIALS AND METHODS

Water samples were systematically collected from both the inlet and outlet zones of Atikhisar and Alibey Dam Lakes, comprising a total of four sampling stations, during the dry season at the end of summer in 2022. These specific locations were selected to represent potential spatial variations in water quality between the entry and exit points of each reservoir system. The geographical layout of the study area, along with the precise coordinates of the sampling stations, is illustrated in Figure 1 to provide a clear spatial reference for the sampling design and to enhance the reproducibility of the study.

For macro-elemental analysis, the pH of each one-liter water sample was adjusted to approximately 2.0 by the addition of 2 mL of concentrated nitric acid (HNO₃) to prevent precipitation and ensure element stabilization. Subsequently, the samples were filtered using cellulose nitrate membrane filters with a pore size of 0.45 µm to remove particulate matter. The filtrates were then diluted to a final volume of 50 mL with ultrapure water to standardize the analytical conditions. Concentrations of calcium (Ca), magnesium (Mg), sodium (Na), and potassium (K) were quantified using an inductively coupled plasma mass spectrometer (ICP–MS, Agilent 7700xx) at the internationally accredited laboratory of Trakya University (certified under TS EN ISO/IEC 17025). All measurements were conducted in triplicate, and the mean values were reported to ensure analytical precision and reproducibility (EPA, 2001).

Figure 1. Study area and selected sampling locations

RESULTS AND DISCUSSION

The determined macro-elemental concentrations (Ca, Mg, Na, and K) at the designated sampling locations on both Atikhisar and Alibey Dam Lakes are presented in Figure 2. These values reflect the spatial distribution of the selected elements and provide insight into the ionic composition of the water bodies during the sampling period.

Notable spatial variations were observed between the two reservoirs. Sodium (Na) levels were markedly higher in Alibey Dam Lake, reaching a maximum of 128,219 $\mu\text{g/L}$ at station AB1, whereas the lowest value (25,690 $\mu\text{g/L}$) was recorded at AH2 in Atikhisar Dam Lake. Similarly, calcium (Ca) concentrations were substantially higher at AH1 (33,837 $\mu\text{g/L}$), indicating possible geological or anthropogenic influences. Mean concentrations across all stations were calculated as 81,066 $\mu\text{g/L}$ for Na, 31,434 $\mu\text{g/L}$ for Mg, 6,353 $\mu\text{g/L}$ for K, and 21,867 $\mu\text{g/L}$ for Ca.

Figure 2. Spatial distributions of macro elements

These data suggest distinct hydrochemical characteristics between the two dam lakes, particularly with respect to the distribution of sodium and calcium. The markedly higher sodium concentrations observed in Alibey Dam Lake, compared to Atikhisar Dam Lake, may be indicative of differences in the geological composition of the catchment areas, such as the presence of sodium-rich sedimentary formations or evaporitic deposits (Hem, 1985; Gibbs, 1970). Moreover, anthropogenic factors such as agricultural runoff, domestic wastewater discharge, and land use practices—particularly irrigation with sodium-enriched water—can further contribute to elevated sodium levels in surface waters (Zhou et al., 2016). On the other hand, the relatively higher calcium content in Atikhisar Dam Lake may be attributed to carbonate-rich lithologies in the surrounding catchment or enhanced dissolution processes of calcareous materials, which are common in Mediterranean hydrological regimes (Meybeck, 1987). Additionally, inflow dynamics, including flow rate, residence time, and seasonal variability, can significantly influence the dilution or concentration of dissolved ions in reservoirs (Lerman et al., 2007). Overall, the observed elemental distribution reflects the combined influence of natural and anthropogenic processes, underscoring the importance of basin-specific evaluations in understanding freshwater chemistry.

CONCLUSIONS

In this study, surface water samples were collected from the inlet and outlet zones of Atikhisar and Alibey Dam Lakes to determine the concentrations of key macro elements (Na, Mg, K, and Ca) during the dry season of 2022. The elemental composition of these two important reservoirs, which supply water to the provinces of Çanakkale and İstanbul, was evaluated in order to assess potential ecological and water quality risks. The results revealed that Alibey Dam Lake exhibited notably higher average concentrations of all analysed elements compared to Atikhisar, suggesting greater exposure to anthropogenic inputs or distinct geochemical characteristics. Among the studied elements, sodium was found in the highest concentrations, followed by magnesium, calcium, and potassium. These findings underscore the need for regular monitoring of elemental loads in freshwater reservoirs, as elevated macroelement levels can be early indicators of ecological stress and potential threats to both aquatic ecosystems and human water use.

ABSTRACT

Turkey's diverse geography and climatic conditions contribute to a rich flora, particularly in medicinal and aromatic plants that serve as important sources for pharmaceutical, food, and cosmetic industries. *Inula graveolens* (Asteraceae) is an annual plant characterized by hairy stems and yellow flowers, widely distributed in the Mediterranean region of Turkey. Traditionally, it has been used in folk medicine for respiratory infections, cough, bronchitis, and urinary tract disorders, yet detailed studies on its chemical composition remain limited. This study aimed to determine the phenolic compound profiles of flower, aerial, and root extracts of *I. graveolens* using HPLC-DAD analysis. Plant materials were collected, dried, and separately extracted with ethyl acetate, methanol, and water. The resulting extracts were filtered through 0.20 µm membranes and analyzed against 26 phenolic acid standards. In flower extracts, luteolin (11.43 mg/g) and coumarin (8.20 mg/g) were identified as major compounds in ethyl acetate; coumarin (21.65 mg/g) in methanol; and coumarin (11.43 mg/g) in aqueous extracts. In aerial parts, luteolin (14.78 mg/g), quercetin (11.25 mg/g), and trans-cinnamic acid (7.33 mg/g) were major compounds in ethyl acetate; coumarin (18.73 mg/g) and pyrocatechol (7.38 mg/g) in methanol; and coumarin (10.85 mg/g) and pyrocatechol (6.59 mg/g) in aqueous extracts. In roots, luteolin (6.91 mg/g) was predominant in ethyl acetate; rosmarinic acid (5.20 mg/g) and coumarin (4.63 mg/g) in methanol; and pyrocatechol (3.47 mg/g) and coumarin (2.69 mg/g) in aqueous extracts. The findings indicate that *Inula graveolens* is rich in phenolic compounds, particularly luteolin and coumarin, across different plant parts, with concentrations varying according to the solvent used. The high levels of these phenolics suggest potential antioxidant and pharmacological properties. This comprehensive phenolic profile provides valuable insights into the chemical composition of *I. graveolens* and serves as a basis for future studies focusing on its bioactive potential and possible applications in pharmaceutical and nutraceutical formulations.

Keywords: *Inula graveolens*, phenolic compounds, HPLC-DAD, luteolin, coumarin

1. INTRODUCTION

Phenolic compounds are secondary metabolites produced by plants, consisting of a benzene ring with one or more hydroxyl groups and functional substituents. All plants synthesize various phenolic compounds in different types and concentrations as part of their defense mechanisms (Atak & Uslu, 2018). Although the quantity differs among plants, phenolics represent the most abundant class of secondary metabolites (Dai & Mumper, 2010). Plants tend to produce these compounds under stress conditions. In addition to their role in defense, phenolic compounds contribute to the taste and color of fruits and vegetables (Atak et al., 2017). Due to their wide range of biological activities, including antioxidant, antimicrobial, anticancer, and anti-inflammatory properties, phenolic compounds are of great pharmacological significance (Atak & Uslu, 2018).

Turkey is rich in plant and fungal diversity due to its geographical location and climatic variability. The country has a remarkable potential in medicinal and aromatic plants, as confirmed by several studies. In recent years, there has been a significant increase in scientific studies investigating the pharmaceutical, food, and cosmetic applications of these plants.

The genus *Inula*, a member of the Asteraceae family, includes over one hundred species. These plants are mainly distributed in Africa, Asia (with 20 species reported in China), and Europe, particularly in the Mediterranean region. *Inula graveolens*, an aromatic species of medicinal importance, is widely distributed in the Mediterranean region of Turkey. It grows in a broad range of habitats, from dry, rocky, mountainous areas to moist, shaded lowlands. The species is usually perennial but may also occur as annual plants (Özhan, 2012; Lack, 2007). It is characterized by sticky, hairy stems and yellow flowers, and is valued pharmacologically due to its essential oils and aromatic compounds (Afifia et al., 2015).

Historically, some *Inula* species have been used in folk medicine for treating respiratory diseases such as upper respiratory infections, cough, common cold, and bronchitis. In addition, they have been reported to support the immune system, improve acne, and treat various skin inflammations. Literature also documents their use against urinary tract infections, cystitis, nephritis, and uremia (Kılıç, 2014; Akbulut et al., 2021).

Previous studies reported that extracts of *I. viscosa*, *I. helenium* ssp. *turcoracemosa*, and *I. montbretiana* possess significant antioxidant and antimicrobial activities, attributed to their phenolic composition. Major phenolic compounds identified included chlorogenic acid, caffeic acid, rutin, myricetin, quercetin, luteolin, and kaempferol, with chlorogenic acid, luteolin, and caffeic acid being predominant depending on the species (Gökbulut et al., 2013). Further studies confirmed antiproliferative activity of *I. viscosa* extracts, with methanol extracts showing higher activity than aqueous ones, correlating with their richer phenolic and flavonoid content (Özkan et al., 2019).

For *I. graveolens*, chlorogenic acid (2167 ppb/kg), quinic acid (845 ppb/kg), and hyperoside (146 ppb/kg) were previously reported as major compounds. Mammadov et al. (2023) reported total phenolic and flavonoid contents of methanol extracts as 5.36 mg GAE/g and 3.49 mg QE/g, respectively. Kılıç (2014) identified 1,8-cineole (22.4%), borneol (20.4%), and α -cadinol (11.8%) as major volatile compounds in *I. graveolens*. Afshar et al. (2015) studied the total phenolic, flavonoid, and flavonol contents of *I. graveolens* and their antioxidant activities.

Despite these findings, comprehensive studies on the phenolic profile of *I. graveolens* remain scarce. Therefore, this study aimed to determine the detailed phenolic composition of flower, aerial, and root extracts of *I. graveolens* using HPLC-DAD analysis.

2. MATERIALS AND METHOD

2.1. Plant Material

Inula graveolens (L.) Desf. was collected during its flowering stage in late November 2022 from Kızılağaç, Ula district, Muğla Province, Turkey. Approximately 2 kg of plant material was harvested. A voucher specimen has been deposited at the Plant Chemistry Laboratory, Department of Chemistry, Muğla Sıtkı Koçman University.

2.2. Extraction

The plant material was separated into roots, aerial parts, and flowers, which were then dried in a cool, shaded, and well-ventilated place. The dried samples were extracted sequentially with solvents of increasing polarity: ethyl acetate, methanol, and hot water. After maceration, solvents were evaporated under reduced pressure using a rotary evaporator. Aqueous extracts were freeze-dried under vacuum to yield the final crude extracts.

2.3. HPLC-DAD Analysis of Phenolic Compounds

Ethyl acetate, methanol, and aqueous extracts obtained from *I. graveolens* were dissolved in water or alcohol, filtered through 0.20 µm membranes, and analyzed by HPLC-DAD (High-Performance Liquid Chromatography with Diode Array Detection) as described by Küçükaydın et al. (2021). Twenty-six phenolic acid standards were prepared in water and used for profiling. The HPLC-DAD analytical conditions are summarized in Table 1.

3. RESULTS AND DISCUSSION

The phenolic composition of ethyl acetate, methanol, and aqueous extracts obtained from the flowers of *I. graveolens* is presented in Table 2, while the corresponding HPLC chromatograms are shown in Figure 1. Among the 26 phenolic standards tested, 12 compounds were detected in flower extracts. Eleven compounds were identified in the ethyl acetate extract, seven in the methanol extract, and five in the aqueous extract. Luteolin (11.43 mg/g) and coumarin (8.20 mg/g) were determined as the major compounds in the ethyl acetate extract, whereas coumarin was the predominant phenolic in both methanol (21.65 mg/g) and aqueous (11.43 mg/g) extracts.

The phenolic composition of ethyl acetate, methanol, and aqueous extracts from the aerial parts of *I. graveolens* is summarized in Table 3, with representative HPLC chromatograms shown in Figure 2. A total of 12 compounds were detected in aerial part extracts, including 11 in the ethyl acetate extract, seven in the methanol extract, and five in the aqueous extract. Luteolin (14.78 mg/g), quercetin (11.25 mg/g), and trans-cinnamic acid (7.33 mg/g) were identified as the major compounds in the ethyl acetate extract. In contrast, coumarin (18.73 mg/g in methanol; 10.85 mg/g in water) and pyrocatechol (7.38 mg/g in methanol; 6.59 mg/g in water) were the dominant phenolics in the methanol and aqueous extracts, respectively.

The phenolic composition of ethyl acetate, methanol, and aqueous extracts obtained from the roots of *I. graveolens* is provided in Table 4, with HPLC chromatograms shown in Figure 7. Nine compounds were detected in root extracts, including eight in the ethyl acetate extract, six in the methanol extract, and four in the aqueous extract. Luteolin (6.91 mg/g) was the predominant compound in the ethyl acetate extract, whereas rosmarinic acid (5.20 mg/g) and coumarin (4.63 mg/g) were the main constituents in the methanol extract. In aqueous extracts, pyrocatechol (3.47 mg/g) and coumarin (2.69 mg/g) were identified as the major compounds.

4. CONCLUSION

This study provides a comprehensive analysis of the phenolic composition of *Inula graveolens* (L.) Desf. using HPLC-DAD. The results demonstrated that different parts of the plant (flowers, aerial parts, and roots) contain diverse phenolic profiles, with luteolin, coumarin, quercetin, rosmarinic acid, and pyrocatechol identified as the major compounds depending on the extraction solvent. These findings emphasize the solvent-dependent variability in phenolic contents and highlight the importance of optimized extraction techniques for phytochemical studies.

The relatively high levels of luteolin and coumarin, along with other bioactive phenolics, suggest that *I. graveolens* could be a promising natural source of antioxidant and pharmacological agents. This

study contributes valuable insights into the chemical composition of *I. graveolens* and provides a foundation for future research aimed at evaluating its biological activities and potential applications in pharmaceutical, nutraceutical, and cosmetic formulations.

ABSTRACT

Inula graveolens (L), an aromatic medicinal plant belonging to the Asteraceae family, is widely distributed in Europe, Africa, and Asia and is commonly found in the Mediterranean region of Türkiye. This endemic species has long been used in folk medicine for the treatment of respiratory tract infections, coughs, colds, and bronchitis. The present study aimed to evaluate the in vitro antidiabetic potential of flower and aerial part extracts of *I. graveolens* by assessing their inhibitory effects on α -amylase and α -glucosidase enzymes. Plant materials were separated into flowers and aerial parts, dried, powdered, and sequentially extracted with ethyl acetate, methanol, and water. The inhibitory activities of the obtained extracts were determined spectrophotometrically and compared with the standard drug acarbose. At a concentration of 200 (μ g /ml, ethyl acetate extracts of aerial parts and flowers exhibited $52.86 \pm 0.71\%$ and $45.27 \pm 0.23\%$ inhibition against α -amylase, respectively, while acarbose showed $80.56 \pm 0.52\%$ inhibition at the same concentration. Similarly, the highest inhibition against α -glucosidase was recorded for ethyl acetate extracts of flowers and aerial parts, with $70.20 \pm 0.82\%$ and $75.35 \pm 0.86\%$ inhibition, respectively. These values were higher than that of acarbose ($67.30 \pm 0.45\%$), indicating superior activity. Methanol extracts also demonstrated notable activity, with inhibition rates of $61.63 \pm 0.45\%$ and $58.30 \pm 0.62\%$ for flowers and aerial parts, respectively. These findings highlight that ethyl acetate extracts, particularly from the flower and aerial parts, exhibit remarkable α -glucosidase inhibitory activity, surpassing even the standard drug acarbose. The extracts also showed considerable α -amylase inhibition, following a similar trend. Overall, *I. graveolens* demonstrates promising potential as a natural source of antidiabetic agents, warranting further bio-guided isolation studies and mechanistic investigations.

Keywords: *Inula graveolens*, Asteraceae, α -amylase, α -glucosidase, enzyme inhibition, antidiabetic activity

1. INTRODUCTION

The Asteraceae (Composite) family comprises more than 1500 genera and approximately 23,000 species worldwide (Judd et al., 2007). In Türkiye, this family is represented by about 140 genera and nearly 1186 species. The genus *Inula*, a member of the Asteraceae family, is widely distributed in Europe, Africa, and Asia (Lack, 2007) and is especially common in the Mediterranean region of

Türkiye (Ertem, 2023). The genus includes 33 different species, eight of which are endemic to Türkiye, corresponding to an endemism rate of 28.5% (Güner et al., 2012).

Inula graveolens typically grows along roadsides, riverbanks, and arid areas, and is widespread in the Mediterranean region of Türkiye. It is an annual plant that can reach up to 80 cm in height, characterized by sticky, hairy stems and yellow flowers, containing aromatic compounds and essential oils (Afifia et al., 2015). Traditionally, *Inula* species have been used for treating upper respiratory tract infections, coughs, colds, and bronchitis. They are also reported to support the immune system, alleviate acne, and reduce skin inflammations (Oshadi, 2005). Furthermore, their use in treating urinary tract infections, cystitis, nephritis, and uremia has been documented (Kılıç, 2014; Akbulut et al., 2021).

Diabetes mellitus (DM) is a chronic metabolic disorder characterized by hyperglycemia resulting from insulin deficiency or resistance, and its prevalence is increasing globally (Kaveeshwar & Cornwall, 2014; Atkinson et al., 2014; Huang et al., 2016; Yan et al., 2019; Chinsebu, 2019). According to the World Health Organization (WHO, 2020), the number of diabetic patients increased from 108 million in 1980 to 422 million in 2014, with 1.6 million diabetes-related deaths reported in 2016. The International Diabetes Federation (IDF, 2019) estimated that the number of diabetic adults was 463 million in 2019 and is projected to reach 700 million by 2045. Type 1 diabetes is most common in childhood and results from autoimmune destruction of pancreatic β -cells, while type 2 diabetes, representing 90–95% of cases, is characterized by insulin resistance and β -cell dysfunction (Fan, 2017). Current treatments aim at controlling hyperglycemia. Insulin injections are mandatory for type 1 diabetes, while type 2 diabetes is managed through lifestyle modifications and oral antidiabetic agents (Aziz, 2012). Natural plant polyphenols have attracted attention due to their antioxidant properties and ability to inhibit digestive enzymes such as α -amylase and α -glucosidase, thereby delaying intestinal glucose absorption and contributing to glycemic control. Indeed, commonly used antidiabetic drugs such as acarbose and voglibose act via this mechanism (Xu, 2024).

Although several studies have explored the antiproliferative, antioxidant, and enzyme inhibitory activities of different *Inula* species such as *I. viscosa*, *I. britannica*, and *I. discoidea* (Özkan et al., 2019; Khan et al., 2010; Ceylan et al., 2021), little information is available regarding the antidiabetic potential of *I. graveolens*. Therefore, the present study aimed to evaluate the in vitro antidiabetic activity of hexane, ethyl acetate, methanol, and aqueous extracts prepared from the leaves, roots, and flowers of *I. graveolens* by assessing their inhibitory effects on α -amylase and α -glucosidase enzymes

2. MATERIALS AND METHODS

2.1. Plant Material

Inula graveolens (L.) Desf. was collected during its flowering stage in late November 2022 from Kızılağaç, Ula district, Muğla Province, Türkiye. Approximately 2 kg of plant material was harvested. A voucher specimen has been deposited at the Plant Chemistry Laboratory, Department of Chemistry, Muğla Sıtkı Koçman University.

2.2 Extraction

The plant material was separated into roots, aerial parts, and flowers, dried under shade in a cool and ventilated environment, and extracted sequentially with solvents of increasing polarity: hexane, ethyl acetate, methanol, and hot water. After maceration, organic solvents were evaporated under reduced pressure using a rotary evaporator, while aqueous extracts were freeze-dried under vacuum.

2.3. Determination of Antidiabetic Activity

Hexane, ethyl acetate, methanol, and aqueous extracts were dissolved in dimethyl sulfoxide (DMSO) or distilled water, depending on their solubility, and subjected to in vitro α -amylase and α -glucosidase inhibitory assays as described below

2.3.1. α -Amylase Inhibition Assay

The α -amylase inhibitory activity of the extracts was determined following the method of Quan et al. (2019), with slight modifications. The reaction mixture consisted of 25 μ L of extract solution at different concentrations and 50 μ L of α -amylase solution (0.1 U/mL in 20 mM phosphate buffer, pH 6.9, containing 6 mM NaCl). After pre-incubation at 37 °C for 10 min, 50 μ L of 0.05% starch solution was added and incubated for another 10 min. The reaction was stopped by adding 25 μ L of 0.1 M HCl and 100 μ L of iodine solution. Absorbance was measured at 565 nm.

2.3.2. α -Glucosidase Inhibition Assay

The α -glucosidase inhibitory activity was determined according to the method of Kim et al. (2000), with modifications. The assay mixture contained 50 μ L of 0.01 M phosphate buffer (pH 6.9), 25 μ L of 0.5 mM p-nitrophenyl- α -D-glucopyranoside (PNPG), 10 μ L of extract solution, and 25 μ L of α -glucosidase (0.1 U/mL in 0.01 M phosphate buffer, pH 6.0). After incubation at 37 °C for 20 min, the reaction was terminated by adding 90 μ L of 0.1 M sodium carbonate. The release of p-nitrophenol was measured at 400 nm..

3.RESULTS AND DISCUSSION

The α -amylase inhibitory activities of the extracts are presented in Table 1. As shown in the table, the ethyl acetate extract of the aerial parts of *I. graveolens* exhibited the highest activity, with an inhibition value of $52.86 \pm 0.71\%$ at a concentration of 200 μ g/mL, followed by the ethyl acetate extract of flowers with $45.27 \pm 0.23\%$ inhibition. Compared to the reference compound acarbose, the extracts displayed lower α -amylase inhibitory activity overall. Nevertheless, the inhibition values of both aerial and flower ethyl acetate extracts at 200 μ g/mL were comparable to that of acarbose at 25 μ g/mL, suggesting that these two extracts may possess promising activity.

The α -glucosidase inhibitory activities of the extracts are shown in Table 2. Among the tested samples, the ethyl acetate extracts of flowers and aerial parts exhibited the highest inhibition against α -glucosidase, with activities comparable to the standard drug acarbose. At a concentration of 200 μ g/mL, the aerial and flower ethyl acetate extracts demonstrated inhibition rates of $75.35 \pm 0.86\%$ and $70.20 \pm 0.82\%$, respectively, while acarbose showed $78.26 \pm 0.35\%$ inhibition at the same concentration. Following these, methanol extracts of flowers and aerial parts exhibited considerable activity, with inhibition rates of $61.63 \pm 0.45\%$ and $58.30 \pm 0.62\%$, respectively. In line with the α -amylase inhibition results, the root extracts showed the lowest inhibitory activity against α -glucosidase.

Table 1. α -Amylase inhibitory activities of *Inula graveolens* extracts (% inhibition)

Extracts/Standard	25 $\mu\text{g/mL}$	50 $\mu\text{g/mL}$	100 $\mu\text{g/mL}$	200 $\mu\text{g/mL}$

4.CONCLUSION

This study demonstrated that ethyl acetate extracts of the flowers and aerial parts of *Inula graveolens* exhibited the strongest α -glucosidase inhibitory activity, surpassing even the standard drug acarbose at certain concentrations. Methanol extracts also showed considerable inhibitory effects, while root extracts were the least active. Parallel trends were observed in α -amylase inhibition. Overall, these findings indicate that *I. graveolens* may serve as a promising natural source of antidiabetic agents. Further bioassay-guided studies and mechanistic investigations are required to isolate active compounds and evaluate their pharmacological potential.

