WELCOME NOTES

You are welcome to our VII. AGBIOL Conference that is organized by Trakya University, Beykent University and International Researchers Association. The aim of our conference is to present scientific subjects of a broad interest to the scientific community, by providing an opportunity to present their work as oral or poster presentations that can be of great value for global science arena. Our goal was to bring three communities, namely science, research and private investment together in a friendly environment of Edirne, Turkey in order to share their interests and ideas and to get benefit from the interaction with each other.

In September 2018, we organized the first AGBIOL Conference with more than 700 scientists and researchers from all over the world with over 800 scientific papers. Due to COVID-19 situation, II. AGBIOL 2020 has organized fully on-line event which was one of the biggest online conferences in recent years in the world with 499 papers and 1133 authors with 333 oral and 166 e-poster presentations from 55 countries. Due to COVID-19 situation, AGBIOL 2021 was organized online again. AGBIOL 2022 conference was organized with a worldwide participation from 44 countries over 522 papers contributed by over 1300 authors. AGBIOL 2023 was organized with a record and worldwide participation from 33 countries 833 papers contributed by over 2000 authors with 522 oral and 311 poster presentations. AGBIOL 2024 consisted of 835 papers contributed by about 2000 authors with worldwide record participation again from 55 countries with 522 oral and 311 poster presentations.

There is a worldwide record participation from 60 countries 988 papers contributed over 2300 authors with 400 oral and 588 poster presentations in AGBIOL 2025.

The AGBIOL 2025 is normal participation as well as with online participation in Beykent University in Istanbul, Turkey on 07-10 September, 2025. The program included oral talks by invited prominent scientists and oral and e poster presentations by participants in selected topics from the submitted abstracts focusing on Agriculture, Biology and Life Sciences topics.

With care for our nature and environment, we aim the green congress, meaning that as little as possible papers will be used. Abstract book is published in electronic book and is distributed to the participants by e mail for online participants. All the e-posters are prepared in electronic form and then submit to via the conference e mail and exhibited in electronical poster boards as well as in online e poster hall in our web page during the conference.

The participants with paid conference fee accessed all the normal and virtual presentation talks in each session, as well as to visit the virtual poster hall via preliminary provided. The abstracts were published in the Conference Abstract and Proceedings Book. Participants might send us their full papers, which based on their preferences are published either in our Conference Abstract and Proceedings Book or in selected International Indexed Scientific Journals.

Conference Topics:

Agriculture, Forestry, Life Sciences, Agricultural Engineering, Aquaculture and Biosystems, Animal Science, Biomedical science, Biochemistry and Molecular Biology, Biology, Bioengineering, Biomaterials, Biomechanics, Biophysics, Bioscience, Biotechnology, Botany, Chemistry, Chemical Engineering, Earth Sciences, Environmental Science, Food Science, Genetics and Human Genetics, Medical Science, Machinery, Pharmaceutical Sciences, Physics, Soil Science.

We would like to thank all of you for joining this conference and we would like to give also special thanks to TUBITAK and collaborators for giving us a big support to organize this event.

Prof Dr Yalcin KAYA

Head of the Organizing Committee

ORGANIZING COMMITTEE

<u>NAME</u>	<u>INSTITUTION</u>	<u>COUNTRY</u>
Prof. Dr. Volkan ONGEL	Rector of Istanbul Beykent Univ, Türkiye	Honorary President
Prof. Dr. Mustafa HATIPLER	Rector of Trakya Univ, Türkiye	Honorary President
Prof. Dr. Yalcin KAYA	Trakya University, International Researcher Assoc (IRSA), Türkiye	Chair
Prof. Dr. Bahaddin SINSOYSAL	Istanbul Beykent Univ, Türkiye	Co & Host Chair
Assoc Prof. Dr. Necmi BEŞER	Tragen Ltd Şti, Trakya University Technopark, Türkiye	Co-Chair
Emrah AKPINAR	Trakya University, Türkiye	Secretary
Asst. Prof Dr. Hasan BOZTOPRAK	Istanbul Beykent Univ, Türkiye	Member
Prof. Dr. Vilianna VASSILEVA	Maize Res Inst-Knezha, Bulgaria	Member
Prof. Dr. Ioannis TOKATLIDIS	Trakia Democritus Univ, Greece	Member
Prof Dr Metin TUNA	Tekirdag Namik Kemal Univ, Türkiye	Member
Asst Prof Dr Orhan ASKIN	Kırklareli University, Türkiye	Member