KNOWLEDGE ABOUT THE GENETICAL, MORPHOLOGICAL AND PHENOLOGICAL DIVERSITY OF THREE LINDEN SPECIES (*TILIA CORDATA* MILL., *TILIA PLATYPHYLLOS* SCOP. AND *TILIA TOMENTOSA* MOENCH.) IN BOSNIA AND HERZEGOVINA AND POTENTIAL FOR BETTER MANAGEMENT OF LINDEN FORESTS

ABSTRACT

The paper presents an analysis of the first report on molecular studies of the *Tilia* genus complex in Bosnia and Herzegovina, with brief information on some measured morphological parameters of leaves in lindens in Bosnia and Herzegovina. Based on the literature search process on the genetic diversity of the species *T. cordata* Mill., *T. platyphyllos* Scop. and *T. tomentosa* Moench., it was noted that genetic studies had not been conducted before 2020. As part of the study of the genetic diversity of the three dominant linden species from Bosnia and Herzegovina, a significant level of diversity was discovered. However, it seems that the full results of the research have not been published and that only some partial results have been published, and that on the website of the research sponsor, which is the *German Federal Environmental Foundation*. It is worth noting that the research focuses on the species *T. tomentosa*, which has been identified as the "tree of the future". Resistance to high droughts and lack of moisture in the soil makes the silver-leaved linden very valuable for establishing commercial plantations in the future, but also important for the survival of beneficial insect species and strengthening overall biodiversity. This tree can significantly help improve the climate of cities and municipalities where linden trees are planted, as they provide shade and protection from harmful ultraviolet rays for human health. Since climate change significantly threatens to disrupt the balance of everyday life, wood markets and local economic conditions, further research into the benefits of linden trees is very necessary for the forestry industry and for the general good of the bosnian-herzegovinian community. To this end, it is of great importance to present to the public that there is molecular research on the genus *Tilia* in Bosnia and Herzegovina and that it indicates that linden can be used for various purposes, as well as that it has a prosperous future in planting.

Keywords: *Tilia cordata*, *Tilia platyphyllos*, *Tilia tomentosa*, lime forests, Bosnia and Herzegovina, lime morphology, lime genetics

INTRODUCTION

At the beginning of research on the genus *Tilia* in Bosnia and Herzegovina, it was realized that no molecular studies had been conducted until 2020. The main reason for this is that either there was not enough interest in researching lindens, as they were mainly used as trees for establishing alleys and parks, or there were no funds available to conduct any genetic research at

¹ International Burch University, *Department of Management*, PhD candidate, email: selma.vezagic@stu.ibu.edu.ba

that level. According to an **Oral statement by Ballian (2016)**, the main reason for the lack of research on lindens is that they are very complicated for molecular analysis.

According to the **Oral Statement of Sejdić (2020)**, the then director of the *Public Enterprise “Bosanskohercegovačke šume”* in Sarajevo, there were several linden research plots in the Konjic Municipality in Bosnia and Herzegovina, where exclusively phenological observations were conducted in the context of fruiting of trees and potential for honey production and beekeeping. According to **Vejzagić & Omerbegović-Arapović (2025)**, linden trees are very important for considering the establishment of mass commercial plantations, because they can help maintain honey production and help the sustainability of insect populations in forests. The authors state that the exceptional benefits of linden have been proven in the production of not only honey, but also wood pulp, medical preparations, but also cosmetics, all of which have their own significant place in the market for products derived from wood pulp, or forestry.

According to **DBU.de (2021)**, *T. cordata* trees are very difficult to distinguish from *T. platyphyllos* trees in the field, making it difficult to confirm which species they are without molecular identification. The report states that *T. platyphyllos* had to adapt morphologically to new climatic conditions, starting as early as 9,000 years ago. Namely, since the climate has changed significantly in the Scandinavian countries in the past, there has been a significant drop in temperatures in the natural habitats of *T. cordata* and *T. platyphyllos*. With the average temperature falling below 15 degrees Celsius, it has become very difficult for *T. platyphyllos* seeds to germinate. Therefore, the fragmentation of the habitats of *T. cordata* and *T. platyphyllos* began due to climatic factors, and/or species such as *T. platyphyllos* and *T. tomentosa* began to seek their last refuges in more southern habitats, heading towards the very coasts of the Balkan Peninsula (*T. tomentosa*).

The results of research on several forest tree species in Bosnia and Herzegovina and the surrounding countries have shown that, depending on the type of climate, altitude, exposure and vegetation type, there is a significant morphological diversity of species (**Ballian et al., 2017, Franjić, 1994, Kvesić, 2019, Hajrudinović-Bogunić, 2023**). This has been written about by prominent forestry experts and authors of the most important forestry university textbooks in Bosnia and Herzegovina and the surrounding area as part of the description of morphological characteristics and habitat conditions (**Mekić, 1998**).

The aim of this review is to comment on the main results of molecular and scarce morphological research conducted by a researcher on three linden species in Bosnia and Herzegovina, *T. cordata* Mill., *T. platyphyllos* Scop. and *T. tomentosa* Moench., within the framework of the “MOE-Scholarships” scholarship program in Germany. The Report (**DBU.de, 2021**) notes that the research was carried out in two German institutes dealing with *Forest Genetics*. The research is very interesting from the genetics aspect, especially because it provides information that in Bosnia and Herzegovina, in certain locations, there are trees that have started to develop different fruits, and the discovery was published in the *Forestry Journal of the Faculty*

of Forestry, University of Banja Luka, Bosnia and Herzegovina (Vejzagić, 2022). In the following, comments will be presented on all described results about lindens.

MATERIAL AND METHOD

This review article contains information on the morphological and molecular results of the first comprehensive study of the three dominant linden species in Bosnia and Herzegovina: *T. cordata* Mill., *T. platyphyllos* Scop. and *T. tomentosa* Moench. The report with the results of the study was published on the official website of the *German Federal Environmental Foundation* in 2021, and is written in German. A literature review on the scientific review conducted revealed that no previous articles with a complete overview of molecular and morphological results have been published on this study in any journal. Therefore, one of the goals of this review article is to point out the importance of publishing the overall molecular and morphological results in a genetic journal. In order to obtain additional information about what scientific research on lime trees in Bosnia and Herzegovina has been conducted in addition to this, the following key terms were used in a Google search: 1) *Tilia in Bosnia and Herzegovina*, 2) *Tilia cordata in Bosnia and Herzegovina*, 3) *Tilia platyphyllos in Bosnia and Herzegovina*, 4) *Tilia tomentosa in Bosnia and Herzegovina*, 5) *lime forests in Bosnia and Herzegovina*, 6) *Bosnian lime morphology* and 7) *Bosnian lime genetics*.

This review article used a meta-analysis of the available: 1. Scientific research report entitled **DBU.de (2021)**: "Morphological, phenological and genetic characteristics of linden stand structures (*Tilia cordata* Mill., *Tilia platyphyllos* Scop. and *Tilia tomentosa*)", as well as 2. The following three peer-reviewed papers deal with morphological and/or phenological research on the three main linden species in Bosnia and Herzegovina, as follows: a) **Tomić et al. (2014)**: "FENOLOGIJA CVJETANJA TRI VRSTE LIPE (*Tilia* sp.) NA PODRUČJU GRADA BANJA LUKE" (engl.: *FLOWERING PHENOLOGY OF THREE SPECIES OF LINDEN (Tilia sp.) IN THE AREA OF THE CITY OF BANJA LUKE*), b) **Vejzagić et al. (2021)**: "Preliminary research of morphological traits of silver linden (*Tilia tomentosa* Moench.) leaves in Bosnia and Herzegovina and Serbia", and c) **Vejzagić, S. (2022)**: "On the discovery of the multibracteate silver-leaved linden (*Tilia tomentosa* Moench.) IZ MOSTAR, BOSNIA AND HERZEGOVINA".

In accordance with the available research material, the analysis and discussion of the results is planned in the following three *sub*-chapters: 1) Molecular investigations of the *Tilia* complex in Bosnia and Herzegovina, 2) Morphological analysis of *T. cordata* Mill., *T. platyphyllos* Scop. and *T. tomentosa* Moench. from Bosnia and Herzegovina, i 3) Other relevant investigations within the *Tilia* complex in Bosnia and Herzegovina.

RESULTS AND DISCUSSION

The results of the meta-analysis will be presented in the following three brief sub-chapters, with help of tables (for better clarity). The first *sub*-chapter consists of the main part

of the text, because the given (analysed) report on molecular results in *Tilia* is much more abundant with molecular results. The second *sub*-chapter is similar but shorter, because it consists of the very brief results on a few morphometric parameters and findings of the

morphological analysis of the leaves in *T. tomentosa* in separate research (Vejzagić et al., 2021). The third sub-chapter consist almost no results about the phenology findings in *Tilia* in scope of German institutes conducted research (DBU.de, 2021), but it focuses more on the phenological results of Tomić et al. (2014) and it mentions discovery of a multibracteal linden fruit in Mostar, Bosnia and Herzegovina. The reason why mentioning this discovery was planned in a third and not in second sub-chapter is to avoid mentioning it twice, and to emphasize the importance of conducting phenological research in the future, by seeking for additional data about existence of the multibracteal fruit in other locations.

Molecular investigations of the *Tilia* complex in Bosnia and Herzegovina

This sub-section reviews the most important information from the DBU report on molecular research of the *Tilia* complex in Bosnia and Herzegovina. A literature review has established that the report published in 2021 is the first of its kind to address the molecular characterization of linden in that country.

According to the DBU.de (2021), a complex study of the three dominant linden species in Bosnia and Herzegovina was carried out due to the great ecological importance of *Tilia cordata* Mill. (abbreviated as *T. cordata*), *Tilia platyphyllos* Scop. (abbreviated as *T. platyphyllos*) and *Tilia tomentosa* Moench. (abbreviated as *T. tomentosa*) and due to the fact that the genetic and morphological variability of these species attracts great interest from the scientific community. The linden is a tree that is becoming increasingly important in the context of climate change, as it is believed to have the ability to adapt to dry habitats. Therefore, the research focused on molecular analysis but also typification from the aspect of the climate type prevailing in the habitats in which the linden trees were sampled, then from the aspect of altitude, soil type, ecological type of vegetation and tree exposure. One of the goals of the research was to identify potential linden hybrids in nature, possibly new varieties, breeds, etc. (DBU.de, 2021).

The study included a total of 317 trees morphologically identified as *T. cordata*, *T. platyphyllos* and *T. tomentosa*, from several locations in Bosnia and Herzegovina: 1) Kladanj, 2) Srebrenik, 3) Čajniče, 4) Bosanski Petrovac, 5) Kakanj, 6) Sarajevo, 7) Tešanj, 8) Bosansko Grahovo, 9) Livno, 10) Posušje, 11) Mostar, 12) Tomislavgrad and 13) Tomislavgrad Kovač. The study relied on data from the author Herman (1971), who described where linden trees grow and how to identify them in the field. The report states that, in addition to populations, so-called meta-populations were formed in the research, in order to cover as much of the territory of Bosnia and Herzegovina as possible (a map of locations is provided), and describes that meta-populations are those that include linden trees from different habitats, which are nevertheless similar in terms of ecological and biological growth conditions.

Image 1. Map of the locations of sampled linden trees according to the reviewed report.

The report states that three populations from Germany were taken as *Control* populations, but we decided not to list them, because we want to focus on the molecular results of trees exclusively from Bosnia and Herzegovina. It is important to note that the researcher used *DNA* that he extracted from leaves, twigs (wood) and buds of small-leaved (*T. cordata*), large-leaved (*T. platyphyllos*) and silver-leaved (*T. tomentosa*) linden, which he morphologically identified in the field, and then established their species affiliation using *DNA* analysis.

The importance of the first molecular study for understanding the *Tilia* complex in Bosnia and Herzegovina is best demonstrated by the fact that it is one of the few studies conducted in Europe after the study by **Phuekvilai & Wolff (2013)**, who worked on the characterization of microsatellite loci in *T. platyphyllos* trees and on cross-amplification in related species. They then used a set of 15 microsatellite markers, in which most loci showed a high degree of polymorphism in two populations of *T. platyphyllos*. The results of cross-amplification showed that as many as 12 of the 15 loci were amplified polymorphically in as many as 23 linden species. The research conducted as part of the MOE-Scholarship is also useful from the aspect of saving chemicals, because it was found that in the analysis of a large number of *T. cordata*, *T. platyphyllos* and *T. tomentosa* trees from Bosnia and Herzegovina, the *Tc918* marker (locus) only functions in *T. platyphyllos*.

Table 1. Overview of molecular results of genetic analyzes of three linden species (*T. cordata* Mill., *T. platyphyllos* Scop. and *T. tomentosa* Moench.) in Bosnia and Herzegovina (DBU.de, 2021)

Research method and focus	Overview of the most important molecular results
The CTAB protocol was used to extract DNA from	Results from microsatellite analysis showed that the <i>Tc918</i> locus was functional only in <i>T. platyphyllos</i> . It was therefore omitted
buds, leaves and twigs (wood) of three linden species, which were initially identified as small-leaved (<i>T. cordata</i>), large-leaved (<i>T. platyphyllos</i>) and silver-leaved (<i>T. tomentosa</i>) linden based on macroscopic characteristics in the field. Trees were sampled from 13 (meta)populations from all over Bosnia and Herzegovina, trying to cover as many different habitats as possible, which are characterized by different climatic characteristics, vegetation type, altitude, exposure, slope, as well as the type of soil on which the trees grow. The DNA content was measured randomly with a photometer and diluted to approximately 20 ng/μl. The report states that this solution was subsequently available for PCR reactions, using the Qiagen multiplex kit. The study was conducted using a set of 12 nuclear microsatellite loci (<i>Tc5</i>, <i>Tc31</i>, <i>Tc6</i>, <i>Tc7</i>, <i>Tc4</i>, <i>Tc8</i>, <i>Tc915</i>, <i>Tc963</i>, <i>Tc951</i>, <i>Tc918</i>, <i>Tc920</i>, <i>Tc11</i>), according to the method of Phuekvilai & Wolff (2013)	from the calculations of genetic differences between species and locations. The remaining 11 out of 12 microsatellites were used to characterize populations and identify species and potential hybrids. The application of microsatellite on <i>T. tomentosa</i> samples showed that some populations are clearly separated or isolated from others, as is the case with the population from the Srebrenik site. Molecular analyses indicate that the <i>T. tomentosa</i> population from Mostar, which grows in a thermophilic habitat, is genetically more similar, or even coincides with a group of <i>T. tomentosa</i> populations growing in northwestern Bosnia, in continental and mesophilic conditions. Although it was expected that the mesophilic populations of <i>T. tomentosa</i> from northwestern Bosnia would have a stronger genetic influence on the continental populations of <i>T. tomentosa</i> from northeastern Bosnia (the Srebrenik and Kladanj sites), this was not the case. The analyses also showed that the existence of potential hybrids resulting from crossing <i>T. tomentosa</i>, as well as the occurrence of genetically identical trees, is present. The occurrence of clonal reproduction is part of the question of what are the main reasons for the occurrence of a large number of genetically identical trees. The need for more detailed analyses was indicated by the fact that a certain number of trees identified as <i>T. cordata</i> (based on morphological characteristics) turned out to be <i>T. platyphyllos</i> (after performing genetic analysis identification), and that a certain number of trees identified as <i>T. platyphyllos</i> (also based on morphological characteristics) turned out to be <i>T. tomentosa</i>. Deeper analyses are particularly important because trees identified as <i>T. tomentosa</i> were also observed, which have morphological characteristics of the fruits of all three dominant linden species in Bosnia and Herzegovina (<i>T. cordata</i>, <i>T.</i>

and using 6 <i>cpDNA</i> microsatellites (<i>ccmp3</i>, <i>ccmp4</i>, <i>ccmp5</i>, <i>ccmp6</i>, <i>ccmp10</i> and <i>μkk3</i>), according to the method of	<i>platyphyllos</i> and <i>T. tomentosa</i>). The results of the genetic analysis of three linden species from Bosnia and Herzegovina show the existence of clearly separated clusters of <i>T. cordata</i>. Certain populations are, however, very similar and form a common cluster. The researcher concludes that there are clear boundaries that prevent populations from networking through gene flow. The researcher compares populations from Bosansko Grahovo and Livno, where it is observed that the peripheral trees of the populations are very close to each other. Comparing the population from Tomislavgrad with the population from Čajniče, it is observed that the two populations are genetically distinct
Weising & Gardner, 1998. The report states that the research fellow conducted the analyses at the Institute for Applied Forest Genetics “AWG” in Bavaria, Germany, and at the Forestry Institute “FVA-BW” in Germany. The researcher focused on determining the tree species involved and the <i>intra</i>- and <i>inter</i>-population variability of the populations. The analytical programs <i>Software Structure 2.2</i> (according to Pritchard et al., 2000) and <i>Software Genalex</i> and <i>Alrequin</i> were used for the genetic analyses.	The results of the analysis obtained using the <i>STRUCTURE</i> software have allegedly changed the initial picture of the Kladanj population. According to the initial morphological identification, the trees sampled in Kladanj were <i>T. tomentosa</i>, however, genetic analysis determined that they were <i>T. cordata</i> and <i>T. platyphyllos</i> trees. The final considerations of the report on the genetic results obtained on the <i>Tilia</i> complex in Bosnia and Herzegovina state that <i>T. tomentosa</i> is an important species for understanding the process of fragmentation of lime forests in Southeast Europe and the process of climate change in the context of forest macroclimate. This makes the study of lime significant from the perspective of bioclimatology, climatology, ecology, dendrology and genetics, because it demonstrates how these different scientific disciplines can synergistically explain the overall picture of the evolutionary development of <i>T. cordata</i>, <i>T. platyphyllos</i> and <i>T. tomentosa</i>.

Lobo et al. (2018) studied the local adaptation of highly fragmented populations of *T. cordata* and found that populations with a high degree of genetic variation have the ability to respond to selection based on their high degree of heritability. This ultimately indicates the existence of adaptive potential, or plasticity, which allows species to adapt. However, the researchers did not rule out the influence of epigenetics on the creation of local adaptation. It is noted that the research conducted by **Lobo et al. (2018)** is interesting for linden research in Bosnia and Herzegovina, since the report puts them in the focus of trees of the future, especially from the aspect of adaptation to climate change.

The **DBU.de (2021)** report indicates that there are populations that are isolated from the rest, and that there are populations that share similarities with geographically distant populations. This is the case with the population from Srebrenik (*T. tomentosa*), which does not have much

similarity with the population from Mostar (*T. tomentosa*), but the population from Mostar is more closely related to the population from Bosanski Petrovac (*T. tomentosa* and other lime species). Research conducted by **Logan et al. (2015)** in the United Kingdom indicates the existence of distinct but also shared gene pools. In order to determine the detailed differences in the genetic structure of populations from Bosnia and Herzegovina, it is necessary to publish the results of the overall research project in the future.

Morphological analysis of *T. cordata* Mill., *T. platyphyllos* Scop. and *T. tomentosa* Moench. from Bosnia and Herzegovina

In addition to genetic analysis, the study included morphological analysis of 6340 leaves and 12640 linden fruits.

Table 2. Overview of the results of morphological analyzes of three linden species (*T. cordata* Mill., *T. platyphyllos* Scop. and *T. tomentosa* Moench.) in Bosnia and Herzegovina (**DBU.de, 2021**)

Research method and focus	Overview of the most important morphological results
In morphological analyses of measured parameters of leaves and fruits, a modified standard method for morphological measurements of forest species in the Balkan region was used, created by Prof. Dr. Franjic, from the <i>Faculty of Forestry, University of Zagreb</i>. The methodology for measuring linden fruits was considered because in Bosnia and Herzegovina, silver-leaved linden (<i>T. tomentosa</i>) fruits with more than one wing (<i>bracteum</i>), i.e. fruits with primary, secondary and tertiary rows of bracts, occur. The following parameters were measured in leaves: 1) <i>leaf length</i>, 2) <i>leaf width</i>, 3) <i>central nerve length</i>, 4) <i>angle of intersection of the first developed right nerve with the leaf base</i>, 5)	The results of morphological measurements are given very sparsely, and only a few obtained values are stated. The report states that as part of the measurement of morphological parameters of linden in Bosnia and Herzegovina, the longest leaf petiole was measured in <i>T. tomentosa</i>, and that in Mostar. The Mostar population of silver-leaved linden is characterized by thermophilic vegetation and the presence of a <i>sub-Mediterranean</i> climate. The average petiole length for the entire population is 32.21 mm. As for the shortest leaf petiole measured, it was measured in the linden metapopulation sampled in the area of Tomislavgrad and Čapljina. The average length of the leaf

peduncle length, 6) number of teeth on each 1 cm of length, 7) type of hairiness and 8) type of serration. The following traits were measured in fruits: 1) peduncle length, 2) length of primary, secondary, and tertiary wings, 3) length of the base of primary wings, 4) separation position, 5) seed width, 6) seed length, and number of ridges.	petiole was measured for the entire metapopulation and is 23.12 mm. At the end of presenting these results, the researcher states that the morphological measurement patterns created based on morphological measurement methods in Croatia and Bosnia and Herzegovina yielded mostly expected results (patterns of morphological forms and characteristic leaf dimensions in individual climatic regions).

From the available data of the **DBU.de (2021)** report, it is observed that only two results for the average leaf petiole length are specifically stated, namely for the population from Mostar and the meta-population *Tomislavgrad-Kovac*. In the population from Mostar, the average leaf petiole length for the entire population was recorded as 32.21 mm, while for the metapopulation that is represented with the average value of 23.12 mm. Accordingly, the average leaf petiole length is as much as 28.22 % shorter in the *Tomislavgrad-Kovac* metapopulation compared to the population from Mostar.

When reviewing the results of the morphological analysis of *T. tomentosa* trees in Bosnia and Herzegovina, conducted by **Vejzagić et al., (2021)**, the results of several morphological parameters of leaves are observed compared to the *DBU* report. The study measured the morphological properties of silver-leaved linden leaves from the Sana River Valley (two locations) and from the Neretva River Canyon (two locations). As Control populations, the researchers took two populations from two locations in the Republic of Serbia, but we will not describe them in detail here because we want to focus on domestic / bosnian-herzegovinian populations. The researchers sampled 30 trees per location and 30 leaves per individual tree.

The results obtained by morphological measurements are: 1) The average value of the length of the petiole for all populations, which is 40.3 mm, 2) The average length of the leaf, which is 111.0 mm, 3) The average width of the leaf, which is 90.7 mm, 4) The average distance of the first right developed vein from the base of the leaf, which is 0.3 mm, 5) The average angle of the first right developed vein that closes with the central vein, which is 47°7', 6) Average length of the central vein, which is 90.4 mm, 7) Average *length/width* ratio of the blade, which is 1.3, 8) Average *width/length* ratio of the blade, which is 0.8, 9) Average total length of the central blade with petiole, which is 130.7 mm, 10) Average length midrib *versus* petiole length, which is 2.5, 11) The average length of the petiole / the total length of the central vein and the petiole, which is 0.3, as well as 13) The number of primary teeth *per* 1 centimeter of the length of the leaf edge (the largest number of individuals had two primary teeth *per* 1 cm of the length of the leaf edge).

Analysis of variance for leaf morphological properties indicates the existence of statistically significant differences for all measured leaf properties by population, while Duncan's test showed the separation of all populations into separate groups for the majority of measured properties. Therefore, from the data that can be compared, it is visible that in the **DBU.de (2021)** research the average length of the leaf petiole of all measured trees reached 32.21 mm (population in Mostar), while for all the measured populations in the research of **Vejzagić et al. (2021)** this value was 40.30 mm (what is about 25.1% more compared to the average leaf petiole length from the *DBU* report).

Although according to the **DBU.de (2021)** study, the Mostar population consists of *T. tomentosa* trees, it is observed that the trees sampled in the **Vejzagić et al. (2021)** study differ significantly in leaf petiole length, so that trees in the Sana River canyon do not reach a length of 40 mm at all, while trees from the Neretva River canyon exceed a petiole length of more than 40 mm. The discussion leads to the logical question of whether climatic oscillations and the time of sampling of plant material significantly influenced the length of the petiole in the year of plant material collection, and whether significant differences in leaf petiole length, observed on herzegovinan (southern) locations, differ on the local level. For sure that should certainly be investigated in future studies of linden in Bosnia and Herzegovina, especially in locations with linden in the Neretva River canyon.

Other relevant investigations within the *Tilia* complex in Bosnia and Herzegovina

Among other significant research conducted on linden trees in Bosnia and Herzegovina, an article published in the *Forestry Journal* of the *Faculty of Forestry* in Banja Luka stands out, where the authors **Tomić et al. (2014)** published the results of a phenological study of three linden tree species in the city of Banja Luka: *Tilia cordata* Mill., *Tilia platyphyllos* Scop. and *Tilia argentea* (which is one of the synonyms of *T. tomentosa* Moench. in Bosnia and Herzegovina. The authors researched the phenological flowering phases on 27 sampled trees of three species of linden, namely at the locations *Park Mladen Stojanovic*, *University Campus* and *Starcevica*. The authors defined five phases of flowering that they followed, namely: 1) Appearance of the first flowers, 2) Beginning of full flowering (when about 25 % is open flowers), 3) The time of full flowering (when most of the flowers are open, on more than 50% of the inflorescence), 4) The end of full flowering (when about 75% of the flowers do not have a flower sheath or perianth) and 5) The end of flowering (when all flowers remain without a perianth).

According to the results of the research, the first flowers at the *Park Mladen Stojanovic* site appeared on 27.05. for *T. platyphyllos*, and for *T. cordata* on 10.06. The species *T. argentea* began to bloom later, on 16.06. The first flowers at the *University Campus* site appeared on 28.05. for *T. platyphyllos* and on 10.06. for *T. cordata*. The species *T. argentea* began to bloom the latest, on 15.06. At the *Starcevica* site, *T. platyphyllos* bloomed first, on 26.05., while *T. cordata* began to bloom on 09.06. The species *T. argentea* was the last to bloom, on 17.06. As

for the last phenological phase that was observed, which is the *End of flowering*, at the *Park Mladen Stojanovic* location, the leaves of *T. platyphyllos* fell first. On the same day, the *End of flowering* of *T. platyphyllos* was spotted at the *University Campus* location, and two days earlier, on 11.06., the *End of flowering* for *T. platyphyllos* was observed at the *Starcevic* location. On 23.06., the *End of flowering* of *T. cordata* was observed at the *University Campus* and *Starcevic* locations, while at the *Park Mladen Stojanovic* location, the *End of flowering* was observed on 24.06. For the species *T. argentea*, the *End of flowering* occurred on a) 27.06. at the *University Campus* location, b) 28.06. at the *Park Mladen Stojanovic* location, and c) 29.06. at the *Starcevic* location. (Tomić et al., 2014)

The authors state that one *T. cordata* tree at the *Starcevic* site had a flowering period that was 6 days shorter than other trees. The authors assume that the reason for the shorter flowering period of *T. argentea* and *T. cordata*, compared to *T. platyphyllos* (which flowers somewhat longer), is dependent on the value of average daily temperatures. The authors also state an interesting fact, that a greater change in the value of relative air humidity for the flowering period of *T. platyphyllos* was probably observed with a longer duration of its individual flowering phases, and this was the case at all investigated sites. (Tomić et al., 2014)

The phenological, morphological and genetic characteristics of linden depend on numerous factors, such as growing conditions, climate, weather fluctuations, other plant species in the community, slope, altitude, etc. The authors Logan et al. (2019) studied the genetic diversity and reproductive characteristics of linden and concluded that leading-edge populations have reduced genetic diversity and reduced reproductive output, which, according to the authors, may limit their potential to successfully rank in expansion under the influence of climate change. De Jaegere et al. (2016) reviewed the ecological, physiological and silvicultural characteristics of small-leaved (*T. cordata*) linden and came to results that indicate a broader context of high resilience to drought and suitability for mixed forest management in terms of different possible climate change scenarios. Certainly, there will be an idea of thinking about the phenology of flowering and leaves of linden trees in the future in terms of climate change. Ruņģis & Krivmane (2021) investigated the genetic diversity and population structure of *T. cordata* in Latvia and found that there is a relatively high level of genetic variation but weak population differentiation, indicating good potential for conservation and sustainable forest management. There are several other significant studies that indicate the importance of genetic diversity in linden and how it can later be used for sustainable forest management in the context of climate change. It is worth noting that the authors Wolff et al. (2021) studied *T. cordata* and *T. platyphyllos* from the Bavarian Forest National Park and concluded that both linden species are characterized by sufficient genetic diversity for conservation. It is believed that careful management can achieve the planting of *non*-native species in the future, and that guided restoration efforts must be resorted to in order to preserve the balance and ecological differences between species. Heinrichs et al. (2021) studied the impact of *T. tomentosa* on plant diversity in elevational transects in western Romania and concluded that the dominance of *T. tomentosa* may

have an impact on reducing understorey diversity. Therefore, it was observed that *T. tomentosa* provides potential for transitional habitats under the influence of climate change and supports shade-tolerant species. If this research were to be brought into the context of morphological and phenological studies, it is likely that patterns of phenological parameter measurements could be found in such forests, because the dominance of *T. tomentosa* may also raise the question of whether leaves and flowers are better developed and whether the species generally has the conditions for the development of larger vegetative organs as well as possibly better conditions for leafing, flowering and fructification.

From the numerous listed studies on lindens and those that included lindens in their scope of research, it is noticeable that lindens are very interesting to study, especially from the perspective of genetics. Lindens are greatly underestimated and insufficiently researched, as evidenced by the research of **Zhelev et al. (2020)**, who studied the taxonomic diversity and genetic resources of *Tilia* species, and emphasized that it is necessary to pay attention to lindens, to document the existing conservation genetic variation, in order to contribute to raising awareness of the genus *Tilia* in terms of forest management and supporting the resilience of forest tree species under the influence of climate change. That the study of morphological and genetic research on lindens in the context of the future of sustainable forest management in Europe is also important for Bosnia and Herzegovina, wrote **Vežagić et al. (2021)**, but also the **DBU.de (2021)** report, which places *T. tomentosa* and linden in general at the very top of the list of "trees of the future" that could save forest biodiversity, the survival of bees and other insects (**Vežagić & Omerbegović-Arapović, 2025**), but also save the market for forest wood assortments at least at the local level (production of furniture, small construction equipment, etc.).

Potentials in research are seen in additional research on a new type of fruit in *T. tomentosa* in Mostar (**Vežagić, 2022**), which is characterized by rows of primary, secondary, and tertiary bracts on the fruit, which the author believes can help in further dispersal of the fruit and seeds by wind, which could help in the spread of the species to further habitats. Further potentials, for research at the molecular level, are also seen in clarifying the occurrence of clonal trees in natural habitats and studying potential apomixis. The **DBU.de (2021)** report points to these potentials of molecular research, and recommends continuing work in the field of genetic diversity of trees of the genus *Tilia* in Bosnia and Herzegovina.

CONCLUSION

This review article has reached the most significant conclusions about linden trees from Bosnia and Herzegovina, which are:

1. Within the *Tilia* complex in Bosnia and Herzegovina, there are significant genetic differences between (*interpopulation* variability) linden populations but also within (*intrapopulation* variability) the same species, as is the case with populations composed of *Tilia tomentosa* trees.

2. Morphological measurements of trees of three linden species from Bosnia and Herzegovina (*T. cordata* Mill., *T. platyphyllos* Scop. and *T. tomentosa* Meonch.) show that the length of the leaf petiole differs significantly among populations, suggesting a significant influence of local ecological factors and microclimatic conditions.
3. A study of phenological parameters in the city of Banja Luka in Bosnia and Herzegovina showed that phenological differences in flowering between species and locations confirm that average daily temperatures and relative humidity affect the length and onset of flowering, and that they should be given full attention in future phenological studies.
4. The report of the MOE-Scholarship Program, **DBU.de (2021)**, and the research of **Vejzagić et al. (2021)** consistently point to the importance of molecular analyses in understanding the population structure of linden, since trees with interesting morphological characteristics provide an excellent basis for genetic research.
5. Molecular differences between the Herzegovinian and Krajina populations in Bosnia and Herzegovina, especially Mostar and Bosanski Petrovac, suggest a complex history of the spread and isolation of linden species in the country, which is why it would be interesting to follow the "Gene Flow" of linden in Bosnia and Herzegovina and the countries of the Region, and to name genotypes and haplogroups.
6. The presence of specific fruit shapes in *T. tomentosa* in Mostar represents an interesting potential for future research into the dispersal of silver-leaved lime seeds in nature, and especially for investigating the evolutionary adaptation of this species. This phenomenon should also be investigated in the countries of the Region.
7. Research on clonal trees and the possibility of apomixis may open new questions about the reproductive biology of linden under natural conditions in Bosnia and Herzegovina, and it is necessary to devise a way to finance molecular research on *Tilia* in the country in the future.
8. Phenological studies (**Tomić et al., 2014**) indicate that *T. platyphyllos* has the longest flowering period, while *T. cordata* and *T. tomentosa* show shortened phenophases under certain climatic conditions, which shows the special potential of large-leaved linden in the future from the aspect of insect pollination and importance for insect biodiversity.
9. The observed statistically significant morphological differences between populations emphasize the need to preserve local linden genotypes in Bosnia and Herzegovina in future planning of sustainable management of forest ecosystems.
1. Linden is confirmed as the "tree of the future" for climate-adapted forests in Bosnia and Herzegovina, with important roles in biodiversity conservation, as well as in the context of pollinating insects and in the maintenance of the local timber industry and sustainable planning of forest plantations.

Acknowledgements: This paper is the result of nine years of research on linden in Bosnia and Herzegovina and the Region and is planned as a basis for the theoretical part of the doctoral thesis at the *International Burch University* in Sarajevo. Due to the impossibility of publishing the overall molecular results (**DBU.de report, 2021**), this paper is the only opportunity to show the

public the richness of the *Tilia* “Gene Pool” in Bosnia and Herzegovina and to introduce the academic community and Bosnian-Herzegovinian society to linden in Bosnia and Herzegovina as a potential solution to climate change at the local (state) level.

Special thanks to the laboratory supervisors at the Institute for Applied Forest Genetics AWG, in Teisendorf, Dr. Barbara Fussi, and at the FVA-BW Institute in Freiburg, Dr. Aikaterini Dounavi. Special thanks also go to Prof. Dr Dalibor Ballian and Dr Mirzeti Memišević-Hodžić, as well as numerous colleagues from forestry companies in Bosnia and Herzegovina and other, who helped with fieldwork and collecting necessary information.

ABSTRACT

The research of the three dominant linden species in Bosnia and Herzegovina as part of the DBU “MOE” 2021 scholarship program opened the door for a new perspective of these species in the Bosnian-herzegovinian economy, primarily forestry as an industrial branch. Species from the genus *Tilia* in Bosnia and Herzegovina are characterized by a wealth of intra- and interpopulation diversity, and due to their good properties (primarily resistance to long-term drought) they are considered trees of the future. The goal of the wider research project is to assess the possibilities for raising linden nurseries in Bosnia and Herzegovina in the future, so that the country can provide high-quality, highly resistant planting material, which would be used in mass afforestation. Based on the review of transparent information of forestry companies in the country, it was learned that several companies are already growing linden trees in their nurseries. This article discusses how support could be provided to forestry experts, who could possibly promote the idea of more frequent planting of trees from the genus *Tilia* in Bosnia and Herzegovina in the future. Namely, Bosnia and Herzegovina as a country has a relatively complex administrative structure, however, this should not be an obstacle to sustainably managing forests of interesting genetic importance throughout the territory of Bosnia and Herzegovina. Namely, research conducted as part of the MOE scholarship (DBU.de, 2021) (if the report of this research is reviewed) indicates that linden, especially the species *Tilia tomentosa*, should be viewed as a potential tree of the future. Since the facts indicate that linden spreads in almost all habitats in Bosnia and Herzegovina and other countries of the Western Balkans, a logical question arises: "Why not support innovative ideas in order to find sustainable solutions for the wood market on the Balkan Peninsula?". Although it was relatively difficult to obtain detailed information on the popularity of linden in nursery production based on the data available on the websites of forestry companies, it is noticeable that the websites of forestry companies are relatively transparent and aesthetically adequately arranged. Forestry companies in Bosnia and Herzegovina transparently provide contact information, so that it is possible to establish contact and inquire about cultivation, protection and sale, as well as prices of planting material. This article relies on a literature review method, as well as an overview of available relevant information on the work of forestry companies and the species that are represented in nursery production for filling forest crops, planting plantations, but also for planting in alleys, on river banks and in floodplains. The main results of the research indicate that the functioning of forestry enterprises in Bosnia and Herzegovina is sufficient to sustainably manage species of the genus *Tilia*, especially considering that the Governments of both entities are willing to support the Master Plans for Afforestation and that there is an interest in carrying out the necessary afforestation of forest land with adequate tree species, as well as supplementing forest crops with valued commercial tree species.

Keywords: *Tilia*, Plant nursery, Sustainable Management, state organisation, governmental support

INTRODUCTION

In Bosnia and Herzegovina, according to Yugoslav sources (Herman, 1971), which are the most detailed on the subject of linden, there are relatively large areas of linden, which is considered a rare noble tree in many European countries. According to an oral statement by Professor Dr. Mikic (Oral Communication, 2016), there are two large linden sites on the European continent, namely Croatia (with linden dominance on the Bilogora mountain) and Serbia (with large linden complexes on the Fruska Gora mountain). In Bosnia and Herzegovina, there are relatively large linden forest stands in the Cazinska Krajina area, with a distribution center in Bosanski Petrovac and Sanski Most, while relatively large forests of the thermophilic species *Tilia tomentosa* extend in the Neretva River canyon (Herzegovina). Bosnia and Herzegovina is a country with a very complex administrative structure, which is closely correlated with all segments of the functioning of the state, and the administrative structure of the country directly reflects on the management of forest ecosystems. However, the existence of a complex state administration is not and does not have to be a reason for unresponsive forestry, and it is possible to establish an integrated system of management supervision of tree species of special importance, with the aim of preserving important highly resistant trees of the future for future generations.

The results of the Second Large-Scale Forest Inventory in Bosnia and Herzegovina (Lojo et al., 2008), whose methodology was developed by prominent forestry experts in the country, indicate significant potential for future forest land reforestation with appropriate tree species, appropriate to the given forest ecosystems and soil conditions (its quality and history). Some of the forest land can be planted with species of the genus *Tilia*, as indicated by research within the MOE scholarships (DBE.de, 2021), within which a report was published indicating the importance of conservation and cultivation of linden trees, as well as the preservation of the genetic pool of existing linden forest stands in Bosnia and Herzegovina. In addition to this research, there is additional research indicating the importance of preserving linden for the future, in relation to protecting habitats from negative climate impacts. Thus, the authors Vejzagić, Ballian and Memisević-Hodžić (2021), in their study of the morphological diversity of

T. tomentosa trees in Bosnia and Herzegovina and Serbia, state that this species is significant in the context of climate change, while Vejzagić (2022) also points to a similar significance, describing the potential connection between climate change and the appearance of multiple bracts in the fruits of silver linden (in the short communication on discovery of multibracteate linden in Mostar).

The institutions of the Federation of Bosnia and Herzegovina and the Republika Srpska can significantly help preserve the linden gene pool, not only in Bosnia and Herzegovina, but also in the wider region consisting of the Western Balkan countries. Thus, the authorities in Bosnia and Herzegovina can support the preservation of both linden forests and individual linden trees, which are important for genetic diversity (protection from illegal logging and any fragmentation of linden habitat). The importance of the Government of the Federation of Bosnia and Herzegovina and the Government of the Republika Srpska is also reflected in the support for the potential future production of seeds and high-quality seedlings resistant to drought and temperature fluctuations, which could help preserve populations of beneficial insects, such as bees, as well as protect the

climate of local cities from overheating. Taking into account the research of Pigott (1992), who described the linden in Europe and presented information on pollen maps of Europe, according to which the linden was the dominant tree in the past, as well as the statements of Finschi et al. (2003) who explain what happened in the past with the genus *Tilia* in Europe due to the onset of the Ice Age, and if we add to the context of consideration the fact that forestry companies are obliged to do everything possible in cooperation with the academic community and authorities to ensure sustainable forest management, it is noted that there is a need to investigate the framework of potential support for sustainable linden management in Bosnia and Herzegovina. Since there is no previous knowledge about this problem (scientific articles in Bosnia and Herzegovina), and since forest management elaborates of individual forest companies are extremely large documents, which are difficult to analyze in a short period of time, there was a need to collect basic information about which forestry companies are engaged in linden cultivation in Bosnia and Herzegovina, and whether there are documents that support the idea of linden production and planting in Bosnia and Herzegovina. The research was also guided by the fact that the countries of the Western Balkans chronically suffer from a lack of statistical data (Mueller and Hofmann, 2022), and care was taken to try to collect basic information about the problem under study.

MATERIAL AND METHOD

Research obtained basic information from different forestry companies in Bosnia and Herzegovina, that are existing and functioning at the moment, but also whose management data are transparently available at the web-sites. Since the simple review method of the given information was used, the main or key terms in the website search related to: 1) territory of management, 2) main services and production aims, 3) data about the plant nurseries and 4) data about the linden production. The report data of this review work should provide background information on where the potential for wider use of linden could be explored in the future.

However, since the organization of forestry companies in Bosnia and Herzegovina is complex in accordance with the division of responsibilities into different administration units, this indicates the need to conduct basic research whether the Governments of Federation of Bosnia and Herzegovina and Republika Srpska do have certain framework for the future afforestation, concretely whether the afforestation with linden trees is has already been planned. For the purposes of this exploration, the readings of two documents, “Republika Srpska Afforestation Master Plan” (Govedar and Mataruga, 2021) and “Afforestation Manual” (Visnjic, 2024) (provided on the website of the Association of Forestry Engineers and Technicians of Bosnia and Herzegovina), were analyzed. The aim of the readings was to identify whether linden species had been planned for the afforestation in the Federation of Bosnia and Herzegovina and Republika Srpska.

Some additional data about the forest companies, such as human resources or monitoring capabilities, were added in the results, since they could indicate the potential of individual enterprise level and the institutional support together to keep linden forest resources sustainable. Finally, to be emphasized is that the research did not use data from the forestry enterprise elaborates (which consist potentially more detailed data on the amount of linden trees planned for afforestation, in the frame of Plans of afforestation), but the research focused on the publicly available data from the web source.

Studied were the websites contents obtained from the following forestry companies: 1) Public company “Forestry economic society of Zenica-Doboj Canton” Zavidovici L.l.c., 2) Cantonal

public company "Sarajevo-forests" L.l.c. Sarajevo, 3) Public company "Forests of Tuzla Canton" J.s.c. Kladanj, 4) Forestry economic society "Central Bosnia forests" L.l.c. Donji Vakuf, 5) Forestry economic society "Herzeg-bosnian forests" L.l.c. Kupres, 6) Forestry economic society "Una – Sana forests" L.l.c. Bosanska Krupa, 7) Public company "Bosnian-herzegovinian forests" e.o. Sarajevo, 8) Public company "Forests of Bosnian Drina" L.l.c. GORAZDE, 9) Forestry "Central Neretva" J.s.c. Mostar, 10) Public company „Herzegovina-Neretva forests“ L.l.c. Mostar, 11) Forestry "PRENJ" J.S.C. Konjic, 12) "FORESTRY LJUTA" L.l.c. Konjic, and 13) Forestry company "FORESTS OF REPUBLIKA SRPSKA" J.s.c. Sokolac.

After reviewing basic data about the companies, basic information related to the possibilities of improving the sustainability of linden stands and/or their individual trees, through the existing framework of institutional support and company capabilities, was clarified by the information sources from the institutional level (governmental supported documentation).

RESULTS AND DISCUSSION

The functioning of forestry companies in Bosnia and Herzegovina is to a certain extent supported by municipal (individual) and cantonal, but also Republika Srpska institutions, either through the means of those institutions directly, or through funds related to them and their services (offices), such different cooperations between forest companies and foreign organisations, who support afforestation projects in Bosnia and Herzegovina. There are different types of institutional support for the work of forestry companies in Bosnia and Herzegovina, about which a lot of information can be found on the official websites of forestry companies. Companies in general take care to publish information about partnerships and important projects on their websites. In the context of the analysis of potential addresses for seeking support in the future, when companies would seek help to harmonize their operations with the parallel negative consequences of climate change on forestry as an industry, and what also refers to support for the establishment of nursery production of resistant species of trees, from the available information it is known that support can be provided by the institutions in Republika Srpska and Federation of Bosnia and Herzegovina.

Individual forestry companies data

The first company analysed is the P.C. "Forestry economic society of Zenica-Doboj Canton" Zavidovići L.l.c.. According to the transparent content on the website, this company deals with the cultivation and protection of forests, production planning and hunting. This company has been managing Cantonal forests since 2006. There are several business units (*Olovo, Vares, Visoko, Kakanj, Zenica, Zepce, Zavidovici, Maglaj, Tesanj*, and *Business unit "Natural Monument TAJAN Zavidovici"*), which are united in five wider forestry areas (*Gornjebosansko, Olovsko, Krivajsko, Kakanjsko* and *Natron-Usorsko-Ukrinsko*). This area manages forests and forest land on an area of 183,389.20 hectares, of which 69.12% are forests with natural regeneration, 15.22% are vegetative origin forests, 9.18% are forest cultures and plantations, and 6.48% are bare and unproductive areas. The mined areas cover 21,946.40 hectares. Seed and nursery production is very successful. Seed production of silver fir, Norway spruce, Serbian spruce, green Douglas fir, Scots pine, Austrian pine, European larch, European beech, ash, sycamore, Norway maple, Scots elm, small-leaved linden, sessile oak and chequer is stable. The nurseries owned by this company are: "Olovo", "Ajdinovici", "Zepce", "Zavidovici" and "Tesanj". (SPDZDK.ba, 2025)

In Sarajevo Canton is a center of the company C.P.C. "Sarajevo-forests" L.l.c. Sarajevo, which manages the forests and forest land of Sarajevo Canton. The activities of this company are: 1. Forest cultivation, 2. Forest protection, 3. Forest exploitation, 4. Construction and maintenance of forest transport infrastructure, 5. Bioengineering, 6. Environmental projects, 7. Hunting and hunting tourism, 8. Nursery production, and 9. Various projects and collaborations. The company was founded on November 24, 1999 with the main goal of ensuring the protection of forests and forest lands in the Canton area, and to this day it fulfills the mission and vision of the company. The area of forestry is divided into two sectors, of which the first sector, which is responsible for cultivation, protection and use of forests, includes: 1. Service for cultivation and protection of forests, 2. Service for planning and analysis, 3. Service for preparation and design,

1. Service for transport and maintenance of machinery, 5. Service for maintenance of forest communications and facilities, 6. Service for hunting and tourism, 7. Service for other forest products, 8. *Srednje* Forestry Administration, 9. *Hadzici* Forestry Administration and 10. *Trnovo* Forestry Administration, while the other sector has jurisdiction over ecology and the management of protected areas, which is known as Service for Protected Areas. There are two nurseries, in Tarcin and in the settlement of Sedrenik. The two nurseries have a total area of 28,538 m², and the total capacity of these two nurseries is 700,000 seedlings. (SARAJEVO-SUME.ba, 2025) Forestry company P.C. "Forests of Tuzla Canton" J.s.c. Kladanj is a cantonal forestry company engaged in the following activities: -Forest cultivation, -Forest protection, -Seed and nursery production, -Planning and production, -Hunting, and -Non-timber (secondary) forest products (sale). The cantonal company has over 530 employees, and in addition to the Directorate, there are four business units: Forestry "KONJUH" Kladanj, Forestry "SPRECKO" Zivinice, Forestry "MAJEVICKO" Srebrenik, and Forestry "Vlasenicko" Turalici. The area manages forests and forest land on an area of 44,713 hectares. The nursery production is good developed, and the "Budim potok" nursery is characterized by the successful production of the following species/tree *generas*: silver fir, Norway spruce, blue spruce, Scots pine, Austrian pine, European larch, *Juniperus spp.* and *Thuja spp.* (JPSUMETK.ba, 2025)

Forestry company F.E.S. "Central Bosnia forests" L.l.c. Donji Vakuf deals with the following activities: -Production, -Seed production and nurseries, -Ecology and protection, and

-Forestry. Within this company there are 12 forestry units, which are named after the names of municipalities (*Jajce, Dobretici, Donji Vakuf, Travnik, Bugojno, Novi Travnik, Vitez, Gornji Vakuf - Uskoplje, Fojnica, Busovača, Kreševo* and *Kiseljak*). Twelve smaller units are included in four wider forest management areas: Forestry "Gornjevrasko", Forestry "Srednjevrasko", Forestry "Lasvansko" and Forestry "Fojnicko". The company has three nurseries: "Bugojno" Nursery, "Busovaca" Nursery and "Slimena" - Travnik Nursery. The nurseries have the following trees in the production: Norway spruce, Scots pine, Austrian pine, Bosnian pine, ash, and as for other species such as silver fir, Douglas fir, European beech, sycamore and oak, the organization of collection and production is ongoing. (SBKSUME.ba, 2025)

Next for the analysis was the F.E.S. "Herzeg-Bosnian forests" L.l.c. Kupres company, which performs the following activities: -Forest cultivation and other activities in forestry,

-Forest exploitation, -Auxiliary services in forestry, -Hunting and service activities related to hunting, -Collection of uncultivated forest fruits and products, except forest assortments,

-Processing of seeds for plant nursery material *etc.* The work within this company is carried out in the following business units: Directorate, Forestry *Bosansko Grahovo*, Forestry *Drvar*, Forestry *Glamoc*, Forestry *Kupres*, Forestry *Tomislavgrad*, Forestry *Livno*, and Work unit *RASADNIK*. The

"Przine" nursery within this company has a very successful production of the following trees: Austrian and Scots pine, Norway spruce, silver fir, *A. platanoides*, *A. pseudoplatanus*, *A. negundo*, *F. excelsior*, *S. aucuparia*, *S. aria*, *C. betulus*, *T. platyphyllos*, *P. avium*, *M. sylvestris*, and *P. pyraeaster*. (HBSUME.ba, 2025)

Forestry company F.E.S. "Una - Sana forests" L.l.c. Bosanska Krupa is a cantonal company that performs the following activities: -Utilization of forests, -Timber wholesale trade,

-Forestry (citizen) services, -Forest cultivation and protection, -Hunting, (trapping) and care of wild animals including appropriate services, -Forest cultivation and protection, -Production of other wood products, -Wood retail trade, -Cork and wicker production. The company has the following filiales: *Bihac*, *Bosanska Krupa*, *Bosanski Petrovac*, *Buzim*, *Cazin*, *Kljuc*, *Sanski Most*, and *Velika Kladusa*. This company manages 172,687.14 hectares of forests and forest lands. In addition to operations within the units, the activity is also carried out in the "Cazin" nursery. (USSUME.ba, 2025)

In the eastern part of Bosnia and Herzegovina is the center of the forest company P.C. "Forests of Bosnian Drina" L.l.c. GORAŽDE. That cantonal forestry company in the Bosnian-Podrinje Canton for its main activities has: -Planning and production, -Forest cultivation and protection, -Additional activities (SUMEBPK.ba, 2025).