SCIENTIFIC COMMITTEE	6
EFFECT OF IRON FOUNDRY DUST ON THE ENERGY EFFICIENCY OF HYDROPHILIC NANOCOATED PHOTOVOLTAIC PANELS	16
TECHNICAL AND ECONOMIC ANALYSIS OF THE SOLAR ENERGY SYSTEM DESIGNED FOR EDİRNE PROVINCE AGRICULTURAL RESEARCH INSTITUTE BUILDING IN THE CASE OF ROOF AND FACADE APPLICATION	25
IMPACT OF REGULAR WATER-BASED CLEANING ON THE ENERGY EFFICIENCY OF PHOTOVOLTAIC PANELS	31
QUANTUM-CHEMICAL STUDY OF NOVEL MULTIFUNCTIONAL POLYMER BY SUBSTITUTION REACTION OF GRAFTING ACETYLSALICYLIC ACID.....	38
ASSESSMENT OF THE TRANSITION FROM CONVENTIONAL SOIL TILLAGE TO MINIMUM TILLAGE TECHNOLOGY IN A MAIZE CROP WITH THREE HYBRIDS – A THREE-YEAR CASE STUDY IN LANURILE, CONSTANȚA COUNTY	45
INNOVATIVE AGRICULTURE THROUGH RECYCLING: SUSTAINABLE BIOLOGICAL PRODUCTION SYSTEMS FROM DISCARDED MATERIALS	58
SOME TAXONOMIC, ECOLOGICAL AND ETHNO-ENTOMOLOGICAL DATA ON THE LOCUSTS (ORTHOPTERA) OF THE HABITATS OF VLORA.....	72
DAIRY SECTOR VALUE CHAINS IN BOSNIA AND HERZEGOVINA	81
ANTISTAPHYLOCOCCAL STUDY OF THE ESSENTIAL OIL OF MENTHA PULEGIUM L. FROM ALGERIA	92
THE HOME GARDENS AS BIOCULTURAL RESERVE OF LOCAL PLANT DIVERSITY AND TRADITIONAL KNOWLEDGE.....	98
STATIC ANALYSIS OF FUNCTIONALLY GRADED POROUS SANDWICH BEAMS.....	107
INVESTIGATION OF THE EQUIVALENT MECHANICAL PROPERTIES OF TPMS LATTICE STRUCTURES	121
PRODUCTION AND CHARACTERIZATION OF MESOPOROUS ACTIVATED CARBON FROM CAROB TREE BIOMASS FOR ENVIRONMENTAL APPLICATIONS	138
BOLTING IN SPINACH; GENETIC AND ENVIRONMENTAL FACTORS	146
POSSIBLE MORPHOLOGICAL EVIDENCES FOR A NEW SPECIES OF <i>EUPALOPSELLUS</i> (ACARIFORMES: EUPALOPSELLIDAE): INSIGHTS FROM A FEMALE SPECIMEN COLLECTED FROM TÜRKİYE.....	161
GIS MAPPING OF SOIL MACRONUTRIENTS FOR NUTRIENT MANAGEMENT IN HAZELNUT	166
CLASSIFICATION OF CURRENT ARTIFICIAL INTELLIGENCE APPLICATIONS ACCORDING TO THEIR FUNCTIONALITY	172
EFFECTS OF CHEMICAL AND ORGANOMINERAL FERTILIZERS ON MORPHOLOGICAL CHARACTERISTICS AND YIELD.....	186