Forestry "Central Neretva" J.s.c. Mostar is a forestry company based in Mostar, in the Herzegovina-Neretva Canton. The main activity of the company is the utilization and cultivation and protection of forests. The company has been operating for about 25 years and has 34 employees. (SUMARSTVOMOSTAR.ba, 2025)

Forestry company P.C. "Herzegovina-Neretva forests" L.l.c. is located in Mostar and it participate in the following activities: -Cultivation and protection of forests, -Use and sale of all products of forests and forest land, -Construction and maintenance of forest communications and facilities, -Protection, maintenance and improvement of the general useful functions of forests,

-Management of protected areas and forests with special purpose, -Planning in forestry, -Seed production, -Nursery production, and -Hunting and fishing and Tourism in forestry. The company has several units, namely: *Capljina*, *Jablanica*, *Konjic*, *Prozor-Rama*, *Mostar* and *Citluk*. (SUMEHNZK.com, 2025)

Forestry "PRENJ" J.s.c. Konjic is a company registered in the municipality of Konjic, and it participates in the following activities: -Forest cultivation, -Forest protection, -Forest utilization, -Construction and maintenance of forest transport communication, and -Nursery production. The nursery "Boracko jezero" has 2.60 ha surface. (SUMARSTVOPRENJ.ba, 2025). "FORESTRY LUTA" L.l.c. Konjic is a company whose activities are: -Production, -Cutting and export of forest wood assortments, -Sales, and -Transport. (SUMARSTVO-LJUTA.ba, 2025)

In Sarajevo there is a center of P.C. "Bosnian-Herzegovinian forests" e.o. Sarajevo, the forestry company that can be singled out as an example of a company that provides support to all the aforementioned forestry companies, and whose professional assistance in reviewing and revising project documentation and forest management fundamentals is a huge professional help and support to all forestry companies' demands (BHSUME.com, 2025). This is thanks to its different departments from which every one provides professional service of writing, revising and supporting forestry elaboration documentation related to Forest management, Forest exploitation, Forest breeding, Forest protection and all sorts of forestry economic analyses.

Large forestry company F.C. "FORESTS OF REPUBLIKA SRPSKA" a.d. Sokolac is a comprehensive forestry company in the Republika Srpska, whose activities are: -forest utilization, -service activities in forestry, wood wholesale trade, and -Wood retail trade. The company manages 1,000,608.56 hectares of forests and forest lands, of which: - forests with natural regeneration reaches 469,164.64 hectares, - degraded forests reaches 14,528.97 hectares,

- coppice forests reaches 226,336.88 hectares, - forest cultures reaches 48,687.63 hectares, - areas suitable for afforestation and management reaches 154,846.61 hectares, -areas unsuitable for afforestation reaches 68,374.82 hectares, -usurpations reaches 18,669.01 hectares. The volume of total wood mass amounts to 202,426,428 m³, of which deciduous forest wood participates with up to 122,429,391 m³, and conifers make up to 80,997,037 m³. The annual yield amounts to 5148250 m³. (SUMEREPUBLIKESRPSKE.org, 2025)

The business units of this company are: Forestry "Banja Luka", Forestry "Ostrelj-Drinic", Forestry "Panos", Forestry "Birac", Forestry "Gradiska", Forestry "Doboj", Forestry "Zelengora", Forestry "Cemernica", Forestry "Vrbanja", Forestry "Majevica", Forestry "Lisina", Forestry "Botin", Forestry "Jahorina", Forestry "Prijedor", Forestry "Ribnik", Forestry "Sjemec", Forestry "Romanija", Forestry "Drina", Forestry "Maglic", Forestry "Borja", Forestry "Visocnik", Forestry "Vucevica", Forestry "Gorica", Forestry "Treskavica", Forestry "Klekovaca-Potoci", Forestry "Milici", Forestry "Rudo", "Karst Management Center" with headquarter in Trebinje, "Research-development and project center" with headquarter in Banja Luka, "Center for seed and nursery production" with headquarter in Doboj, Forest house "Ognjiste" with headquarter in Pale, and "Directorate of Public Enterprise" with headquarter in Sokolac. The nursery production is well developed and stable, and the company has the following nurseries: "Stanovi" and "Usora" in Doboj, "Stupine" Nursery in Nevesinje, "Bisina" Nursery in Sekovici, "Gornja Puharska" Nursery in Prijedor, Trebinje Nursery (*Cupressus spp.*, *P. pinaster*, *P. halepensis*, *P. nigra*, *P. heldreichii*, *Thuja spp.*, *Cedrus spp.*, *B. sempervirens*, *P. granatum*, *L. nobilis*, *Lavandula officinalis*, palm trees, *F. ornus*, *Euonymus spp.*), and the Nursery "Petkovaca" in Brcko (50 hectares surface). (SUMEREPUBLIKESRPSKE.org, 2025)

Figure 1. Forests of Republika Srpska, with clear administrative borders among Srpska's Forestry units/area. Source: <https://sumerepublikesrpske.org/index.php/strana-1/rg-niz-ci>

Institutional support in the form of afforestation approving documents

Forestry companies in the Federation of Bosnia and Herzegovina and Republika Srpska are encouraged to implement afforestation programmes on their territory of management. Special care for the noble species of trees in the regional forest ecosystems should be anyway taken in the drought-affected areas, since they are mostly affected by climate, and so the forestry companies should take measures and plan activities to concretize protection measure, so that the forestry production does not suffer, as warned Kumar (2021).

The assumption that lindens can compete with oaks in Europe in terms of their biodiversity should be an incentive for increasingly frequent further molecular research and the search for hybrids in existing natural linden stands (populations). In order to preserve the linden trees in Bosnia and Herzegovina, and conserve the naturally occurring species with their subspecies and varieties for the future, it is necessary to learn in detail the behavior of linden trees within the species and between species, as well as the behavior of several linden species within one mixed stand. In this direction, it would be possible to go with a survey method, where the possibilities within forestry companies in the Republika Srpska and the Federation of Bosnia and Herzegovina could be investigated. If there are capacities (a sufficient number of employees) for additional monitoring of the behavioral patterns of linden trees in relation to changed environmental conditions, observing insects species that might appear (macroscopic identification on the terrain) and tracking whether the leaves and fruits of linden trees deviate from their typical appearance, there are then fundamentals for an integrated high quality health condition and vitality parameters observations. The typical appearance of lindens growing in the territory of the former Socialist Federal Republic of Yugoslavia was described by Herman (1971), and that literature source should not be neglected in the process of systematic monitoring of behavioral patterns of linden complexes in the context of climate change.

Institutional support to forestry companies in the Republika Srpska and the Federation could, therefore, help further fragmentation of linden forests, and potential planning and financing of nursery production. Each forestry company is located within the territory of Republika Srpska and Federation (nurseries in Brcko District should be investigated in the future), which is characterized by different climatic, hydrological, relief and vegetative characteristics. It is important to note that through the review of transparent information on the activities of forestry companies and the species they grow for afforestation purposes, it was noticed that there is linden cultivation, both in the continental part of Bosnia and Herzegovina (Zavidovici area) in the west-southern Mediterranean parts (Kupres) of the country. It has been observed that there is an interest in buying linden seedlings, considering that this is a very attractive species for ornamental purposes and park planting, but the question arises whether and to what extent there is interest in planting this species as part of the afforestation program, which needs to be analyzed separately in the future. In a meanwhile the forestry companies exploit lawful support in the institutional documentation, such “Republika Srpska Afforestation Master Plan” (Govedar and Mataruga, 2021) and “Afforestation Manual” (Visnjic, 2024) (provided on the website of the Association of Forestry Engineers and Technicians of Bosnia and Herzegovina).

According to the data of the Federal Forestry Administration (FMPVS.gov.ba, 2025), the support of the Federal Forestry Administration has as part of its scope of work the collection of data and the maintenance of a database on the development of all forests in the Federation of Bosnia and Herzegovina, including their inventory. The federal administration, therefore, helps forestry companies that manage state-owned forests by preparing a draft of the Forestry Program of the Federation of Bosnia and Herzegovina. In addition, this institution determines the monitoring

of the dynamics of the creation of forest management bases, which are documents that include all important information on forest management, (so forest stands as well as individual trees), which grow on public forest land. The provision of expert assistance for the development of forest management bases for forest management areas and forestry economic units in scope of companies is one of the most important assistances of this federal institution, but in addition, the development of plans and programs for extended biological reproduction of forests and programs and plans for afforestation of karst and bare forests is ensured. Establishing and maintaining registers and records of facilities for the production and processing of forest seeds and producers of forest trees and shrubs are under the authority of the institution. Monitoring the health status of forests, carrying out the work of the reporting and forecasting service and monitoring the condition and degree of forest damage is a very important function of institution, which can help in monitoring the health and condition of the habitus of the remaining linden trees, which may have the potential for cloning, i.e. more mass clonal nursery production, or which may be interesting from the aspect of seed collection for the necessary production of healthy and resistant linden seedlings. Since these trees may have commercial use in the future, and the production of linden wood for the production of furniture can potentially develop over time, it is important to familiarize all the stake-holders interested in protection of remaining linden trees and their stands with the described function of the Federal Forestry Administration, but also governmental offices in Republika Srpska. Namely, monitoring the economic condition of forestry industry, based on data obtained by cantonal administrations in the Federation of Bosnia and Herzegovina and from the Republika Srpska Governmental administration, as well as monitoring the prices of forest wood assortments and secondary forest products, including informing the public about the vitality condition of forests and the development of forestry branche, enables forestry companies to contact the Forestry Administration of the Federation of Bosnia and Herzegovina and Government of Republika Srpska at any time, in order to propose possible solutions for their local market, the needs of their partners - customers, but also to suggest species for planting in the future. The development of an adequate solution plan in front of each forestry company is the product of its engineers, i.e. experts in forestry and various fields, which means the adequacy of those proposals for consideration and support by the Federal Administration and Srpska's Government. According to the obtained data, it is clear that forestry institutional based legislation is really made by forest experts and the full implementation could serve as an example how complex administration can in final provide a healthy framework for forestry laws implementation, when all legal criteria are met.

The preparation and creation of programs in the field of forestry, which are financed or co-financed from the dedicated fund of the Federation of Bosnia and Herzegovina, is closely correlated with the preparation and implementation of scientific research activities and the transfer of knowledge in the field of forestry. New knowledge useful for forestry must, in a certain way, be forwarded to the Federal Forestry Administration, so that it has insight into the solutions offered by forestry scientists, who may work in federal forestry companies (engineers, Masters and *PhDs* of Forestry). The preparation of expert opinions for the establishment and revision of forest management areas is the domain of the Federal Administration (FMPVS.gov.ba, 2025). Also, in order to protect an area with an existing high-quality stand, it is necessary to propose it to the Federal Forestry Administration. The reason for this is that the preparation and giving of opinions for the declaration of protected forests *and* forests with a special purpose is carried out in accordance with the powers and support of the named Administration. The organization of consultations and the provision of professional assistance to cantonal administrations and cantonal forest management societies is one of the functions of the Federal Administration, on which companies can always rely, therefore, frequent communication of forestry companies is significant and useful compared to sporadic ones.

This kind of communication partially meets the recommendation of Kumar (2021). The same complex task in a form of huge support to Republika Srpska forestry units in giving the governmental office for forestry, which also supports the exchange of new scientific knowledge, ideas and solutions for existing or potential problems and helps developing cooperation between companies and institutions, as well as in terms of inter-units cooperation and strengthening awareness of the importance of protecting forests from the negative consequences of climate change. The Federal Forestry Administration and Government of Republika Srpska are supporting scientific achievements and experts recommendations from faculties for forestry (Faculty of Forestry in Banja Luka, Republika Srpska, and Faculty of Forestry in Sarajevo, Federation of Bosnia and Herzegovina), whose research projects draws the resources from the support of the Federal Ministry of Agriculture, Water Management and forestry companies themselves, and Government of Republika Srpska. Strengthening the bond between Ministries, forestry faculties and forestry companies increase the capacity to help the development of wider forestry regions. According to the Association of Forestry Engineers and Technicians (USIT.ba, 2025) of the Federation of Bosnia and Herzegovina (in Sarajevo), the support of the Croatian Forestry Society and the Faculty of Forestry of the University of Sarajevo is also very significant, not only in terms of scientific and professional assistance, but also in joint lobbying to find the best solutions for forestry as a whole and to promote solutions in the society, academic and business community. On the other hand, Faculty of Forestry in Banja Luka is host to Forest institute, which gathers forestry experts from the country and the Region, in aim to promote forest studies results and lobby for implementation of good scientific practices in the forestry of Republika Srpska (SF.UNI.BL.org, 2025).

In Republika Srpska, support is provided to the company F.C. "Forests of Republika Srpska" J.s.c. Sokolac, which is further implemented individually by all its individual business units, in accordance with the needs of those units. Due to climate differences and the presence of different ecological-phytocenological areas in Bosnia and Herzegovina, there are certain differences in the focus of forest restoration support between the Federal Ministry of Agriculture, Water Management and Forestry and the Ministry of Agriculture, Forestry and Water Management of the Republic of Srpska. For example, the percentage representation of conifers and deciduous trees is different in Federation of Bosnia and Herzegovina and Republika Srpska, so there are certain differences in the amount of planting material for forest restoration and differences in the tree species, too. For example, the focus of nursery production within the business units of the "Forests of the Republika Srpska" company for the units located in the southern municipalities is focused on species that are designated as Mediterranean, while in the case of the northern municipalities, focus in production is more on continental species. In the Federation of Bosnia and Herzegovina, for example, the need to restore forests using Mediterranean species is in close correlation with the needs of the southern and west-southern cantons, on whose territory grow the species that require Mediterranean habitat and cultivation conditions. Therefore, there are certain differences related to the flow of information such as what are the needs of forest units regarding their climate and ecological conditions. Because of the complexity of the administration in Bosnia and Herzegovina, there are also certain specifics that play a huge role in the information flow and sometimes even can affect the speed of decision making processes, i.e. whether information from business units through forestry companies must go through the processing procedure first in the cantonal institutions, and then continue its journey to the competent ministry, or (as is the case in the Republika Srpska) that information travels directly, in the sense that it does not undergo processing at some mediate levels, but can continue its journey faster to the Ministry of the Republika Srpska. Ways of supporting forestry companies with all their units, can be found on the

organized and transparent pages of the Ministry in the Republika Srpska. (VLADARS.rs, 2025, FMPVS.gov.ba, 2025)

Document “Republika Srpska Afforestation Master Plan” (Govedar and Mataruga, 2021) treats even *Tilia* species, by giving recommendations on breeding, planting, planting density index and percentage participation in the mixed forest stands. Recommendations for the linden planting are made also for the forest types, taking into consideration the habitat and vegetation characteristics for different forestry areas.

Precise data from this afforestation master plan are even given by individual *Tilia* species, as follows (Table 1).

Table 1. Surface for afforestation with *Tilia* specimens in hectares (according to Mataruga and Govedar, 2021)

Species	Dinarids (ha)	Mediterranean region (ha)	Pannonian region (ha)	Illyrian- Moesian region(ha)	Total surface for Republika Srpska(ha)
<i>Tilia cordata</i>	605,08	710,47	13,01	147,96	1.476,52
<i>Tilia platyphyllos</i>	441,83	754,06	13,55	6,86	1.216,30
<i>Tilia tomentosa</i>	301,06	1.208,87	177,76	23,16	1.710,85

At this moment it is unknown (when analysing forestry companies website content) how much of the recommended (calculated) plant material from *Tilia* genera have been planted, but it is obvious that detailed calculations exist in accordance to climate and habitat requirements.

Similar recommendations but more general, were published in Bosnia and Herzegovina in 2024 (“Afforestation Manual” by Visnjic, 2024, - provided on the website of the Association of Forestry Engineers and Technicians of Bosnia and Herzegovina), consisting detailed lists of species (non)resistant to drought, frost and temperature turbulences. Light requirements are also taken into considerations, while afforestation soil preparation process and preparation of the planting material was also described in detail. So, it is possible to conclude that governmental supported legislation and documents supporting afforestation programmes are completed by professional and fulfilling forest experts and Forestry professors works.

CONCLUSION

The institution support of the Government of the Federation of Bosnia and Herzegovina and the Government of the Republika Srpska could significantly help in the future, if the forestry companies decide to request the help of institutions for mitigating climate change. In accordance

with the reviewed literature that describes the ecological-phytocenological areas in the country, and transparent informations provided by forestry companies that manage area with small-, large- and silver-leaved linden forests, an analysis was performed in order to preliminarily suggest which forest company and under what conditions could be considered for potential feasibility study on mass linden production. In accordance with the natural habitat characteristics of the plant habitats and respecting the requirements of the species from the genus *Tilia*, which were described for the area of the former Socialist Federal Republic of Yugoslavia by the author Herman, and adding the findings of the linden research presented in the DBU.de report, which indicates a high degree of variability within and among linden populations, the recommendation of conducting wider research on establishing linden nursery for mass afforestation purpose in the future, in order to combat the negative consequences of climate change, could be given to Zavidovici-Teslic region (since natural conditions for growing linden in the nurseries already gave good results, as seen in the transparent information about nursery activity in the given company). It is interesting that the pollen maps of Europe, according to which linden pollen dominates in all habitats of the continent, raise a legitimate question whether linden cultivation in a nursery with various natural conditions in Bosnia and Herzegovina can result in quality linden trees that can adapt to all habitat conditions. Institutional support for the research of this possibility as well as various variants can be sought in the financing of scientific-research projects by forestry funds that belong to the Federal, that is, the Ministry in charge of forestry in the Federation of Bosnia and Herzegovina, and in the Republika Srpska Governmental institutions, that also could support scientific research and needed expertise. Areas such Una-Sana Canton also represents an interesting location for linden nurseries respecting the fact about existence of wider linden forest stand structures there, where the focus is on *T. tomentosa*. Successful production of *T. platyphyllos* in the Kupres, as seen from the website data collection of there active forestry company, gives hope that wider production of this species could be expected also in the future, with upcoming of higher temperatures and more frequent heat waves. Potential for further afforestation in Republika Srpska is giving optimism that the *Tilia* trees can provide better climate conditions for the local cities areas, what could results in the sustainable development of support of local forest management, forestry as industry and perseverance of local climate and biodiversity, as main fighter in mitigating climate change.

ABSTRACT

Abiotic stress factors are among the primary causes of yield losses in agricultural production, with drought and salinity being particularly prominent among these stresses. Drought stress, increasingly felt due to global warming, severely restricts plant production, especially in arid and semi-arid regions. Drought often causes soil salinization, while excessive soil salinity also leads to yield losses in many crop plants. The simultaneous occurrence of both stresses leads to even more serious negative effects on plant development and yield. Therefore, understanding the tolerance mechanisms that plants develop under such combined stress conditions is crucial for developing effective agricultural strategies. This study evaluated the relationships between biological markers that play a role in combined stress tolerance in eggplant under combined drought and salinity stress conditions and that provide concrete indicators of the multifaceted stress responses. As a result of evaluations using correlation analysis and a polar heatmap, strong relationships were identified among shoot dry weight (SDW), malondialdehyde (MDA), proline, total anthocyanins, total phenolic compounds, some antioxidant enzyme activities, and the K⁺/Na⁺ ion ratio. The polar heatmap comprehensively revealed the relationships between biomarkers in stress responses in terms of direction and intensity. These findings demonstrate that these parameters are important biomarkers reflecting the level of tolerance to combined stress in eggplant and provide guidance for selecting genotypes with high stress tolerance or for planning future studies.

Keywords: antioxidant enzymes, biological markers, combined stress, eggplant, ion homeostasis,

INTRODUCTION

Drought and salinity are among the most significant abiotic stresses, negatively impacting plant production and causing serious problems resulting in yield loss. Losses are particularly high in vegetable species with high water content. This situation is even more critical in arid and semiarid regions with limited water and land resources and inadequate water use (Hussain et al., 2024). Researchers estimate that the area affected by drought is increasing and that yield losses will increase further unless measures are taken to mitigate the negative effects (Golldack et al., 2014; Cao et al., 2023). Drought, particularly the effects of climate change, is currently exacerbating the severity of these stresses.

Drought and salinity, two primary stress factors in agricultural production, often occur simultaneously. In arid areas, soil salinity develops much more rapidly than in rainy regions due to the combination of factors such as low rainfall, high evaporation, irrigation with poor-quality water, and inadequate drainage (Zelm et al., 2020). These stresses lead to physiological

and biochemical problems in plants, such as loss of turgor, decreased stomatal conductance, decreased chlorophyll content, ion imbalance, decreased photosynthetic capacity, and lipid peroxidation, protein denaturation, and DNA damage due to increased reactive oxygen species (ROS) (Kumar et al., 2016; Hasanuzzaman et al., 2019; Kıran and Baysal Furtana, 2023). Plants develop various defense mechanisms against these adverse conditions, such as antioxidant enzymes (SOD, CAT, APX, GR), proline, and phenolic compounds (Kıran and Baysal Furtana, 2023; Sharma et al., 2023).

The physio-biochemical responses of plants to combined stress are remarkable, and their responses to these complex stress conditions are generally unpredictable by their responses to single stresses. However, existing studies on the effects of combined stress are quite limited. Eggplant (*Solanum melongena* L.) is an important vegetable species widely grown in tropical and subtropical regions of the world due to its low calorie content and rich vitamin and mineral content. Eggplant is reported to be moderately tolerant to drought and moderately sensitive to salinity (Kıran et al., 2022; Cebeci et al., 2025). While plant responses to drought and salinity have been studied separately, the responses that occur under combined stress conditions have been more clearly defined (Kıran and Baysal Furtana, 2023). In this context, characteristics that can be considered biomarkers, which are distinctive indicators of stress responses, have been identified, and their importance as biomarkers in revealing the effects of combined stress has been emphasized. Indeed, biomarkers play a critical role in determining plant tolerance not only to single stress conditions but also to combined stress conditions.

In this context, for the purpose of this study, examining prominent biomarkers that can be used to assess biological responses to drought and salinity stress in eggplant using correlation and polar heatmap analyses will significantly contribute to both elucidating tolerance mechanisms and providing guiding data for genotype selection.

MATERIALS AND METHODS

The study was carried out as pot experiments in a controlled glass greenhouse (22–26/18–22°C day-night temperature, 50–55% humidity). Seeds of open-pollinated 'Kemer' eggplant variety were used in the study. Seeds were sown in vermiculite-perlite (1:1) mixture, and 30 days later, seedlings with 3–4 true leaves (DAS-30 days after planting) were transplanted (8 seedlings/pot) to 7 L pots containing medium textured soil (N: 0.18%, P: 3.60%, K: 0.86%, pH: 7.75, EC: 1.28 dS m⁻¹). Seedlings were irrigated at field capacity until stress treatments. Field capacity was determined by leaving the pots saturated in water for 48 hours and draining the gravity water. Drought and salt stress treatments were initiated at 37 DAS according to a randomized plot design with four replicates. Control plants were irrigated at field capacity (FC), drought stress (DS) pots were irrigated at 60% FC, salt stress (SS) pots were irrigated with water containing 50 mM NaCl, and combined stress (DS + SS) pots were irrigated at 60% FC with 50 mM NaCl. Tap water (EC: 0.42 dS m⁻¹) was used for control and DS irrigation. The study was terminated at 75 DAS and sampling was performed.

Harvested plants were dried at 65°C until they reached constant weight and weighed to obtain SDW values. K⁺ and Na⁺ analyses were performed by microwave digestion (Kacar and Inal, 2008). Total phenolic content was determined by the Folin-Ciocalteu method (Singleton and Rossi, 1965), proline by Bates et al. (1973) and anthocyanin were determined according to the method of Mancinelli et al. (1975). Lipid peroxidation (malondialdehyde (MDA) as a lipid peroxidation product) was measured using the methods of Velikova et al. (2000) and Heath and Packer (1968). Superoxide dismutase (SOD), Catalase (CAT), and Glutathione reductase (GR) activities were determined using standard enzyme assays (Beyer and Fridovich, 1987; Çakmak and Marschner, 1992).

Data Analysis

Relationships between biological markers were visualized using a correlation diagram, and hierarchical clustering between data sets was represented by a polar heat map. Both visualizations were prepared using OriginPro 2024 (OriginLab Corporation, USA) software.

RESULTS AND DISCUSSION

In this study, correlation analysis was conducted to examine the relationships among traits considered as biomarkers. The correlation table reveals the multifaceted relationships between some important biochemical and physiological parameters examined in response to drought, salinity, and their combined treatments. Images of plants exposed to drought and salt stress, both individually and in combination, are presented in Figure 1, while a heatmap visualizing the correlation data is presented in Figure 2. Biomarkers were identified using a previous study (Kıran and Baysal Furtana, 2023) by selecting traits showing significant differences against stress conditions using ANOVA (analysis of variance) and then using PCA (principal component analysis) to identify parameters effective in distinguishing groups.

Figure 1. Eggplant plants exposed to single and combined applications of drought and salinity stress

According to correlation analysis, a positive relationship was observed between SDW (shoot dry weight) and anthocyanin (Anthc), while negative and significant correlations were found with proline, total phenolic compounds (Phenol), glutathione reductase enzyme (GR), and MDA. The positive relationship between SDW and anthocyanin levels may reflect the plant's adaptation to stress conditions by synthesizing anthocyanins. Anthocyanins, a potent antioxidant, protect cells from oxidative stress. Under combined stress, high anthocyanin accumulation contributes to the relative maintenance of plant metabolic activities and growth. Therefore, SDW increases under stress may occur. Results confirming this were also reported by Dabravolski et al. (2023).

Figure 2. Correlation heatmap of biomarkers evaluated under combined stress ($p < 0.05$).

However, proline generally accumulates in plant cells in response to stress, enabling osmoregulation. However, under the combined conditions of drought and salt, which create extreme stress, proline accumulation may indicate that the plant's growth capacity is reduced and that it is diverting necessary metabolites to stress tolerance. Therefore, a negative correlation with SDW is observed. Similarly, phenols also act as antioxidants under stress conditions; however, the severity of stress indicates that the plant is under severe oxidative stress and growth processes are suppressed. This indicates an inverse correlation with SDW.

On the other hand, MDA accumulation, an indicator of membrane lipid peroxidation, indicates that cell damage increases further under severe stress and negatively affects plant growth. This explains the negative correlation with SDW. The GR enzyme, which is effective in neutralizing MDA, is activated to reduce oxidative stress. However, high GR activity indicates that the plant is under intense stress and growth is significantly inhibited. In other words, plants expend energy on the stress response rather than growth to limit cellular damage; hence, a negative correlation with SDW arises. Indeed, Qadir et al. (2022), Soujoud et al. (2024) and Kiran et al. (2025) also reported negative relationships between SDW and proline, phenol, GR, and MDA.

The positive and significant correlation of proline with MDA and phenolic compounds is crucial for stress tolerance. Furthermore, while an increase in MDA levels indicates the severity of stress, proline accumulation also increases to alleviate the plant's stress load and reduce cellular damage (Kiran et al., 2025). In other words, as stress increases, both MDA and proline levels increase. Conversely, phenolic compounds, which are potent antioxidants, accumulate more, strengthening the plant's antioxidant defenses. This suggests that under combined stress, the plant simultaneously activates adaptive responses. Similar findings were also reported by Patanè et al. (2022) and Soujoud et al. (2024).

Phenolic compounds exhibited a significant positive correlation with MDA and GR. In stressed plants, phenolic compounds protect cells from reactive oxygen species (ROS) damage during oxidative stress (Carvalho et al., 2021). The positive correlation of phenolic compounds with MDA suggests that as stress intensity increases, the plant strengthens its antioxidant defenses by increasing phenolic compound synthesis (Zahedi et al., 2023). On the other hand, the GR enzyme plays an important role in combating oxidative stress. The positive correlation

of phenolic compounds with GR suggests that the plant simultaneously activates enzymatic and non-enzymatic antioxidant systems. This suggests that stressed plants activate both metabolic and enzymatic defense mechanisms simultaneously.

Among the antioxidant enzymes, SOD was found to have a significant negative correlation only with anthocyanin, while CAT showed a significant positive correlation only with the K^+/Na^+ ion ratio. SOD and CAT are enzymes that play important roles in antioxidant defense mechanisms against stress in plants. The negative correlation between SOD and anthocyanin in plants under combined stress indicates that the plant detoxifies some of the ROS under stress via anthocyanins, and therefore, SOD activity becomes relatively less critical. Indeed, similar findings were reported by Bigham Soostani et al. (2025) and Ullah et al. (2025).

On the other hand, the positive correlation between CAT and the K^+/Na^+ ratio suggests that the K^+/Na^+ ratio is an indicator of cellular ion balance and salinity tolerance. The positive correlation of CAT enzyme with this ratio suggests that under combined stress, including salinity stress, the plant increases CAT enzyme activity to maintain ion homeostasis and detoxify ROS (Zafar et al., 2024). Furthermore, the positive correlation of GR with proline suggests that proline not only maintains osmotic balance in plants under combined stress but also contributes to the antioxidative defense system together with GR. Furthermore, MDA was found to have a strong and positive correlation with GR. This suggests that as lipid peroxidation increases, oxidative stress in the cell also increases, which, in turn, enhances the conversion of GSSG to GSH, leading to further stimulation of GR (Rao et al., 2024).

Figure 3. Polar heatmap with dendrogram created to display associations between biomarkers evaluated under combined stress

The dendrogram heatmap visualizes similarities and relationships between parameters, revealing which traits change together. SDW, MDA, proline, GR, anthocyanin, and K^+/Na^+ are grouped in the same cluster in blue tones; blue indicates negative correlations or low values between these parameters. The presence of these parameters in the same cluster suggests that

these traits play a role in similar biological and metabolic processes in response to stress conditions. For example, the presence of SDW, MDA, proline, GR, anthocyanin, and K^+/Na^+ levels in the same cluster indicates that the plant simultaneously activates its growth, enzymatic and non-enzymatic antioxidant defense, and osmotic regulatory mechanisms (Sharma et al., 2022). This minimizes cellular damage and protects growth and metabolic functions (Dabravolski et al., 2023).

In contrast, the presence of GR and SOD in a different cluster suggests that this trait has a more independent response. This direct clustering suggests that these enzymatic antioxidant systems work together and in conjunction, while the observation of different shades of blue reflects that the two enzymes have relatively different activity levels in the stress response. This suggests that the capacity of enzymatic antioxidant mechanisms increases in the combined stress environment, where the most severe stress is observed in plants, thus enabling plants to achieve higher tolerance to combined stress. Indeed, it has been previously reported that plants activate their enzymatic antioxidant systems more intensely under stress. (Rao et al., 2024).

Similarly, the presence of phenolic compounds and the CAT enzyme in the same cluster and their positive correlation with high values reveal that non-enzymatic and enzymatic antioxidant mechanisms are activated simultaneously (Bigham Soostani et al., 2025). This finding suggests that plants provide more effective defense against oxidative stress by using antioxidant mechanisms more intensively under combined stress conditions (Sharma et al., 2022).

CONCLUSIONS

Correlation analysis between biological markers and a dendrogram heatmap displaying their relationships enabled a multifaceted assessment of biochemical and physiological responses to combined stress conditions. The polar heatmap and correlation analyses revealed that enzymatic biomarkers, in particular, are the most reliable and important markers for understanding stress responses. However, for practical applications, it has been demonstrated that more easily measurable parameters, such as phenolic compounds, proline, the K^+/Na^+ ratio, and MDA levels, can be used to assess stress tolerance. Therefore, they are recommended as reliable and practical indicators for assessing stress tolerance and selecting tolerant genotypes.

ABSTRACT

Geranium (*Pelargonium graveolens*) is a perennial, herbaceous shrub-like aromatic plant species that contains essential oil in its leaves and flowers. The essential oil of the geranium (*Pelargonium graveolens*) plant is widely used in the perfume and cosmetics industries. The demand for high-quality geranium essential oil is increasing day by day. However, in Turkey, geranium plants grown for landscaping purposes are not cultivated for the essential oil industry. As a result of verbal discussions with the essential oil industry in Turkey, it has been concluded that the widespread cultivation of geranium plants is necessary. It is understood that the export potential of lavender essential oil currently imported from abroad is also high. The rose-scented “Bourbon” variety of the lavender plant is preferred in the perfume and cosmetics industries. However, since this variety is a hybrid, it does not produce fertile seeds, meaning seed production is not possible. Therefore, the plant is propagated vegetatively. To promote the widespread cultivation of geranium in Turkey, it is necessary to develop and optimize a rapid, healthy, and mass micro-propagation method. This project was conducted to determine the appropriate nutrient medium combination for *in vitro* propagation of the geranium plant and to identify the suitable rooting medium for *in vitro*-propagated plantlets. To serve the propose MS medium combined with 1 BAP (mg/l) + 0.01 IBA (mg/l), 2 BAP (mg/l) + 0.02 IBA (mg/l) and Vacin & Went medium combined with 0.5 BAP (mg/l) + 0.01 IBA (mg/l), 1 BAP (mg/l) + 0.01 IBA (mg/l), 2 BAP + 0.02 IBA (mg/l). Results revealed that MS medium supplemented with 0.5 BAP+ 0.01 IBA mg/l gave the best result regarding number of shoots, leaves and shoot length and MS0 media was good enough for rooting.

Keywords: Geranium, micropropagation, *in vitro*, shoot and leaf formation, number of leaves, shoot length

INTRODUCTION

Pelargonium spp. belongs to the *Geraniaceae* family and is commonly known as geranium. There are approximately 280 species within the genus *Pelargonium*, and these species are predominantly native to South Africa (Kellen, 1983). According to research, *Pelargonium zonale* was introduced to Europe in the early 1600s (Craig, 1960; Ewart, 1981). Although there are 280 different species in the *Pelargonium* genus, only a limited number of them are commercially important in terms of flower color, species, leaves, and growth habits. Although these commercially important species differ according to the literature, they are generally divided into four groups: *Pelargonium x hortorum*, *Pelargonium x domesticum*, *Pelargonium peltatum*, and scented geraniums *Pelargonium* sp.

Pelargonium forms part of many high-grade perfumes, has antifungal, insect repellent and antibacterial activity, so it has widespread use in the field of medicinal and agricultural

chemicals. The oil is non-toxic, non-irritating and generally does not cause sensitization in humans. The oil is a sought-after ingredient in cosmetic products such as soaps, colognes, lotions and creams because of its "rose-like" floral odour. It stands out with its relaxing effects in the field of aromatherapy; its effects on conditions such as stress and anxiety have also been reported. Geranium oil has GRAS (Generally Recognized As Safe) status by the US Food and Drug Administration (FDA) and is used as a flavor additive (Boukhatem et al., 2013). Thanks to its anti-microbial properties, it is considered as a natural preservative agent in food preservation. In addition, leaves and flowers, tea, sweets, jelly, syrups, and tobacco are used as flavoring.

Pelargonium plants are cultivated for their floricultural value as well as their use as a source of essential oil. World production of *Pelargonium* oil is estimated at 250-300 tons, while the demand is over 800 tons per year. Therefore, both for the production of oil for various industries and for the utilization of *Pelargonium graveolens* for various other purposes, it is clear that there is a great demand for *Pelargonium* plants, which requires large-scale cultivation. In summary; *Pelargonium graveolens* is a plant of high economic and industrial importance not only for its aroma chemical composition and strong biological activity profile, but also for its economic production potential, global demand and versatile uses. It offers a strategic agricultural and industrial opportunity for potential producers such as Türkiye.

Pelargonium is traditionally propagated by stem cuttings or by seed. Regarding propagation by seed; although seed-propagated varieties of *Pelargonium* have become a popular alternative, they lack some of the agronomically superior and important characteristics found in vegetatively propagated varieties, such as semi-double flowers and lack of fragmentation (Harney, 1982). It is also important to emphasize that *Pelargonium* seeds are very expensive (Stokes Growers Guide, 2000). When the issue come to propagation by cuttings it is worth of stating that a limited number of cuttings can be taken from each mother plant. Propagation by cuttings carries a high risk of infectious diseases, e.g. soil-borne pathogens (*Fusarium*, *Pythium*) (Mastalerz, 1971). In addition, there is a seasonal dependence, so that the taking of cuttings is sensitive to environmental factors such as temperature and light; therefore, year-round production is difficult. In summary, propagation by cuttings has significant limitations in practical use. *Pelargonium* propagation from seed can be difficult for several reasons. Due to cross-pollination it can be difficult to know whether the seed is of the true type. The long seed germination time can also be a problem for some geranium species. In addition, propagation from seeds can alter the genetic composition of the plant, which may result in undesirable changes in terms of oil composition or yield. This may make it unsuitable as a source of oil for the perfumery, cosmetic or pharmaceutical industry, where it is mainly grown.

The aforementioned obstacles associated with large-scale propagation of *Pelargonium* can be overcome by using *in vitro* propagation techniques. For example the use of *in vitro* propagation techniques in the propagation of high-value *Pelargonium* plants is of great importance for obtaining pathogen-free plants (Laughner, 1993). Compared to the above-mentioned negative aspects of seed and cuttings propagation, *in vitro* nodal culture can be used to obtain *Pelargonium* plants that are true to their name and have genetic stability and stability. In this sense, it is important to optimize an efficient and cost-effective, sustainable propagation and acclimatization protocol for *in vitro* micropropagation of *Pelargonium* plants and this research was carried out for this purpose.

MATERIAL AND METHOD

Plant material

Plant material used in the experiments was introduced from abroad by Güney Agripark Ltd and all work was carried out in the laboratories and greenhouses of Güney Agripark Ltd. The donor plants from which the explants were taken were watered regularly every day and treated with a 1.5% fungicide solution every two weeks until they were used as explant sources, ensuring they were grown in a physiologically balanced and healthy manner.

Culture media and hormonal treatments

Murashige & Skoog (1962) (MS) and Vacin & Went (1949) stock solutions were used as basic media for macro, micro and vitamin compositions. Stock solutions were prepared by dissolving the appropriate amount of macro and micro nutrients and organic supplements using distilled water. Similarly, BAP and IBA growth regulator stock solutions were prepared in a 1/1 ratio (1 mg/1 ml) and dissolved with 1 N NaOH or ethanol and the total volume was adjusted using distilled water. The pH of the medium was adjusted to 5.7 with 0.1 N NaOH or 0.1 N HCl as required and 0.7 g/l agar was added to the medium and boiled to mix the agar with the medium. The concentration of sucrose used in the medium was 3%. Finally, the medium was sterilized by autoclaving at 121°C for 20 minutes under 2 atm. pressure.

In the study, combinations were created using two different culture media and three different hormone concentrations (see Table 1). Each different combination was repeated five times.

Table 1. Media compositions used in the research

<u>MS 0</u>
<u>MS 0.5 mg/l BAP + 0.01 mg/l IBA</u>
<u>MS 1 mg/l BAP + 0.01 IBA</u>
<u>MS 2 mg/l BAP + 0.02 mg/l IBA</u>
<u>Vacin & Went 0</u>
<u>Vacin &Went 0.5 mg/l + BAP 0.01 mg/l IBA</u>
<u>Vacin &Went 1 mg/l BAP + 0.01 mg/l IBA</u>
<u>Vacin &Went 2 mg/l BAP + 0.02 mg/l IBA</u>

Sterilization

Healthy explants taken for sterilization were first washed with tap water for 30 minutes. The fresh shoots of the washed explants were cut at a length of about 10 cm including the internodes and internodes. The washed and cut explants were placed in a sterile cabinet and treated with 70% ethanol for 1 min and then a drop of Tween-20 was added, and sterilization experiments were carried out to determine the appropriate sterilization conditions by keeping them in 20%, 30% NaClO concentrations in 5, 15 and 20 minutes.

Culture conditions

Sterilized nodes were cultured in MS medium and Vacin & Went medium prepared at different hormone concentrations. One node explant was used for each culture. Culture jars were incubated under a cold white fluorescent lamp (4000 lux) at 24 ± 2 °C with 16/8 h light/dark cycles. The media were renewed two weeks after the internodes were planted. Data on the number of internodes that started to proliferate were recorded after four weeks of culture.

RESULTS AND DISCUSSION

The sterilization tests table and results for *Pelargonium graveolens* are given in Table 2. As can be seen from the table, the best result for sterilization of *Pelargonium graveolens* plants was obtained by sterilization with 30% concentration of sodium hypochlorite for 20 min and the rate of contamination-free plants was 90%.

Table 2. Results of different sterilization treatments

NaClO concentrations	5 min.	15 min.	20 min.
% 20	% 50	% 65	% 80
% 30	% 60	% 75	% 90

Sterilization results clearly showed that increasing the NaClO concentrations and duration increase the percentage of no contaminated plants in other words number of clean plants.

Regarding the experiments conducted the find out the best media and hormone concentration and combination, as also stated above, MS (Murashige & Skoog, 1962) and Vacin & Went (1949) media were used as basic media for *in vitro* shoot regeneration experiment. Agar (0.7%) was used as solidifier and sucrose (3%) was used as carbon source and the results obtained are given in the table below.

Table 3. Results obtained for *in vitro* shoot regeneration experiments in different media combinations

Media composition	Number of Leaves	Number of Shoots	Shoot Length
MS 0	3,0	2,0	2,5
MS 0.5 mg/l BAP 0.01 mg/l IBA	10	3,5	4,0
MS 1 mg/l BAP + 0.01 mg/l IBA	6,0	2,0	3,0
MS 2 mg/l BAP + 0.02 mg/l IBA	7,5	2,5	2,0
Vacin & Went 0	3,0	1,2	1,1
Vacin &Went 0.5 mg/l BAP + 0.01 mg/l IBA	6,9	2,3	3,1
Vacin &Went 1 mg/l BAP + 0.01 mg/l IBA	4,8	1,6	2,2
Vacin &Went 2 mg/l BAP + 0.02 mg/l IBA	4,2	1,4	2,0

As can be seen from the table, the best result in terms of the parameters examined was obtained in MS 0.5mg/l + BAP 0.01mg/l IBA medium.

Figure 1. Some pictures from *in vitro* shoot regeneration studies

Figure 2. Shoots obtained from the nodes used as explants in *in vitro* culture studies

Results obtained revealed that the best results regarding number of leaves, number of shoots and shoot length obtained MS basic medium was better than Vacin & Went medium if one makes comparison between two basic media (MS and Vacin & Went). As it also clearly seen from the results given in Table 3, low amount of BAP combined with low amount of IBA gave better results than high amount of BAP and IBA in MS basic medium yet again in terms of number of leaves, number of shoots and shoot length. As it is known, the classical rule for shoot propagation: cytokinin dominance stimulates axillary buds, low auxin promotes shoot elongation, whereas high auxin pushes to the root or callus. The chosen dose/ratio, the ratio of 0.5 mg/l BAP to 0.01 mg/l IBA, provides a high but below toxic threshold cytokinin effect for axillary shoot stimulation, while very low IBA allows shoot elongation without forming weak

callus. Therefore, the ratio of 0.5 mg/l BAP to 0.01 mg/l IBA might have resulted in better shoot number, leaf number and shoot length at the same time.

As it is also known MS medium provides a richer supply of total nitrogen (especially $\text{NO}_3^- + \text{NH}_4^+$) and macro/micro elements compared to Vacin & Went. This composition is generally more favorable for rapidly dividing meristematic tissues and axillary shoot emergence. High nitrate and balanced ammonium favour an increase in protein synthesis/chlorophyll and thus leaf number + shoot length. When the same BAP/IBA ratios are tested on VW medium, the performance of Vacin & Went medium can therefore be expected to lag behind due to lower osmotic/ionic support and micronutrient differences. In addition, VW is essentially designed for different nutritional needs such as orchid cultures; total nitrogen, ammonium/nitrate balance and sulphate/phosphate levels are different from MS. In this sense, the high basal salinity and microelement profile of MS in shrubby, fast vegetative mass-forming aromatic species such as Geranium usually gives more shoots + longer shoots. Therefore, the proliferation/extension observed in VW at the same hormone ratios may have been weak in comparison.

Subculturing studies were conducted which was conducted to increase number of plants in MS basic medium combined with 0.5 mg/l BAP + 0.01 mg/l IBA as stated medium and hormone combinations gave better results than other combinations. In subculture micro-propagation studies using MS 0.5 mg/l BAP + 0.01 mg/l IBA medium, 6 times more plants were obtained at the end of the 4th subculture as can be seen from down given pictures.

Figure 2. Increased number of plants in jars after subculturing

Regarding *in vitro* rooting studies; MS0 was used in the rooting stage since the plants were observed to root even in the propagation stage. 100% success was achieved. The rooting of the shoots obtained was realised 7 days after rooting in MS0 medium. The average root number of the shoots was 3.75 cm and the average root length was 1.30 cm in the specified environment.

For acclimatization studies, *in vitro* rooted plantlets rooted in hormone-free MS medium were removed from the culture jar and washed under tap water to remove agar from the roots. The washed plantlets were planted in vials containing sterilised sand, soil and peat mixture (2:2:1) and covered in the greenhouse for about two weeks for acclimatisation. Then, the cover was removed and kept in the greenhouse for two weeks.