BALANCE, BACTERIA, AND THE BLACK BELT: IMPACT OF PROBIOTICS ON GASTROINTESTINAL SYMPTOMS DURING JUDO TRAINING AND JUDO COMPETITIONS	192
BIOSURFACTANT POTENTIAL OF PROBIOTIC MICROORGANISMS ISOLATED FROM FERMENTED CABBAGE: A SUSTAINABLE APPROACH TO FUNCTIONAL BIOPRODUCTS.....	201
HEAT AND COLD STRESS IN WATER BUFFALOES (BUBALUS BUBALIS): A REVIEW	212
AN OBSERVATION ON AN ANOMALY IN THE SCE SETA DISRUPTING BILATERAL SYMMETRY IN <i>TYCHEROBIUS IZMIRENSIS</i> AKYOL & KOÇ (ACARIFORMES: CAMEROBIIDAE)	218
SPATIOTEMPORAL PATTERNS OF TRACE ELEMENTS (LI, MN, NI, BA) IN RIVERS FEEDING THE İSTANBUL STRAIT, TÜRKİYE.....	227
PHYSIOLOGICAL EFFECTS OF LOW AND HIGH TEMPERATURE STRESS ON CORN WITH MYCORRHIZAL SYMBIOSIS	232
PROBABILISTIC ASSESSMENT OF FLUORIDE-RELATED HEALTH RISKS IN GROUNDWATER OF THE FELENT STREAM WATERSHED, KÜTAHYA.....	243
SPATIAL-TEMPORAL VARIATIONS OF FLUORIDE IN SURFACE WATERS OF FELENT STREAM (TÜRKİYE) AND ASSOCIATED HEALTH RISKS.....	250
ENVIRONMENTAL IMPACTS OF GREENHOUSE GAS EMISSIONS AND PROPOSED SOLUTIONS FOR THEIR REDUCTION	257
FROM SOIL TO SURVIVAL: PGPB-TRIGGERED DEFENSE AND ADAPTATION IN PLANTS	266
TOXIC DIALOGUES: HERBICIDES, MICROBIAL VOICES, AND THE ECOSYSTEM'S RESPONSE.....	281
THE IMPORTANCE OF MARKER ASSISTED SELECTION IN BLACKBERRY	292
SOFT CHEMISTRY NANOCOMPOSITE OF MGO DOPED PVC FABRICATION FOR PHOTOCATALYTIC APPLICATIONS	300
VALORIZATION OF FOOD INDUSTRY WASTES FROM CEREALS AND PULSES INTO FUNCTIONAL FOOD ADDITIVES	314
THE ROLE OF ORGANIC FERTILIZER ON CROP PRODUCTION IN AFGOI-SOMALIA	323
INTERVAL VALUED PYTHAGOREAN FUZZY AHP-INTERVAL VALUED PYTHAGOREAN FUZZY TOPSIS METHOD FOR SOLAR POWER PLANT SITE DECISION	332
LEGAL ISSUES FACED BY FARMERS AND AWARENESS OF AGRICULTURAL LAW IN THE TRAKYA REGION	340
MOLECULAR MARKER-BASED APPROACHES IN DETERMINING ALMOND GENETIC DIVERSITY: A REVIEW OF RECENT STUDIES.....	350
THE EFFECTS OF GLOBAL WARMING ON THE WATER QUALITY OF LAKES AND RIVERS.....	358
CHLORINE CONTAMINATION IN DILUTE NITRIC ACID PRODUCTION: SOURCES, EFFECTS, AND PREVENTION METHODS	365