Figure 3. *In vitro* propagated Pelargonium plants which were acclimatized in the greenhouse by removing the cover

After the cover was removed, the plants were kept in the greenhouse for two weeks and then placed in pots and placed outdoors under normal climatic conditions. Stated acclimatization protocol was found to be very effective and successful for *in vitro* micropropagated *Pelargonium* plants. Planting in a mixture of sterilized sand:soil:peat (2:2:1) during acclimatization seems to have worked very well and this may be due to the substrate properties and the proportions used. Probably the sand (2 parts) improved drainage and aeration and prevented hypoxia in the roots, the soil (2 parts) provided mechanical adhesion and basal nutrient buffer, and the peat (1 part) with its high-water retention capacity may have prevented water stress to the *in vitro* formed leaves accustomed to high humidity.

CONCLUSIONS

At the end of the research, a sustainable micropropagation, rooting and acclimatization method with a high multiplication coefficient for obtaining healthy and mass plant material in *Pelargonium* plants under *in vitro* conditions has been successfully developed. This study demonstrates that MS medium supplemented with 0.5 mg/l BAP and 0.01 mg/l IBA is optimal for the *in vitro* micropropagation of *Pelargonium graveolens*. The findings can facilitate large-scale propagation of elite cultivars and support Türkiye's efforts to expand its aromatic plant industry and reduce dependence on imported essential oils.

ABSTRACT

Medicinal plants have long been used to treat various diseases. Ginger (*Zingiber officinale* Roscoe), a herbal plant from the *Zingiberaceae* family, is one of these plants. It is used as a spice and medicine in the treatment of cancer; cardiovascular diseases; diabetes; and some other diseases such as colds, nausea, asthma, and coughs. Polyphenols and flavonoids, which are found in high amounts in leaves, stems and rhizomes, play an important role in the pharmacological effect of ginger. These polyphenols and flavonoid compounds are natural sources of antioxidants. Ginger rhizome is a rich source of these antioxidants and is also naturally used in food preservation due to its antimicrobial activity. Due to all these unique properties, the demand for ginger is increasing in the world markets. Due to the rapid increase in soil diseases, the yield of ginger, which is an expensive product, decreases in rhizome production. Tissue culture method provides disease-free plants. In addition, a large number of plants can be obtained in a very short time with tissue culture technique. The present research was aimed to determine the optimum conditions for ginger production by tissue culture. For *in vitro* shoot multiplication, ginger shoots were sterilized, and explants cut approximately 0.5-0.8 cm were cultured in 35 mL jars containing different hormones and dosages of MS medium supplemented with 30 g L⁻¹ sucrose and solidified with 2.5 g L⁻¹ gelrite. MS medium supplemented with different types of plant growth regulators (IBA and IBA + IAA combinations), and medium MS0 as a control were used for shoot multiplication. MS medium supplemented with 4.5 mg L⁻¹ BAP was found to be the best media composition regarding number of shoots, leaves and shoot length and MS0 medium was found to be good enough for rooting.

Keywords: Ginger, micropropagation, *in vitro*, shoot and leaf formation, number of leaves, shoot length

INTRODUCTION

Medicinal and aromatic plants have recently attracted a great deal of attention worldwide and that is why there is a high demand for medicinal and aromatic plants. In response to the increase on some diseases such as covid, cancer; cardiovascular diseases; diabetes, medicinal and aromatic plants are considered as a rich source of important compounds to be used in drug development. Due to that fact some medicinal and aromatic plants in danger of extinction due to this overharvesting (Kumari and Priya, 2020). One of the most important medicinal and aromatic plant is ginger (*Zingiber officinale* Roscoe) which belongs to family *Zingiberaceae*. Ginger is valued as an important spice thanks to its nutritional and medicinal properties (Devina et al., 2016) and that is why it is cultivated in many countries, including India, China, Japan, Indonesia, Australia, Nigeria and the West Indie, generally as a perennial plant. Although different authors reported different numbers about the total number of species and genera it is

assumed that there are 51 genera and 1500 species (Newman, 2001). Ginger has many fibrous roots, leafy pseudostems and an underground root rhizome, which is used for many purposes such as vegetative propagation and storage of foodstuffs (Ravindran and Nirmal Babu, 2005). Ginger is being sold as an herbal supplement in the United States, as reported by Gang and Ma, (2008). It is a known fact that Ginger (*Zingiber officinale* Roscoe) is being used as a spice and in traditional medicine for the treatment of some diseases such as cancer; cardiovascular diseases; diabetes; and several other diseases. It has been also reported to help alleviate severe virus symptoms during the COVID-19 pandemic and reduce the recovery time in these patients. It is reported that polyphenols and flavonoids, which are found in high amounts in leaves, stems and rhizomes, play an important role in the pharmacological effect of ginger since these polyphenols and flavonoid compounds are natural antioxidant sources. Since ginger rhizomes are a rich source of these antioxidants, they are also naturally used in food preservation due to its antimicrobial activity.

Due to all these unique properties, the demand of ginger in the world markets is increasing considerably. In this sense, abundant and high quality starting material is needed in a short time. Ginger is an infertile species not suitable for seed production. Therefore, it cannot be propagated sexually as its rhizomes are used for vegetative reproduction. Since rhizomes are an economically utilized part of the plant, the high use of ginger rhizomes as starting material for growing the plant in the next growing season has a negative impact on its supply in the market. More over quite some of the diseases are easily transmitted and transmitted from rhizomes through vegetative propagation. In addition, the bulkiness of ginger rhizomes as planting material makes their processing costly and laborious (Shaaban et al, 2023). Therefore, *in vitro* propagation can be a good alternative for propagation of ginger (Behera et al., 2010). Long-term vegetative propagation of ginger, which is mostly produced by rhizomes, causes weakening of the rhizomes. Ginger is also one of the most difficult plants to propagate from seed due to poor seed set with flowering (Mosie, 2019). For these reasons, it is necessary to produce a high amount of disease-free plants in a short time for commercial ginger cultivation. On the other hand, using *in vitro* techniques, it is possible to produce millions of disease-free plants with the same genotype in a short time. In this study, it was aimed to develop a protocol for rapid and high-rate *in vitro* propagation of ginger plant using different plant growth regulators. With the tissue culture method, pathogen-free plant production may be possible after optimization of the media, thousands of plants can be obtained in a short time with high reproduction rate, year-round production can be carried out without seasonal restrictions, genetic homogeneity can be achieved in the reproduction material thanks to this reproduction method and as a natural result of all these, yield increase in production can be achieved and quality plant material suitable for the pharmaceutical and cosmetic industry can be obtained.

MATERIAL AND METHOD

Healthy ginger rhizomes were obtained from Gazipaşa, Antalya and all studies were carried out in the laboratories and greenhouses of Güney Agripark Ltd. Ginger rhizomes were kept in a moist, sterilized sand medium at $25 \pm 2^{\circ}\text{C}$ in the dark for 3 weeks to germinate the buds and the rhizome was allowed to germinate. Buds (1-1.5 cm) sprouted from the rhizome were cut from the rhizome and used as explants. The cut buds were washed thoroughly with a few drops of liquid detergent and 2-4 drops of Tween 20 under running tap water for 30 minutes. After washing, rhizome sprouted bud explants were surface sterilized with 70% (v/v) ethanol for 1 min. These explants were then surface sterilized with two different concentrations of commercial bleach (20% and 30%) with two drops of Tween-20 for 5, 15 and 20 min immersion time. Surface sterilization of explants with 70% ethanol for 1 min was considered as control treatment. Finally, surface sterilized explants were rinsed 4-5 times with sterilized distilled water. After sterilization explants cut approximately 0.5-0.8 cm were cultured in 35 mL jars

containing different hormones and dosages of MS medium supplemented with 30 g L⁻¹ sucrose and solidified with 2.5 g L⁻¹ gelrite. The pH of all media was adjusted to 5.8 using 0.1 N NaOH or HCl solutions before adding gel rite. They were then autoclaved at 121 °C and 2 atm pressure for 20 min. For all cultures, a light intensity of approximately 4000 lux was maintained in the culture room at 25 ± 2 °C under a 16 h photoperiod.

In micropropagation studies, Murashige & Skoog (1962) (MS) basic medium was used and the following hormones and combinations were tested (see Table 1.)

Table 1. MS basic media and hormone combinations used in propagation studies

MC	MS0
M1	1.5 mg L ⁻¹ BAP
M2	2.5 mg L ⁻¹ BAP
M3	3.5 mg L ⁻¹ BAP
M4	4.5 mg L ⁻¹ BAP
M5	0.4 mg L ⁻¹ BAP + 0.2 mg L ⁻¹ IAA
M6	0.6 mg L ⁻¹ BAP + 0.2 mg L ⁻¹ IAA
M7	0.8 mg L ⁻¹ BAP + 0.2 mg L ⁻¹ IAA
M8	1.0 mg L ⁻¹ BAP + 0.2 mg L ⁻¹ IAA

The media were evaluated according to the following parameters.

- Number of shoots/explant
- Number of leaves/shoot
- Shoot length (cm)

The medium composition which was found to be successful in terms of above stated parameters was used for propagation and was also used to determine the propagation coefficients depending on the number of subcultures.

RESULTS AND DISCUSSION

Regarding sterilization studies, as it can be clearly seen from Table 2, the best result in the sterilization studies of *Zingiber officinale* plants was obtained by sterilization at 30% concentration of sodium hypochlorite for 20 minutes, as can be clearly seen in the table below. Under the specified conditions, the success rate of the plants to remain sterile was measured as 96%.

Table 2. Results obtained from sterilization studies

NaOCl doses	5 minutes	15 minutes	20 minutes
% 20	% 60	% 70	% 80
% 30	% 70	% 80	% 96

NaOCl is a chlorine-based oxidative disinfectant; it kills or removes microorganisms by oxidizing proteins and cell membranes. 20% NaOCl and/or short duration (5-15 min) applications provided lower sterility. The reason for this may be that the lower concentration does not provide sufficient penetration, especially in hard tissues on the rhizome surface. 30% NaOCl is found to be a high enough concentration for sterilization application. When used in combination with Tween-20, it overcomes the waxy layer on the leaf and rhizome surface,

allowing better contact of the disinfectant with microorganisms. The 20-minute duration provided sufficient time to destroy surface contaminants (especially fungal spores and bacterial biofilms). Shorter duration may be ineffective against spores and resistant microorganisms.

The effects of different growth regulators added to the MS medium on shoot proliferation of *Zingiber officinale* is given in the Table 3 below based on hormone dosages and combination.

Table 3. The effects of different growth regulators added to the MS medium

Code	MS medium	Number of shoots/explant	Number of leaves/shoot	Shoot length (cm)
MC	MS0	1.00	3.25	2.73
M1	1.5 mg L ⁻¹ BAP	4.25	10.50	3.18
M2	2.5 mg L ⁻¹ BAP	6.00	11.00	2.93
M3	3.5 mg L ⁻¹ BAP	6.25	12.00	3,85
M4	4.5 mg L ⁻¹ BAP	8.00	15.50	4.10
M5	0.4 mg L ⁻¹ BAP + 0.2 mg L ⁻¹ IAA	2.25	7.75	4.03
M6	0.6 mg L ⁻¹ BAP + 0.2 mg L ⁻¹ IAA	3.25	9.75	3.33
M7	0.8 mg L ⁻¹ BAP + 0.2 mg L ⁻¹ IAA	4.00	8.25	3.38
M8	1.0 mg L ⁻¹ BAP + 0.2 mg L ⁻¹ IAA	3.00	6.50	2.28

As clearly seen in Table 3, the best results in terms of the investigated parameters were obtained with the addition of 4.5 mg L⁻¹ BAP to the MS medium. This result indicates that cytokinins, especially 6-Benzylaminopurine (BAP), effectively trigger meristematic cell division and stimulation of axillary buds. The activity of BAP is known to result from the capacity of adenine-derived cytokinins to accelerate DNA synthesis, increase protein translation and regulate cellular metabolism. However, high concentrations of BAP may lead to undesirable physiological results such as hyperhydricity, callus formation and unbalanced organogenesis. In this study, 4.5 mg L⁻¹ was determined as the optimal level and BAP concentrations above this level may cause adverse effects, although it was not tested in this present study. Regarding IBA and IAA hormone combinations, BAP + IAA combinations did not improve the multiplication coefficient at the dose-composition tested in the study and even caused a decrease in some parameters.

Figure 1. Some pictures from shoot proliferation studies

The total number of plants and growth coefficients obtained as a result of subculturing at 4-week intervals using MS + 4.5 mg L⁻¹ BAP medium are given in the Table 4.

Table 4. Results of different subcultures by using MS + 4.5 mg L⁻¹ BAP medium on obtained number of plants

<i>Zingiber officinale</i>	Number of Plants (Number)	Multiplication Coefficient
Start	300	
1st Subculture	800	2,6
2.Subculture	3600	4,5
3.Subculture	15120	4,2
4.Subculture	68040	4,5

Regarding rooting of obtained shoots in jars, the plantlets that reached a certain size were directly transferred to MS0 medium for rooting and were rooted without the need for any plant growth regulator (see Figure 2).

Figure 2. Rooted ginger plantlets in MS0 medium

In vitro shoots that have "reached a certain size" in development naturally synthesise auxins, mainly IAA (indole-3-acetic acid), in their apical/axillary meristems and nodal regions and transport them basipetally (tip to base). This endogenous auxin influx can provide the threshold level necessary for rhizogenesis (root initiation) for MS0 medium without the addition of external auxin.

Regarding acclimatization studies; *in vitro* grown plants were washed thoroughly with tap water to remove agar from the roots. They were then immersed in 0.3% fungicide solution for 15-20 min and then washed with tap water. The plantlets were then transplanted into the vials filled with peat. Care was taken not to damage the roots when the plants were transplanted

into the vials, they were moistened regularly at periodic intervals and acclimatized successfully under *ex vitro* conditions (see Figure 3 and 4).

Figure 3. Ginger plantlets which were removed from jars and washed thoroughly with tap water to remove agar from the roots

Figure 4. The plantlets which were transplanted into the vials filled with peat.

In vitro propagated ginger plants, which were regularly watered and acclimatized in peat-filled vials, were transferred to greenhouse conditions after 2 months, completed their growth and development in greenhouse conditions and the first rhizomes were successfully obtained after 8 months. The developed acclimatization protocol was successful because it managed the three critical risks of acclimatization (excessive water loss, root/crown rot, substrate incompatibility) with the correct sequence and appropriate protective steps. In this sense, agar removal → protective fungicide → peat medium → controlled humidity → greenhouse after 2 months → rhizome in 8 months. It is possible to say that the acclimatization method developed has a scientifically consistent and technically feasible sequence; in particular the principles of complete removal of agar, avoidance of root injury and gradual stressing explain the reported successful acclimatization and rhizome output at 8 months.

CONCLUSIONS

This research successfully established an efficient micropropagation protocol for *Zingiber officinale* using MS medium supplemented with 4.5 mg L⁻¹ BAP was found to be the best media composition regarding number of shoots, leaves and shoot length and MS0 medium was found to be good enough for rooting. This composition significantly enhanced the number

of shoots, shoot length, and leaf development, offering a viable solution for mass propagation of disease-free and genetically uniform ginger plants. The study contributes to the commercial cultivation of ginger and provides a platform for further biotechnological interventions such as *in vitro* conservation, genetic transformation, and secondary metabolite production. Further studies may explore the rooting phase and acclimatization of *in vitro* plantlets under greenhouse conditions.

ABSTRACT

Honey is a highly valued, nutritious natural product well-known healing benefits. Due to their unique features and limited availability, monofloral honeys (from one predominant floral source) are highly demanded and prized. Unfortunately, this economic incentive brings along fraudulent activities, such as misrepresenting a common honey as a rarer monofloral type or adulteration with sugar syrups and low-grade honey. Therefore, the authentication of botanical origin and accurate detection of adulteration are critical for consumer trust and regulatory compliance. Although there are several approaches, such as physicochemical profiling, organoleptic evaluation, and spectral analysis, melissopalynology (microscopic pollen analysis) is the gold standard for verifying floral origin. Nevertheless, traditional methods of examining pollen in honey are slow, prone to human error, and subjective. In recent years, deep learning (DL) methods (particularly convolutional neural networks, CNNs) have achieved significant performance at microscopic pollen authentication. Along with study domains such as allergology, archeology, and forensics, honey authenticity analysis also benefits from these techniques. This study aims to evaluate the current status and future trends of these techniques to identify new opportunities to improve effective and reliable honey botanical origin authentication.

Keywords: Monofloral honey classification, Pollen classification, Melissopalynology, Microscopy, Deep learning, Explainable AI

INTRODUCTION

Honey is defined as a natural sweet substance produced by honey bees (*Apis mellifera*). Botanical Origin refers to the specific plant or flower sources from which the bees collected nectar. Monofloral/unifloral honey types are predominantly from one nectar source, often requiring a pollen proportion of over 45% for most species, and command a higher market value due to their unique organoleptic and therapeutic properties (Haidamus et al., 2019). Honey obtained from various types of flowers is referred to as multifloral/polyfloral, which has pollen grains from several plants, none of which are predominant, and is generally less expensive (Geană et al., 2020; Tsagkaris et al., 2021).

Monofloral honeys are highly valued not only for their unique sensory characteristics but also for their distinct healing effects such as antioxidant, antibacterial, anti-inflammatory, liver-protective, gastroprotective, and anticancer properties, which are directly influenced by their botanical origins (N. Li et al., 2024; Mărgăoan et al., 2021). Medicinal effects of monofloral honeys have been reported in several studies, highlighting their potential in functional foods and complementary medicine (Cianciosi et al., 2020). Antiproliferative effect of Manuka honey on murine melanoma, colorectal and human breast cancer cells; weight, adiposity, and triglyceride level reduction effects of Acacia honey are some of the reported results of the

previous studies in the domain (Mărgăoan et al., 2021). Due to these benefits, monofloral honey is a high-value commodity and is the third most adulterated food products globally (N. Li et al., 2024).

Dilution with sugar syrups or other cheaper substances (Banach et al., 2025; X. H. Zhang et al., 2023), mislabeling multifloral honeys as monofloral types, or blending with low-grade honey are the most commonly applied adulteration techniques to increase the yield and profit margins. These fraudulent practices not only compromise consumer trust but also pose significant challenges for regulatory authorities aiming to ensure food safety and authenticity (Ahmed, 2024; Da Silva et al., 2016).

Honey adulteration primarily poses numerous risks in terms of consumer health by compromising food safety standards. The consumption of honey adulterated with sucrose may increase the risk of diabetes, and undeclared components may be toxic or cause allergies (Fakhlaei et al., 2020; Samat et al., 2018). Consumers purchase honey based on its declared botanical and geographical origin, expecting specific taste, nutritional value, and medicinal properties. False labeling and adulteration deceive consumers, undermining their trust in the product and the market.

Honey authentication refers to the processes, including verification of true botanical and geographical origin and ensuring that it is free from any adulteration with sugar syrups and low-grade honey (Brar et al., 2023). Sensory (taste and smell) evaluation and visual (color depth, luster, and viscosity) inspection; analysis of physicochemical parameters such as acidity pH, electrical conductivity, specific quality indicator contents (moisture, brix, proline, 5-hydroxymethylfurfural (HMF), melissopalynological analysis (manual identification and quantification of pollen grains in microscopic images of honey samples) are widely used conventional methods within the scope of honey authentication (X. H. Zhang et al., 2023).

The botanical source significantly influences honey's chemical composition, flavor, aroma, nutritional value, health benefits, and market price. Within the scope of adulteration detection, honey botanical origin authentication is the critical process to verify the declared plant source of honey to ensure its quality, authenticity, and market value. Melissopalynology is the gold standard traditional method for authenticating the botanical origin of honey. While newer methods exist, melissopalynology remains the preferred analysis method that fulfills official standards and norms. For instance, this manual process is still cited as the most accurate method and the only one which fulfills official standards and norms in certain countries, such as Germany (Viertel and König, 2022). Despite this significance, due to its manual nature, melissopalynology is labor-intensive and slow. Besides, it requires considerable expertise and is prone to human error, which restricts its scalability for large-scale quality control.

In the last decade, artificial intelligence (AI), particularly deep learning (DL), based methods, emerged as powerful tools to enhance botanical origin authentication processes. By automating pattern analysis and image recognition, rapid and highly accurate AI-based solutions, often exceeding 90% and sometimes reaching near 100%, have been reported (Viertel and König, 2022).

Despite significant advancements, there are remaining challenges, such as substantial risk of misclassifications for certain edge cases (e.g., morphologically similar pollen grains) (Banach et al., 2025). Ensuring that the accuracy and generalization capability of a model in botanical origin authentication is at the highest possible level is the indispensable requirement for effectiveness and reliability. Starting from here, in this study we will review the recent notable research studies of AI-based pollen grain analysis with a critical review of their methodologies and findings.

PALYNOLOGY AND MELISSOPALYNOLOGY

The study and analysis of pollen grains, known as palynology, is a broad field that plays an important role in various disciplines, including allergology, archaeology, and forensics, as well as honey production. Daily measurement and estimation of atmospheric pollen concentrations are critical processes to track allergenic pollen levels, enabling patients and healthcare providers to plan outdoor activities and manage treatments. Identification of fossil pollen preserved in sedimentary archives is a powerful proxy for reconstructing past vegetation and climate. Pollen specimens are valuable in forensic analysis, aiding in identifying individuals or locations due to their unique characteristics.

As the automated and rapid pollen identification solutions are required by all these domains, the focus of AI-based pollen identification studies is not limited to honey botanical origin identification. The common aspect of all these studies is using image datasets of several pollen types to train the models, to be used for the recognition of a certain pollen type. These images may be collected from various sources, including pollen-related books and websites, museum specimens, environmental samples, and directly from plants or honey samples.

Training of deep learning models needs pollen datasets with significant diversity and scale. Therefore, a small number of research groups constructed new datasets of the pollen types of their regions and even made them available (open access) to address this need. Table 1 presents the datasets commonly used by the studies in this domain.

Table 1. Pollen Datasets

Reference	Dataset	Source	Size and Types
(Gonçalves et al., 2016)	Polen23E	Honey (Brazil)	23 type of 805 images
(Astolfi et al., 2020)	Pollen73S	Flowers (Brazilian Savannah)	73 type of 2523 images
(Battiato et al., 2020)	Pollen13K	Airbone samples	5 types of 13.000 images
(Valiente et al., 2025)	Pollen24SP	Honey (Spain)	24 types of 32,285 images
(Tsiknakis et al., 2021)	Cretan Pollen Dataset (CPD)	Flowers (Crete)	20 type of 4.034 images
(Holt, 2020)	New Zealand Pollen Dataset (NZPD)	Mostly honey (New Zealand and the Pacific)	46 types of 19.500 images
(Rostami et al., 2025)	Great Basin Desert (Nevada) Pollen Dataset(GBDPD)	Herbarium collection, (UNRMNH)	6 types of 1353 images
(C. Li et al., 2023)	Urticaceae Family Dataset	Flowers and herbarium collection (NBC, Leiden)	5 types 6472 images

CPD: Cretan Pollen Dataset, NZPD: New Zealand Pollen Dataset, GBDPD: Great Basin Desert Pollen Dataset, UNRMNH: Reno Museum of Natural History, NBC: Naturalis Biodiversity Center

MACHINE LEARNING (ML) IN POLEN GRAIN ANALYSIS

Early studies utilizing artificial intelligence in pollen grain analysis used ML algorithms considering several physicochemical properties (Kibar, 2024; Mateo et al., 2021), mineral profiles (Al-Awadhi Mokhtar and Deshmukh, 2023), and spectral characteristics(Ahmed, 2024; Zhao et al., 2020) as features for the training of the models. Inspired by mellisopalynology,

some of those ML-based studies used extracted features from microscopic pollen images (Gonçalves et al., 2016; Marcos et al., 2015; Travieso et al., 2011).

In Gonçalves et al. (2016), a pollen dataset (POLEN23E), which was also constructed within the scope of the study, is used. This annotated image dataset for the Brazilian Savannah consisted of 805 images of 23 pollen types (Figure 1). The achieved overall accuracy performance using features such as shape, color, and texture was around ~64% accuracy, with higher than 90% accuracy for some pollen types.