SHORT-TERM EFFECTS OF DIFFERENT ORGANIC FERTILIZERS ON SOIL CHEMICAL PROPERTIES AND PLANT GROWTH IN MELON AND WATERMELON CULTIVATION	371
IDENTIFICATION OF SNP MARKERS ASSOCIATED WITH GENES CONTROLLING POTASSIUM AND SODIUM CONCENTRATION IN WALNUT FRUIT BY GWAS METHOD	382
PROPOLIS AGAINST <i>BOTRYTIS CINEREA</i> : A REVIEW OF STUDIES COMBINING IN VITRO AND IN VIVO TESTS.....	394
BIOCONTROL ACTIVITY OF <i>Trichoderma harzianum</i> AGAINST <i>Fusarium culmorum</i> CAUSING ROOT AND CROWN ROT IN WHEAT UNDER SALT STRESS CONDITIONS	402
POLY(4,4"-BIS(2'-FLUORENYLIDENEIMINO)-3,3"-DIMETHYLBIPHENYL): ELECTROSYNTHESIS, CHARACTERIZATION AND APPLICATION IN ORGANIC PHOTOVOLTAIC CELL	410
ASSESSMENT OF RIPARIAN VASCULAR FLORA OF THE RIVER SHKUMBIN NEAR ELBASAN AREA, ALBANIA	416
HORTICULTURAL PRACTICES IN POT CULTIVATION OF RHODODENDRON SPECIES: A CASE FROM TURKEY	423
EVALUATION OF THE ANTIOXIDANT ACTIVITY OF DAUCUS CAROTA L. ESSENTIAL OIL FROM EL-TAREF -ALGERIA	432
RECENT ADVANCES IN ALMOND MICROPROPAGATION AND FUTURE PERSPECTIVES.....	438
ASSESSING THE IMPACT OF GLOBAL WARMING ON SOIL HEALTH AND AGRICULTURAL PRODUCTIVITY.....	447
PRE-TREATMENT WITH GILABURU EXTRACT ALLEVIATES H ₂ O ₂ -INDUCED CYTOTOXICITY IN ENDOTHELIAL CELLS	466
A PRELIMINARY ANALYSIS OF FUNCTIONAL TRAIT COMPOSITION IN ADRIATIC SEA FISHERIES.....	471
SHORT-TERM EFFECTS OF DIFFERENT ORGANIC FERTILIZERS ON SOIL CHEMICAL PROPERTIES AND PLANT GROWTH IN MELON AND WATERMELON CULTIVATION	478
SMART BIOPOLYMER-BASED PACKAGING SYSTEMS AND CURRENT APPLICATIONS IN FOOD QUALITY TRACEABILITY.....	488
ENHANCING ENERGY EFFICIENCY IN AGRICULTURAL PRACTICES	508
APPLICATION OF LIPOSOMAL ENCAPSULATED ANTIMICROBIAL BIOACTIVE COMPONENTS IN FOOD PRODUCTS AS NATURAL PRESERVATION.....	512
REASONS FOR THE UNDERDEVELOPMENT OF CANOLA IN TÜRKİYE	519
ANTI-NUTRITIONAL SUBSTANCES CONTAINED IN RAPESEED.....	525
DETERMINATION OF THE STABILITY OF POLYPHENOL OXIDASE FROM BLACK MULBERRY TOWARDS DIFFERENT ORGANIC SOLVENTS AND SURFACTANTS	535
BIOCHEMICAL AND AROMATIC CHANGES IN PERSIMMON (<i>DIOSPYROS KAKI</i> L.) FRUITS HARVESTED IN DIFFERENT PERIODS	541
EFFECTS OF AQUAFABA AS ALTERNATIVE PLANT ADDITIVE ON PHYSICAL, TEXTURAL AND SENSORY CHARACTERISTICS OF EGGLESS TURKISH PASTA (ERİŞTE).....	556

ABSTRACT

In this study, the impact of dust accumulation an important factor affecting the efficiency of photovoltaic (PV) panels on energy production was experimentally investigated, with a specific focus on hydrophilic nanocoating and iron foundry dust. Two equivalent 100W PV panels were installed on the campus of the Faculty of Engineering at Trakya University. One of the panels (PV Panel A) was treated with a hydrophilic nanocoating, while the other panel (PV Panel B) was left untreated in its standard state. The experimental study was conducted over a five-week period from April 22 to May 27, 2025. During this time, the energy output of both PV panels was continuously recorded. According to the analysis of the experimental results, the total energy production of the hydrophilic nanocoated PV Panel A was measured as 13,485.6 Wh, whereas the standard PV Panel B produced a total of 10,197.0 Wh. It was observed that PV Panel A, with the hydrophilic nanocoating, generated 3,288.6 Wh (32.3%) more energy than PV Panel B during the test period. At the conclusion of the study, energy production graphs for both PV panels were plotted, and relevant analyses were presented.