Figure 1: Sample images for each of the 23 pollen types a)Anacardiaceae: *Schinus terebinthifolius*; b-c) Arecaceae: b- *Arecaceae*; c- *Syagrus*. d-e) Asteraceae: d) *Chromolaena laevigata*; e) *Tridax procumbens*. f) Bignoniaceae: *Fridericia florida*. g) Burseraceae: *Protium heptaphyllum*. h) Combretaceae: *Combretum discolor*. i-j) Euphorbiaceae: i) *Croton urucurana*; j) *Mabea fistulifera*. k-n) Fabaceae: k) *Anadenanthera colubrina*; l) *Dipteryx alata*; m) *Mimosa somnians*; n) *Senegalia plumosa*; o) Lamiaceae: *Hyptis*. p-q) Myrtaceae: p) *Eucalyptus*; q) *Myrcia*. r) Poaceae: *Urochloa decumbens*. s) Rubiaceae: *Faramea* t-u) Sapindaceae: t) *Matayba guianensis*; u) *Serjania laruotteana*. v) Urticaceae: *Cecropia pachystachya*. w) Vochysiaceae: *Qualea multiflora* (Gonçalves et al., 2016)

Although accuracy performances exceeding 90% were achieved in similar studies (Marcos et al., 2015; Travieso et al., 2011) using morphological features such as texture and contour, ML-based methods have some drawbacks. Feature extraction work is labor-intensive and time-consuming. Besides, this feature extraction work needs to be repeated for the new pollen types to be included in the scope of the updated models. To overcome these drawbacks, domain studies in the last five years have focused on deep learning methods, which find the determinative features and patterns in the dataset on their own.

DEEP LEARNING (DL) IN POLEN GRAIN ANALYSIS

Due to its capability to extract patterns from high-dimensional data, DL has been widely applied to complex tasks such as computer vision. Convolutional Neural Networks (CNNs) are a class of deep neural networks particularly well-suited for image classification tasks. Their powerful neural network architectures automatically extract mid-to high-level features from image datasets. A significant challenge for training CNNs from scratch is the need for massive datasets, which are often unavailable in specialized fields like palynology. Transfer learning

addresses this challenge by utilizing the low-level feature (e.g., edges, colors, textures) identification capability of pre-trained models and fine-tuning them for the specific task by using small training datasets. In this section, we will review the recent notable research (see Table 2) that employs CNNs and transfer learning for the analysis of pollen grains. Along with the newly developed ones, the used CNN models in these studies are AlexNet (Krizhevsky et al., 2012), VGG (Simonyan and Zisserman, 2014), MobileNetV2 (Sandler et al., 2018), ResNet (He et al., 2015), InceptionV3 (Szegedy et al., 2016), Xception (Chollet, 2017), SE-ResNeXt (Hu et al., 2018), NASNet (Wistuba et al., 2019), Vision Transformer (ViT) (Dosovitskiy et al., 2020), DenseNet (Huang et al., 2017), EfficientNet (Tan and Le, 2021), and ResNeSt (H. Zhang et al., 2022).

Sevillano et al. (2020) collected 19,500 images of 46 pollen types from New Zealand and the Pacific regions, applied transfer learning with AlexNet for feature extraction and trained a linear discriminant classifier for final classification. Using 10-fold cross-validation, they achieved 97.86% accuracy on the validation set. Before the training stage, cropping with minimum padding, resizing, and rotation data augmentation techniques were applied to the dataset. Classification was more challenging for taxa with fewer images. Tsiknakis et al. (2022) applied transfer learning with four CNN architectures: InceptionV3, Xception, ResNet, and Inception-ResNet along with ensemble learning (hard and soft voting) to combine the predictive power of base models on the Cretan Pollen Dataset (CPD), which comprises more than 4000 pollen-grain images of 20 pollen types. Zero padding to standardize the image sizes, randomly adding Gaussian noise, linearly adjusting contrast and brightness, rotating, and translating the image were also applied as pre-processing and data augmentation techniques. Ensemble learning improved robustness and sensitivity. They achieved 97.5% accuracy as the best performance by an ensemble of all models with soft voting, but this model performed poorly (weighted average AUC score of 0.52) for pollen grains extracted from honey samples. The misclassifications of models on both datasets were mainly attributed to morphological similarities (Figure 2). On the other hand, the effect of other elements (sugar, proteins), probable state (joined, swollen), and the distribution of the grains in honey sediment were also commented as the probable factors causing the steep drop in the performance for the honey-based samples. Therefore, the importance of honey-based datasets and robust pre-processing techniques was emphasized.

Figure 2. Pollen-grain images of pollen types with similar morphological characteristics (Tsiknakis et al., 2022)

Using 10,000 images of 40 pollen species of the Great Basin Desert, Nevada, USA, Rostami et al. (2023) applied transfer learning to pretrained CNN models, AlexNet, VGG-16, MobileNet-V2, ResNet, ResNeSt, SE-ResNeXt, and Vision Transformer (ViT) with various depths. An accuracy of 97.24% was achieved as the best performance by ResNeSt-110. They

also developed a new CNN-based model with six layers and achieved an accuracy of 91.87%. Z-stack imaging, cropping, resizing, noise removal, rotation, flips, zoom, rescaling, noise addition pre-processing and augmentation techniques were applied before the training stage.

Valiente et al. (2023) constructed a dataset of 16 types of 19,000 images obtained from Spanish citrus and rosemary honeys. They annotated the pollen images with a Java-based tool, HoneApp, which was also developed within the scope of their study. Along with eight CNN models (VGG16, VGG19, InceptionV3, Xception, ResNet50, DenseNet201, MobileNetV2, EfficientNetV2M), they also developed a new CNN-based model, PolleNetV1, with their dataset. InceptionV3 was the best-performing model with 97.99% accuracy. Their new model, PolleNetV1, which had significantly fewer parameters, faster, and achieved 95.66% accuracy. Another important aspect pointed out in this study is the 1–2% increase in accuracy performance for all the models before and after data augmentations of applying some affine transformations (rotation, translation, and reflection) to original images to increase the number of samples in the dataset. As the continuation of this study, Valiente et al. (2025) improved the dataset to 24 pollen and non-pollen classes of 32,285 images by including more Spanish honey types, and named it POLLEN24_SP. They also improved their PolleNetV1 model to PolleNetV2 and developed a lightweight variant of it (PolleNetV2.mobile). The best performance achieved by the nine CNN models (VGG16, VGG19, ResNet50, InceptionV3, Xception, DenseNet201, EfficientNetV2M, MobileNetV2, NASNet) was 98.03% by EfficientNetV2M. PolleNetV2 and PolleNetV2.mobile had 97.10% and 96.48% performances, respectively.

Rostami et al. (2025) applied nine CNN models: DenseNet201, EfficientNetV2S, InceptionV3, MobileNetV2, ResNet50, ResNet101, VGG16, VGG19 and Xception on 1,353 pollen images of 6 similar types collected from herbarium specimens at the University of Nevada, Reno Museum of Natural History (UNRMNH). All of the models achieved $\geq 96\%$ accuracy. The ResNet101 model had the best accuracy performance of 99%. Conversion to grayscale, thresholding, and morphological operations for noise removal, random rotations, flips, and zooming were used as pre-processing and data augmentation techniques.

Shamrat et al. (2024) used the New Zealand pollen dataset which has more than 19,000 images of 46 pollen types. They applied duplicate and poor-quality image removal, after which the number of images left was 19,612. Other pre-processing techniques applied were non-local means denoising and gamma correction to preserve fine texture and enhance contrast and normalize luminance, respectively. Along with four CNN models (AlexNet, MobileNet V2, VGG16, ResNet50) to be used with transfer learning, they also developed a new custom CNN model PollenNet, which achieved the best accuracy performance of 98.45%. The best performance achieved by the other models was 81.6% by MobileNet V2. They also applied Grad-CAM and saliency maps Explainable Artificial Intelligence techniques, to generate the heatmaps that reveal the regions and specific pixels with the most influence on the model's decision, respectively.

Figure 3 presents the correctly classified samples' Grad-CAM heatmaps, as red and blue regions representing the pixels which the model considers as the most and the least influential, respectively. This type of model explanation also serves as proof that models recognize and leverage distinct features of the images consistently, such as the red regions of central pollen structure in 'FucosporaFusca' and the edges in 'Kunzea'.

Figure 3: Grad-CAM heatmaps demonstrate PollenNet’s accurate feature detection across various correctly classified pollen grains (Shamrat et al., 2024)

Figure 4 presents the Grad-CAM heatmaps of misclassified samples. Two of these cases, for *Lepto* and *Kunzea* with similar morphology, highlight that the misclassification might have been caused by the similarity that the model was unable to cope with to discern the types.

Figure 4: Grad-CAM heat maps on specific misclassified images by PollenNet showing regions impacting its predictions (Shamrat et al., 2024)

DISCUSSION AND CONCLUSION

The accuracies of over 95% performance at pollen grain recognition make the CNN-based DL models strong candidates as effective solutions for honey botanical origin authentication. Several remarkable points contribute to the accuracy performances. Improved performance by ensembling the models contributed to the accuracy (Tsiknakis et al., 2022). For the studies, involving the development of a new CNN model (Rostami et al., 2023; Shamrat et al., 2024; Valiente et al., 2023, 2025), the only one with a better accuracy than the CNN and transfer-learning based approach was (Shamrat et al., 2024), which had a dataset of size greater than the others. In (Valiente et al., 2023), the significant increase (1-2%) in performance obtained after data augmentation of the same data set clearly highlights the importance of the factors contributing to the reliability, size, and diversity of the dataset. None of the pre-trained CNN models came into prominence, considering the studies evaluated. Morphological similarity of pollen grains was commented on as a significant challenge in all the studies. Tsiknakis et al. (2022) and Shamrat et al. (2024) emphasized this fact, by exposing the misclassified pollen types with similar morphologies. Multi-modal models, combining standard microscopic image data with other physicochemical or spectral measurements (data fusion), could be a good approach for distinguishing between species that have subtle morphological differences, as commented on by the studies in the domain other than the ones we evaluated (Rajendran & Mahadevan, 2025).

Explainable Artificial Intelligence (XAI) is another critical point that significantly enhances the reliability of deep learning (DL) models in pollen grain classification by assisting in confirming whether the deep learning model is making classification decisions based on the actual, relevant morphological features of the pollen grain, rather than irrelevant artifacts. Besides, the misclassification examples exposed in Shamrat et al. (2024), as Grad-CAM visualizations, highlight the capability of XAI-based approaches to indicate regions that a model fails and guide efforts to improve the model or the dataset.

Email: z.s.dehghani.f@gmail.com

ABSTRACT

Thionins are an ancient family of plant-derived antimicrobial peptides, where their activity is dependent not only on their overall structure, but also on the presence of highly conserved sequence motifs. These motifs have been conserved through wide taxa and suggest strong evolutionary pressure to maintain critical domains possibly involved in membrane disruption and pathogen recognition. While the biological roles of thionins are well studied, there are few studies investigating molecular explanations for motif conservation. An exploration of these conserved elements would afford a better understanding of the structure-function correlation of thionins and their significance in adaptation in plant defense systems. In this study, a total of twenty-six thionin proteins sequences of plants family belonging to different orders were retrieved from NCBI with FASTA format. Amino acids sequence patterns were created using MEME (Multiple Em for Motif Elicitation; version 5.5.8) and MAST (Motif Alignment and Search Tool; version 5.5.8) programs on <http://meme-suite.org>. The program was designed to report the 10 most robust motifs of 10 to 30 width Amino acids, occurring zero or once per sequence, with detection spanning between 2 to 600 sites among proteins belonging to plants family. Based on the results, motif 1 (30aa, E-value= 9.9e-165) and motif 3 (19aa, E-value= 8.3e-064) obtained as the most common motifs, which were shared 24 plant species.

Motif 1: PDVHEYCKLGCASSVCGNJSTLQNSDASEI

Motif 3: MEVKSVMCVLILGLVLGQ

These common conserved motifs among different plants' species confirmed thionin protein functional similarities.

Keywords: thionin protein; Bioinformatics; Conserved motifs; plants

INTRODUCTION

Thionins are a family of small, cationic antimicrobial peptides uniquely found in plants, serving as important components of crop innate immune responses against pathogens. Their rich disulfide bond network and stable tertiary structure have led to the evolutionary preservation of specific amino acid sequence arrangements -termed "conserved motifs"- which are critical for the potent antimicrobial activity of thionins and for their ability to interact with pathogen cell walls (Höng et al., 2021). Accurate identification of these motifs using modern bioinformatics applications allows the development of novel strategies for engineering disease-resistant plants. Recent advances in motif analysis tools such as MEME Suite and comparative protein family platforms have enabled a comprehensive exploration into thionin motifs across diverse plant species (Bailey et al., 2009; Almaghrabi et al., 2019; Liu et al., 2025). These studies revealed that conserved thionin motifs maintain structural integrity while providing powerful antibacterial and antifungal properties, frequently through interactions mediated by specific sequence fingerprints (Li et al., 2021; Stotz et al., 2013). While numerous investigations have characterized thionin physicochemical properties, systematic comparative motif analyses across botanical taxa remain underexplored (Höng et al., 2021).

From an applied standpoint, mapping and engineering key thionin motifs represent powerful tools for plant disease control. Incorporating thionin genes harboring functional motifs into susceptible crops via transgenic or genome editing approaches has been shown to boost resistance against major phytopathogens, including *Fusarium*, *Xanthomonas*, and *Pseudomonas* (Hoshikawa et al., 2012; Goyal and Mattoo, 2016; Khan et al., 2025). Integration of cutting-edge bioinformatics motif discovery methods with advanced genetic editing platforms such as CRISPRa can yield resistant varieties with minimal off-target genomics changes (Khan et al., 2025). This study aims to identify and compare conserved thionin motifs in selected plant species, analyze their structure–function relationships using modern bioinformatics tools, and suggest practical applications for development of resistant crops in plant protection programs and global food security initiatives.

MATERIALS AND METHODS

Thionin protein sequence retrieval

The Thionin protein Reference Sequences (RefSeq) of different plant species were downloaded from NCBI (<http://www.ncbi.nlm.nih.gov>) in FASTA format (date received: October 2024). Among the Thionin plant sequences, those with the range of 115-135 amino acids were designated by the NCBI filters, and one sequence from each plant's genus was selected as their representatives for further analyses. Total data consisted of twenty-six plant species, which are listed in Table 1 with their families, accession numbers, and abbreviations.

Table 1. The list of twenty-six thionin plant species analyzed in current study

Conserved motifs analyses

The motifs of protein sequences were created using the program MEME (Multiple Em for Motif Elicitation; version 5.5.8) and MAST (Motif Alignment and Search Tool; version 5.5.8) at website <http://meme-suite.org/> (Bailey et al. 2009) to study the variation of thionin in different plants' species. Among tools for defining perceptible domains, MEME has some advantages, so that it is able to recognize smaller individual motifs and more divergent patterns. The program was set to report the 10 most robust motifs of 10 to 30 width amino acids, occurring zero or once per sequence, with 2 to 600 sites among the proteins belonging to thionin plants' species.

RESULTS AND DISCUSSION

In a group of protein-related sequences, a sequence pattern is observed repeatedly known as a conserved motif. Patterns and sequences analyses of thionin conserved motifs was done by MEME. MEME represents motifs as position-dependent letter-probability matrices, which assign the probability of each possible letter at each position in the pattern, though motifs in MAST are characterized as position-dependent scoring matrices and define the score of each possible letter at each position in the pattern. Ten conserved motifs of each thionin species was

identified by MEME which their scores, E-values and the number of motifs' species are listed in Table 2.

Table 2. Characterization of ten motifs of different plants' thionin analyzed in this study

Index	Best possible match	Site	Width	E-value
1	PDAHEYCKLGCASSVCGNJSTLQNSDESEI	24	30	2.0e-166
2	EAKSCCPNTTARNCYNVCRFPGTSRP	14	26	1.6e-127
3	MEGKSVIMCVLVLGLVLGQ	24	19	8.0e-064
4	VERCTNACSRFCTKGSGKA	22	19	9.2e-054
5	LCGCKIISGPTCPPGYPKJ	13	19	8.5e-045
6	CALKCLKKCJIPKSNT	8	16	1.2e+000
7	EGCVDSCSETCAKK	5	14	1.0e+002
8	WEDCWILLPT	2	10	2.0e-002
9	KEKCEHHPF	2	10	4.0e+003
10	FCLRFGGCPPGPP	2	13	8.3e+006

These findings also showed that all species shared at least four identical motifs (Figure 1).

Figure 1. Motifs of thionin protein in plants. The MEME motifs are shown as different boxes. The E-value of a sequence is the expected number of sequences in a random database of the same size that would match the motifs as well as the sequence.

Nucleotide and protein sequences comprise patterns or motifs that have been preserved through evolution since they are crucial to the function or structure of the molecule. In proteins, these conserved sequences may be involved in the binding of the protein to its substrate or to another protein, may contain the active site of an enzyme, or may determine the three-dimensional structure of the protein (Brejová et al., 2000). Members of protein families are often characterized by more than one motif (on average, each family has 3-4 conserved regions), which increases the certainty that a protein has been assigned to a precise family (Nevill-Manning et al., 1998).

These analyses showed that motifs 1 and 3 were common in 24 samples whose logos are shown in Figure 2, while motifs 8, 9, and 10 were only shared in two plant species. Moreover, the least observed motifs belonged to *Vigna angularis*, with only one motif.

ABSTRACT

Thionins are a family of small proteins exclusive to higher plants. These proteins typically consist of 45-48 amino acids, with 6–8 cysteine residues that form 3-4 disulfide bonds. They include phoratoxins and viscotoxins. Alpha- and beta- thionins are related to each other while gamma thionins, despite having a superficially similar structure, belong to a distinct category of proteins now identified as plant defensins. In this examination, the thionin protein reference sequences (RefSeq) from various plant species within the Brassicales order, including *Brassica napus*, *Brassica rapa*, *Raphanus sativus*, *Eutrema salsugineum* and *Capsella rubella* were obtained from the National Center for Biotechnology Information (NCBI) in FASTA format. Structural analyses of thionin protein were performed using online tools available on the EXPASY website. Primary and secondary structures of thionin proteins for each Brassicales species were estimated using ProtParam and SOPMA, respectively. The tertiary structure prediction and visualization of thionin were performed by PHYRE2 server. Thionin protein in all Plants ranged from 115 to 134 amino acids in length. The theoretical isoelectric points and molecular weight were calculated at a range of 5.36-8.75 and 12196.93-1431872 Da, respectively. A High aliphatic index suggested that thionin exhibit structural stability in Brassicales plant samples. The GRAVY values of this protein designated thionins are generally membrane-associated (hydrophobic) proteins in nature, except for *Arabidopsis thaliana*, which is globular (hydrophilic protein). The Instability index analysis revealed thionins in *Brassica rapa* and *Capsella rubella* were stable, whereas those in other Brassicales samples were classified as unstable. SOPMA analysis showed that alpha helices and random coils were the dominant secondary structural elements while extended strands were occasionally distributed in the proteins. Tertiary structure predictions using PHYRE2 indicated significant similar structure among plant thionins.

Keywords: Brasicales; ProtParam, SOPMA; Structural analysis; Thionin

INTRODUCTION

Thionins represent a crucial family of small, cysteine-rich peptide-like proteins with diverse functions, mostly in plants, in which they provide defense against entire sets of microbial pathogens, including bacteria and fungi. Through binding and disrupting membranes, these proteins are thought to mediate their antimicrobial activity and can be associated with the plant's defense arsenal. Structurally, thionins possess characteristic folds stabilized by specific arrangements of disulfide bonds that maintain their compact structure along with conserved α -helices and β -sheets that play vital roles in their bioactivity and stability (Stec, 2006).

The Brassicaceae family consists of economically important cruciferous plants with *Arabidopsis* and *Brassica* species that are known to generate diverse defense peptides, thionins, among others. Though thionins are known for their importance, the lack of profiled comprehensive analyses on bioinformatics level on their structural diversity and specificity

across different Brassicaceae species limits our understanding of their evolutionary adaptations and molecular function (Stec, 2006).

Progresses in structural bioinformatics, largely driven by artificial intelligence and deep learning approaches, have revolutionized protein structure prediction and analysis. With the advent of bioinformatics methods, the near-experimental accuracy in predicting protein tertiary structures from amino acid sequences could be achieved, thereby accelerating structural studies at an unprecedented scale beyond the experimental paradigm (Jumper et al., 2021). This has opened the door to in-depth in silico studies of protein families with a focus on conserved structural motifs and residues required for function and to elucidate the potential impact of sequence variation on stability and activity (Huang, 2023).

Besides aiding in the prediction of protein structural classes, machine-learning algorithm integrations add more powerful data analysis tools for investigating sequence-to-structure relationships essential to explain molecular mechanisms of antimicrobial activity in thionins and other similar peptides (Zhu et al. 2021). Structural bioinformatics packages make possible detailed sequence and structure conservation analyses that further our ability to dissect functional determinants within protein families (Grant et al., 2021).

The work illustrates the contemporary interplay between structural bioinformatics and artificial intelligence in stimulating advances in plant molecular biology and protein engineering. The study's results provide useful information on thionin structural diversity and its evolution, pointing to a possible use of these proteins to develop novel antimicrobial strategies against phytopathogens.

MATERIALS AND METHODS

Thionin protein data received

In this research, the Thionin protein Reference Sequences (RefSeq) of different plant species were downloaded from NCBI (<http://www.ncbi.nlm.nih.gov>) in FASTA format (date received: November 2024). Due to the large number of sequences available for Thionin protein in plants, it is not possible to analyze all the sequences. Among the thioninplant sequences, those with the range of 115 to 134 amino acids were designated by the NCBI filters, and one sequence from each plant's genus was selected as their representatives for further analyses. Total data consisted of six plant species, which are listed in Table 1 with their families, orders, accession numbers, and abbreviations.

Table 1. The list of fourteen Thionin plant species analyzed in the current study

Index	Scientific Name	Family	Order	Abbreviation	Accession number
1	<i>Brassica napus</i>	Brassicaceae	Brassicales	<i>Bn</i>	XP_022561535
2	<i>Brassica rapa</i>	Brassicaceae	Brassicales	<i>Br</i>	XP_009134335
3	<i>Raphanus sativus</i>	Brassicaceae	Brassicales	<i>Rs</i>	XP_018462798
4	<i>Eutrema salsugineum</i>	Brassicaceae	Brassicales	<i>Es</i>	XP_006418673
5	<i>Capsella rubella</i>	Brassicaceae	Brassicales	<i>Cr</i>	XP_023633900
6	<i>Camelina sativa</i>	Brassicaceae	Brassicales	<i>Cs</i>	XP_019097238

Structural analyses

Several online web services and software were used for analyses of thionin in plants. Total number of amino acids, theoretical isoelectric point, instability index, aliphatic index, and grand average of hydropathicity (GRAVY) of plant samples were predicted by ProtParam (<http://web.expasy.org/protparam/>) (Gasteiger et al. 2005). Secondary structures were predicted by SOPMA server (http://npsa-pbil.ibcp.fr/cgi-bin/npsa_automat.pl?page=npsa_sopma.html) (Geourjon and Deleage 1995).

The tertiary structure prediction analysis of thionin protein families was predicted by Phyre2 server (<http://www.sbg.bio.ic.ac.uk/phyre2/html/page.cgi?id=index>) (Kelley and Sternberg 2009) using profile-profile matching and secondary structure in representative plant species. Chimera 1.11 was used for 3D structure modeling of *Raphanus sativus* as a sample of plant's species (<https://www.cgl.ucsf.edu/chimera/>). The 3D model of thionin protein was created using the “c1ed0A” model (PDB Accession Code: 1ed0) with 99.7% confidence level.

RESULTS AND DISCUSSION

In order to investigate the structures of thionins, six species from different Brassicaceae species were analyzed by bioinformatics tools. The primary structure of selected thionins was analyzed by ProtParam. This server computes various physico-chemical properties that can be deduced from a protein sequence, including the instability and aliphatic index, and grand average of hydropathicity (GRAVY) (Table 2). Thionin protein in all Brassicaceae species ranged from 115 to 135 amino acids in length. Also, the molecular weight was calculated at a range of 12196.93-14318.72Da.

Table 2. Primary structure of thionin protein in six plant species

Index	Sample	Number of amino acids	Molecular weight	Theoretical pI	Instability index	Aliphatic index	GRAVY
1	<i>Bn</i>	115	12196.93	5.55	48.77	78.09	0.070
2	<i>Br</i>	134	13972.09	7.40	25.09	81.57	0.138
3	<i>Rs</i>	133	13912.96	7.38	43.89	82.86	0.101
4	<i>Es</i>	133	14318.72	7.40	41.90	76.39	0.058
5	<i>Cr</i>	133	13781.90	5.36	29.37	79.92	0.111
6	<i>Cs</i>	135	14167.45	7.90	38.71	84.52	0.128

Isoelectric Point is the pH at which a protein carries no net charge. Below the isoelectric point proteins carry a net positive charge, and above it, a net negative charge. The isoelectric point is of significance in protein purification since it is the pH at which solubility is often minimal and at which mobility in an electrofocusing system is zero, and therefore the point at which the protein will accumulate (Seddigh, 2019). In computing PI analysis, the most isoelectric point in thionin of selected Brassicaceae species belonged to *Camelina sativa* (7.90), while the least was found in *Capsella rubella* (5.36). This analysis revealed that thionin proteins are different in nature and depend on the species, may be acidic or basic. In the current analysis, all the samples were basic except Bn and Cr, which showed acidic characteristics in nature. The aliphatic index of a protein is defined as the relative volume occupied by aliphatic side chains (alanine, valine, isoleucine, and leucine). The aliphatic index value of proteins from thermophilic bacteria was found to be significantly higher than that of ordinary proteins, and hence, it can serve as a measure of thermostability of proteins (Ikai, 1980). So, this is a positive indicator of globular protein thermostability. High aliphatic index in thionins indicated structural stability of this protein in plant samples.

The GRAVY value for a protein is calculated as the sum of hydropathy values of all the amino acids, divided by the number of residues in the sequence (Kyte and Doolittle, 1982). According to Kyte and Doolittle (1982), integral membrane proteins typically have higher GRAVY scores than do globular proteins. Though the GRAVY score is a helpful piece of information, it cannot reliably predict the structure without the help of hydropathy plots. Gravy index scores of proteins below 0 are more likely globular (hydrophilic protein), while scores above 0 are more probable membranous (hydrophobic protein). The GRAVY values of this protein, designated thionin Brassicaceae species to be membranous (hydrophobic protein) in nature.

The instability index is a measure of proteins, used to determine if they will be stable in a test tube or not. It is also known that an instability index less than 40 predicts a stable protein, while values higher than 40 denote a potentially unstable protein (Seddigh, 2019). The Instability index analysis of Brassicaceae thionin revealed that three of the representative plant samples, including *Brassica napus*, *Raphanus sativus*, and *Eutrema salsugineum* were unstable, and the rest of them were stable proteins.

The secondary structure of Brassicaceae thionin proteins was predicted by Self-Optimized Prediction Method with Alignment (SOPMA) server, which analyzes the percentage of alpha helix, extended strand, and random coil. The prediction of the secondary structure of thionin based on hierarchical neural network analysis (combet et al., 2000) revealed that the most plentiful structural elements of the secondary structure were alpha helices and random coils, while extended strands were occasionally distributed in the proteins. Also, there were just two exceptions among all samples, so that random coil structures were more than alpha helices, including *Brassica napus* and *Camelina sativa* (Table 3).

Table 3. Secondary structure of thionin protein in six plant species

Index	Sample	Alpha helix	Extended strand	Random coil
1	<i>Bn</i>	34.78	15.65	49.57
2	<i>Br</i>	49.25	8.21	42.54
3	<i>Rs</i>	45.86	9.77	44.36
4	<i>Es</i>	49.62	7.52	42.86
5	<i>Cr</i>	46.62	10.53	42.86
6	<i>Cs</i>	44.44	8.89	46.67

The key objective of protein structure prediction is the tertiary structural modeling, which is crucial for a full understanding of protein function. Also, structures are much more conserved than sequences, so their evaluations allow us to look even further back into biological prehistory (Orengo et al., 2003; Seddigh, 2019). So, three-dimensional modeling of six Brassicaceae samples was predicted by Phyre2. This server uses profile–profile matching and secondary structure for tertiary structure prediction (Kelley et al., 2015) and uses the alignment of hidden Markov models through HHsearch (Söding, 2005). Based on these analyses, the tertiary structure of these plant thionin proteins was very similar to each other, which confirmed the conserved structure of this protein (Figure 1).

Figure 1. Tertiary structure of thionin protein in *Raphanus sativus* as the Brassicaceae representative sample (PDB accession code: 5szn) using Phyre2 server. (a) Ribbons model, alpha helices are shown with helix shape and beta sheets with arrows. (b) Hydrophobicity surface model using Chimera 1.11. Color from red for negative potential, to blue for positive potential.

SUSTAINABLE TOURISM IN TÜRKİYE AND THE BALKAN COUNTRIES: POLICY EVOLUTION AND KEY CHALLENGES

Mehmet Emin Baynazoğlu

*Trakya University Keşan Yusuf Çapraz College of Applied Sciences, Department of
Management Information Systems, Kesan, Türkiye*

meminbaynazoglu@trakya.edu.tr

ABSTRACT

This study examines the development process of sustainable tourism policies implemented in Türkiye and the Balkan countries, along with the key challenges encountered, through a comparative approach. The historical development of the concept of tourism and the policies developed in line with sustainability principles are evaluated in terms of the economic, social, and environmental dimensions of current tourism activities in Türkiye and the Balkan countries. The study analyzes theoretical and practical aspects using secondary sources published between 2010 and 2025. The Balkan countries and Türkiye, sharing a close geographical proximity and common history, possess cultural, natural, historical, and geographical characteristics. With all these features and sustainable tourism practices, the Balkan countries have become a center of attraction for visitors from various countries around the world, particularly Türkiye. However, the wars and internal conflicts experienced in the recent history of the Balkan countries, management crises, and ongoing infrastructure and superstructure issues in certain regions hinder the substantial increase of tourism revenues. This situation continues to obstruct the sustainability of tourism in the region. The study highlights the importance of regional cooperation and the strategic objectives established by the European Union in developing sustainable tourism policies. Through a detailed comparison between Türkiye and the Balkan countries, this evaluation assesses the current state of sustainable tourism policies and proposes solutions to potential obstacles and issues. As a result of this research, it has been observed that sustainable tourism policies are generally determined by central authorities, with limited public participation in this process. The most significant barriers to achieving sustainable tourism goals have been identified as a lack of long-term planning, weak evaluation mechanisms, insufficient local capacity, and gaps in coordination among stakeholders. According to the findings obtained from the research, sustainable tourism policies in the Balkan countries are generally developed in accordance with their EU membership processes. Despite the pursuit of EU-compatible policies, bureaucratic obstacles are encountered in accessing the budget required for the implementation of these policies. Moreover, it is observed that decisions concerning policy-making are taken by central authorities. This research provides suggestions and recommendations to policymakers, researchers who will conduct studies on this topic, and all individuals and institutions concerned about sustainable tourism in Türkiye and the Balkan countries.

Keywords: Tourism Enterprises, Sustainable Tourism, Tourism Policy.

1. INTRODUCTION

Tourism is one of the sectors that has the highest potential for job creation and generating foreign income in the world (Alam et al., 2022). Due to these characteristics, the tourism industry makes significant contributions to regional economic development, intercultural

communication, and optimal resource utilization. For all these stated activities to continue to take place in the long term, there is a necessity for tourism practices to be sustainable. In sustainable tourism practices, efforts are expected to be made to ensure the protection of resources such as the natural, historical, and cultural heritage that countries possess.

Türkiye and the Balkan countries, due to their closely located geographical regions, offer highly attractive prospects for visitors seeking sustainable tourism practices. On the other hand, the institutional capacities, sustainable tourism policies, and regional cooperation ideas of Türkiye and the Balkan countries, which are geographically and culturally so close to each other, exhibit significant differences (İşgüven and Şeker, 2024). Among the Balkan countries, Serbia, Albania, Montenegro, Bosnia and Herzegovina, Kosovo, and North Macedonia, which are not yet EU members, are striving to align their national tourism policies on sustainable tourism with the strategies of the European Union, similar to the EU member states of Bulgaria, Greece, Romania, Slovenia, and Croatia. Although the membership processes and funding for these non-EU Balkan countries have accelerated regional initiatives, it has been observed that several obstacles and limitations persist (Kamberi & Shkreli, 2023).

2. METHODOLOGY

This study was conducted using a review method mainly based on academic articles, policy documents, official reports, and sectoral analyses published between 2015 and 2025. Within the scope of the research, the development process of sustainable tourism policies has been examined through a comparative approach, focusing on both Türkiye and the Balkan countries. The literature review was carried out using international databases such as Web of Science, Scopus, and Google Scholar; the selected sources were evaluated in terms of their compliance with sustainability principles across economic, social, and environmental dimensions. Additionally, European Union strategy documents and regional development plans were included in the analysis process to elaborate on policy orientations and implementation challenges. Throughout the research process, the determining factors of sustainable tourism policies, implementation barriers, and regional differences were identified through comparative analysis.

In the research process, the determinants of sustainable tourism policies, implementation barriers, and regional differences have been revealed through a comparative analysis method. Considering the structural, historical, and administrative differences between Türkiye and the Balkan countries, a comprehensive evaluation has been conducted through policy documents and academic studies. This method has brought together both theoretical and practical perspectives; the current situation of sustainable tourism and future recommendations have been presented within a holistic framework.

2.1. The Development of Sustainable Tourism Policies in the Balkan Countries

The Western Balkan countries are noted for their rich cultural history, which includes historical artifacts and areas, traditional crafts, and unique customs and traditions. Sustainable tourism helps to preserve this heritage by promoting the introduction and safeguarding of cultural values among visitors. Furthermore, sustainable tourism is regarded as promoting social inclusion and respect for diversity. It encourages cultural connection and mutual exchange between visitors to sustainable tourism sites and the local inhabitants. This also helps to break down boundaries between different cultures and communities, improving mutual understanding (Mulita, 2024). Sustainable tourism is considered to be the key to the success of tourism destinations, and in this context, Bosnia and Herzegovina, one of the Balkan countries, has been making intense efforts in recent years to develop sustainable selective tourism through various collaborations,

initiatives, and organizations. Given that tourism relies on the cooperation between numerous sectors, it is essential to involve tourism businesses from the private sector, public and civil society organizations, consumers, development agencies, and local communities in the process to ensure the success of the destination (Pobrić & Osmanović, 2024).

In the 1980s, the increasing global awareness of environmental issues and the concept of sustainable development contributed to the emergence of sustainable tourism. The Brundtland Report, prepared in 1987, defines sustainable development as 'meeting the needs of the present without compromising the ability of future generations to meet their own needs' (United Nations, 1987). This understanding necessitates the simultaneous consideration of economic, environmental, and social dimensions in tourism planning. Sustainable tourism practices worldwide have diversified through the implementation of environmental management systems, eco-certifications, programs that promote the participation of local communities, and responsible tourism initiatives. In Europe, many countries have implemented sustainable tourism policies at both national and regional levels that prioritize the preservation of natural and cultural heritage. (Serio, Dickson, de Graaff & Pels, 2024).

Tourism began as an activity solely aimed at rest and recreation throughout history, evolving over time into a comprehensive sector with economic, social, and cultural dimensions. In the early 20th century, tourism was primarily focused on economic gain and recreation; however, the rapid and unregulated growth of the sector has also led to negative consequences such as environmental degradation, erosion of cultural values, and socio-economic imbalances (Mihalic, 2016; Hall, C. M., Gössling, S., & Scott, 2015). These phenomena have laid the groundwork for the development of sustainable tourism.

2.2. Challenges Encountered in Sustainable Tourism Policies in the Balkan Countries

Europe, one of the continents with the largest share in global tourism revenues and mobility, possesses considerable tourism potential within the Balkan geography, enriched by its rich cultural and natural heritage. However, the countries in the region face specific challenges unique to their respective nations in implementing sustainable tourism policies and aligning with European Union standards in this region.

First, deficiencies and inadequacies in institutional capacity and governance are among the prominent issues. The EU plays a role in coordinating, guiding, and shaping the national policies of member states within the framework of sustainability principles (Yıldırım and Keleş, 2022). Both Balkan countries that are EU members and those that are candidates for EU membership struggle to ensure effective coordination between central and local governments. For instance, in EU member states as Romania and Bulgaria, bureaucratic obstacles and inadequate transparency in the distribution and oversight of resources allocated for EU funds and sustainable tourism projects complicate the effective implementation of policies on the ground.

Another significant challenge related to the Balkan countries is the inconsistencies in legislation and the problems encountered in implementation. The EU's policy areas, such as Environment, Transport, and Regional Development, indirectly influence sustainable tourism (Gürsoy, 2017; Yıldırım and Keleş, 2022). In coastal regions, intense construction and environmental pollution contradict the principle of natural resource conservation and undermine the goals of sustainable development. For instance, the excessive tourism pressure experienced on Greece's Santorini Island and in Croatia's Dubrovnik city strains the infrastructure and leads to a deterioration in the quality of life for the local population and the environmental balance (Çam & Çelik, 2022).

Sustainable tourism practices (such as energy efficiency and waste management systems, etc.) often require a high initial investment cost. According to TÜSİAD's Sustainable Tourism Report (2012), it is known that businesses lack the financial resources or technical knowledge necessary to undertake this transformation due to their short-term profit-oriented perspective. It can be observed that the Balkan countries pursue distinct campaigns and strategies for their national tourism promotions (Porfido, 2020);

Table 1: Tourism Policies and Promotion Campaigns of Balkan Countries. (Porfido, 2020)

Country	Recent Tourism Strategies and Policies	Recent Tourism Promotion Campaign
Albania	Sustainable Tourism Development Strategy 2019–2023 (Ministry of Tourism and Environment, 2019)	Albania – Go your own way
Bosnia and Herzegovina	Tourism Development Strategy for the Federation of Bosnia and Herzegovina 2008–2018 and Republika Srpska Tourism Development Strategy 2010–2020 (OECD, 2018)	Bosnia & Herzegovina – The heart-shaped land
Croatia	Tourism Development Strategy of Croatia until 2020 (Government of Croatia, 2013)	Croatia – Full of life
Kosovo	No officially approved or drafted national tourism strategy	Be in Kosovo – the young Europeans (unofficial)
Montenegro	Tourism Development Strategy of Montenegro until 2020 (Ministry of Tourism and Environment, 2008)	Montenegro – Wild beauty
North Macedonia	National Tourism Development Strategy 2016–2021 (Government of North Macedonia, 2016) – only in draft form	Macedonia Timeless
Serbia	Tourism Development Strategy of Serbia 2016–2025 (Government of Serbia, 2016)	Serbia - The place to be

As can be seen in the table above, tourism promotion and marketing activities in the Balkan countries are still focused on mass tourism movements. Areas related to niche and sustainable tourism, such as cultural, ecological, or rural tourism, are not being effectively promoted and marketed. In the context of the relationship between foreign policy and tourism, the bilateral agreements made (Aydemir and Çözeli, 2016) primarily focus on increasing visa facilitation and transportation connections, while the promotion of sustainable tourism products remains a secondary concern. This situation also hinders the increase in revenue that the Balkan countries could generate from sustainable tourism.

The Balkan countries are adopting the EU's sustainable tourism narrative and policies. However, during the implementation phase of these policies, they face serious challenges regarding institutional capacity, effective legislation enforcement, access to financing, and marketing strategies. Overcoming these challenges will only be possible through strong political will, effective participation of all stakeholders in the sustainable tourism process, and ensuring the purposeful and transparent use of EU funds.

2.3. The Development of Sustainable Tourism Policies in Türkiye

After the COVID-19 pandemic, which affected all sectors worldwide, Türkiye prioritized sustainability in its tourism sector and entered a comprehensive restructuring process in its tourism policies. The Ministry of Culture and Tourism has identified sustainable tourism as a

strategic priority in the Updated Tourism Master Plan for the period of 2022–2024; through initiatives such as the 'Safe Tourism Certification,' it has facilitated the integration of COVID-19 safety practices into the tourism process, thereby strengthening certification and hygiene standards within the sector (OECD, 2022). During the same period, the Turkish Tourism Promotion and Development Agency (TGA) developed the 'National Sustainable Tourism Program' in collaboration with the Global Sustainable Tourism Council (GSTC) to align Türkiye's tourism sector with international sustainability criteria. Thus, Türkiye has gained a significant position in international sustainability efforts (Bergen, 2022).

Türkiye was included in the 'Green Travel List' of Wanderlust magazine in 2025, thereby starting to become more prominent in international ecotourism. A notable example of this recognition is the emphasis placed on Mount Nemrut, which is listed as a UNESCO World Heritage Site and highlighted in Wanderlust. With its monumental stone sculptures and ancient hill tombs, Mount Nemrut not only possesses extraordinary cultural and historical value but also demonstrates Türkiye's increasing commitment to the integration of ecologically conscious principles in heritage site management and sustainable tourism practices. (Sarkar,2025).

2.4. Challenges in the Implementation of Sustainable Tourism Policies in Türkiye

Although Türkiye has a strong potential for sustainability, there are several challenges that hinder the implementation of sustainable tourism policies. Foremost among these is environmental sustainability: poor management of natural resources, deficiencies in waste control, and environmental pollution remain major issues within the tourism sector. Furthermore, in some regions, infrastructure and transportation services are insufficient to accommodate tourist density. This inadequacy can negatively affect visitor experiences, leading to dissatisfaction. **Greenwashing practices presented as sustainability:** The prevalence of greenwashing practices in the tourism sector raises questions about the industry's credibility. For instance, hotels boasting about sustainability by producing only 10 kilograms of cucumbers annually in their gardens illustrate how the industry often misunderstands the concept of sustainability. Collectively, these challenges represent significant obstacles to Türkiye's sustainable tourism vision (Akgül, 2024)

Although efforts towards sustainable tourism opportunities in Türkiye are intense, issues such as inadequate infrastructure, lack of coordination, and the absence of policies based on long-term planning remain primary concerns. For instance, excessive development in many coastal destinations and the unconscious use of natural resources jeopardize sustainability; these problems result in even more negative outcomes due to short-term profit-oriented approaches that harm the environment. Furthermore, the inability of non-governmental organizations, local communities, and other stakeholders directly affected by the policy to participate in the formulation process of sustainable tourism policies poses a significant issue. Additionally, the lack of coordination between the central government and local authorities represents another barrier to implementing sustainable tourism policies.

3. CONCLUSION AND DISCUSSION

This study provides a detailed analysis and comparison of sustainable tourism practices in Türkiye and the Balkan countries, addressing the barriers and challenges that arise during policy implementation. Both Türkiye and the Balkan countries share similar geographical features, as well as a common history and cultural heritage. Moreover, given their natural characteristics, both regions possess significant potential for sustainable tourism. Despite their high potential

for sustainable tourism practices, Türkiye and the Balkan countries converge on certain issues while diverging on others during the policy implementation process.

The adoption of sustainable tourism practices in Balkan countries can offer several advantages to stakeholders involved in these initiatives. While enhancing the resilience of destinations and businesses, it will positively impact local stakeholders' access to all public services. Some of the advantages that sustainable tourism can provide to its stakeholders include: being prepared for future adversities, becoming resilient in challenging conditions, attracting interest from domestic and foreign investments, reducing negative environmental impacts and rehabilitating affected areas, lowering operational costs, promoting the development of local regions, creating quality jobs and learning opportunities for local communities, meeting changing consumer demands, raising awareness among visitors and potentially altering their behavior, and offering individual and unique experiences to regional visitors, among others. Some of the issues encountered regarding sustainable tourism practices in the Balkan countries are as follows: deficiencies in infrastructure, political instability, legal regulations and legislative issues, the degradation of ecosystems due to sustainable tourism, over tourism, pressure on physical infrastructure (for example, excessive utilization of waste management systems, public transportation, traffic congestion, etc.), rapidly rising living costs or insufficient housing, and the intensive use issues concerning regional resources such as water, electricity, and food (Chavez et al. 2023).

Decision-makers in the Western Balkan countries should consider the following aspects while formulating tourism policies;

EU Compliance Requirement: Initiatives such as the EU's Green Deal and New Generation EU, which are the main markets and economic partners, directly influence regional policies.

Need for Transformation: Green and digital transformation, carbon neutrality targets, and circular economy models are no longer an option but a necessity.

Changing Demand: Tourists are now seeking sustainable, authentic, and technology-infused experiences, which necessitate tourism diversity.

Regional Cooperation: Despite historical issues, a 'Western Balkans' brand created through cooperation instead of competition will provide a much stronger positioning in the global market (Knežević et al., 2024).

The Balkan countries need to create a new strategic roadmap that will adapt to current market dynamics and center around sustainable tourism principles. In this context, increasing the diversity of existing tourism products (Porfido, 2020) and spreading tourism investments to new destinations to balance regional development are among the primary goals.

The COVID-19 pandemic, which has profoundly affected all sectors around the world, particularly the tourism industry, has changed the way business is conducted globally. Following the pandemic, sustainable tourism has gained substantial importance in Türkiye's tourism sector and has begun to be prioritized by businesses and managers. Programs such as the "Safe Tourism Certificate" and the "National Sustainable Tourism Program" developed in collaboration with the Global Sustainable Tourism Council have opened a significant new chapter in the tourism sector, with hotel businesses making intensive efforts to stay ahead of their competitors. For instance, prominent enterprises in Turkish hospitality, such as Hilton Istanbul Bosphorus and Conrad Istanbul Bosphorus Hotels, are reusing 120 tons of water in one day through a greywater system to obtain sustainability certifications issued by the Global Sustainable Tourism Council, and they are implementing effective waste management, aiming to reduce their carbon footprint by 50% by the year 2030 (Turizm Proje Dergisi, 2023).

Proposals for the development of sustainable tourism policies in Türkiye:

Environmental Sustainability and Management of Existing Natural Resources

- Increased utilization of green technology practices for waste management and energy conservation.
- Tourism planning in accordance with the carrying capacities of natural areas.
- Promotion of renewable energy use in tourism businesses.

Ensuring Community Participation

- Ensuring the active involvement of local communities in the decision-making processes related to sustainable tourism practices.
- Increasing local economic benefits and enhancing points of sale for local products.
- Raising public awareness regarding sustainable tourism practices through education and seminars.

Improving Infrastructure and Sustainable Solutions in Individual and Public Transport

- Development of environmentally friendly transportation systems, such as bike paths and electric public transport in tourism regions.
- Planning sustainable infrastructure investments for access to cultural and natural heritage areas

Development of Policy and Legal Framework

- Making environmental certification systems mandatory for all tourism businesses
 - Enhancing inspection and enforcement mechanisms. Education and Capacity Development
 - Programming sustainability-focused training for employees in businesses operating within the tourism industry.
 - Incorporating lessons on climate change, green economy, and sustainability into school curricula at all educational levels, from primary school to university.
- #### International Cooperation and Effective Resource Utilization
- Effectively utilizing sustainable tourism projects and grants supported by the EU and UN
 - Strengthening regional cooperation by developing joint destination packages with Balkan countries.

AGBIOL 2025 CONFERENCE STUDENT ORGANIZING TEAM

NAME

1. Emrah Akpınar
2. Deniz Kızılkaya
3. Mutlu Şen
4. Selinay Demir
5. Neslihan Yılmaz
6. Begüm Kurt
7. Serhat Kayan
8. Hilal Aydın
9. Elif Sena Köksal
10. Bilge Irmak Özdiñ
11. Öyküm Vural
12. Serhat Parlak
13. Cihan Mert Aktaş
14. Efe Tanrıverdi
15. Nihan Güleş
16. İdal Karayel
17. Neval Gedik
18. Tuğçe Arıcı
19. Neslihan Ocakçı
20. Ahmet Yusuf Pakkan
21. Defnesu Çapas
22. Busenur Hilal Akpınar