Keywords: Energy, Photovoltaic Panel, Hydrophilic Nanocoating, Iron Foundry Dust

INTRODUCTION

In recent years, due to climate change, energy crises, economic concerns, and environmental issues, there has been a significant shift toward renewable energy sources for electricity generation. With technological advancements and the continuously growing global population, the demand for energy is increasing rapidly. Among alternative energy solutions to conventional sources such as oil, coal, and nuclear power, solar energy stands out as a promising option for the future. However, not all of the solar radiation reaching the Earth can be utilized for electricity generation through photovoltaic (PV) panels. Incoming solar radiation, which spans a wide spectrum, is divided into direct, diffuse, and reflected components due to atmospheric interactions. Approximately 30% of this radiation is reflected back by the atmosphere. Even under completely clear skies, only about 80% of the incoming radiation reaches the Earth's surface. On average, only about 50% of solar radiation is usable under normal daily conditions [1]. Several factors affect the efficiency of converting solar radiation into electrical energy through the photovoltaic effect. These include the inability of solar cells to fully absorb the radiation, the partial usability of photon energy, increased cell temperature, shading effects on the modules, and surface contamination of the module cells [1]. These

efficiency-reducing factors have long been the subject of extensive research, and alternative solutions continue to be sought. One of the key issues is dust accumulation on the PV panel surface and the resulting degradation of cell performance [2]. The reduction in energy efficiency of PV panels varies depending on the amount and type of dust accumulated on their surfaces. While many studies have focused on the general performance impact of dust on PV panels, relatively few have examined how different types of dust affect performance [2]. The extent of dust pollution varies significantly depending on the geographic location where solar energy systems are installed [3]. A variety of pollutants from different sources are encountered in urban and rural environments. For instance, particles such as limestone, ash, soil, sand, and general dust are transported differently depending on the region [4–5]. Additionally, dust accumulation becomes a significant issue in urban areas due to air pollution and increased industrial activity [6]. Dust and particulates released from fossil fuel combustion and construction activities lead to a reduction in solar irradiance. Consequently, this decline in irradiance negatively affects voltage and current values, resulting in a decrease in PV panel performance [7]. Moreover, atmospheric deposits such as dust, air pollution, sea salt, and organic residues, in combination with meteorological conditions like wind speed, temperature fluctuations, humidity, snowfall, and hailstorms, can further reduce system efficiency [8–11]. Studies in the literature investigating the effects of dust and surface contamination on PV panel performance have particularly focused on environmental factors such as wind, precipitation, temperature, humidity, and solar radiation. It has been found that the smaller the dust particle size, the greater the shading effect on PV panels. Higher solar radiation, wind speeds, and atmospheric humidity also lead to thicker dust accumulation on PV surfaces, thereby reducing efficiency. On the other hand, some surface cleaning occurs naturally following rainfall, and steeper panel tilt angles facilitate the removal of dust from surfaces [12].

In another study, the accumulation of dust on PV panels under the influence of wind barriers was analyzed using computational fluid dynamics (CFD) simulations. Variables such as dust particle size, wind barrier height, and porosity were considered. Shear stress transport models were used to simulate airflow behavior around PV systems with wind barriers. The results showed that as the wind barrier height increased, the rate of dust accumulation on PV panels decreased to 8.62%, 7.98%, 7.54%, 7.27%, and 6.47%, respectively. The study identified the optimal wind barrier height as 2.5 meters [13]. A recent study conducted in Iraq investigated the impact of dust particles on PV panel performance. The experimental study was carried out at the University of Technology in Baghdad from March 15 to May 15, 2024. When dust density reached 10 g/m², the power output of the PV panel decreased by 34%. Furthermore, a nonlinear relationship was observed between the fill factor (FF), dust density, and conversion efficiency. Under a constant irradiance of 750 W/m², the PV panel efficiency dropped from 19.8% to 6.3%. Based on the study's findings, dust accumulation was found to reduce PV efficiency by 7.8% to 19.2%. The research emphasized the importance of developing effective cleaning strategies, especially in regions like Iraq where high dust levels and extreme temperatures are common [14].

Unlike the aforementioned studies, the present research involved the installation of a solar energy conversion system consisting of two PV panels with equivalent output power on the campus of the Faculty of Engineering at Trakya University. A hydrophilic nanocoating was applied to the surface of one panel to prevent dust accumulation, while the other panel was left in its standard state. For the experimental procedure, industrial iron foundry dust was uniformly distributed over the surface of all cells on both PV panels. Over a continuous five-week period, the voltage and current values of both panels exposed to iron foundry dust were recorded, and energy output was calculated and analyzed accordingly.

MATERIALS AND METHODS

A solar energy conversion system was installed on the south-facing side of the Engineering Faculty campus at Trakya University, as shown in Figure 1. The experimental setup consists of two polycrystalline photovoltaic panels, each with an equivalent output power of 100 W, along with a data recording system to monitor and analyze energy production values. The technical specifications of the photovoltaic panels used in the solar conversion system are presented in Table 1. Before the start of the experiment, both PV panels in the test setup were washed with water and allowed to dry completely. The initial conditions of the PV panels and the experimental setup are illustrated in Figure 1.

Figure 1. Experimental Setup

The technical specifications of the hydrophilic nanocoating applied to the surface of PV Panel A are presented in Table 1.

Table 1. Technical specifications of the nano coating material

Feature	Value
Density	0.81 g/ml
Viscosity	1.2 cP
Boiling point	78 °C
Ignition point	≤16.6 °C
Active components	<5% wt
Volatile Organic Content (VOC)	>85% wt
Color	Whitish transparent/translucent
Solvent	Ethanol

After the PV panel surfaces dried, a hydrophilic nanocoating in liquid form was manually applied to the surface of PV Panel A using a sponge. The properties of this liquid coating material are presented in Table 2. No treatment was applied to the surface of PV Panel B, which

was left in its standard condition. Subsequently, industrial iron dust obtained from a manufacturing site in an industrial region was uniformly sprinkled over all the cells on the surfaces of both PV panels. During this process, the tilt angle of the PV panels was fixed at 10° to ensure that the iron foundry dust would remain on the panel surfaces for a longer period without falling off.

Table 2 Technical specifications of solar PV module

Feature	Value
Brand and Module Cell type	Tommatech Polycrystalline
Maximum Power (P _{max})	100Wp
Voltage at maxime Power (V _{mp})	19.73V
Current at Maximum Power (I _{mp})	5.58A
Open Circuit Voltage (V _{oc})	23.22V
ShortCircuit Current (I _{sc})	5.81A
Maximum System Voltage	1000V
Maximum Series Fuse Rating	6.%A

Figure 2 illustrates the application of iron foundry dust onto the photovoltaic cells of PV Panel A and PV Panel B.

Figure 2. Iron Foundry Dust Deposited on the Surfaces of PV Panels

Following the application of iron foundry dust shown in Figure 2, voltage and current values produced by the PV panels were recorded daily from 07:00 AM to 07:00 PM over a period of five weeks. The control panel of the data acquisition device used for recording the data is shown in Figure 3.

Figure 3. Datalogger Used for Data Acquisition in the Experimental Setup

At the conclusion of the experimental study, the recorded voltage and current data were retrieved from the memory card of the system, and the energy output of the PV panels was calculated. Subsequently, graphs illustrating the power output and energy production of the PV panels were plotted.

RESULTS AND DISCUSSION

During the five-week experimental study, a random day May 11, 2025 was selected to capture instantaneous images of the photovoltaic surfaces of PV Panel A and PV Panel B, which are presented in Figure 4.

Figure 4. Surface Images of the PV Panels

During the experiments, May 11, 2025 was selected as a random day to capture images of the PV panel surfaces. As shown in Figure 4, a higher concentration of iron foundry dust was observed on the surface of PV Panel B, which was not treated with hydrophilic nanocoating. Under these conditions, the power output of PV Panel B was found to be lower, as illustrated in Figure 5.

Figure 5. Comparison of PV Panels' Power Output on a Random Day

As observed in Figure 5, PV Panel A, which was coated with the hydrophilic nanocoating, generated higher power throughout the day. Notably, between 12:00 and 15:00 when solar irradiation was most intense PV Panel A produced a peak power output of 70 W. During the same period, the power output of the standard PV Panel B did not exceed 55 W.

Similarly, Figure 6 shows that, consistent with the randomly selected day, the power output of PV Panel A remained higher throughout the day. Analysis of the experimental results identified May 26, 2025 as the day with the highest power output for both PV panels.

As shown in Figure 6, on May 26, 2025, during the period of highest solar irradiation between 12:00 and 15:00, PV Panel A produced power close to 80 W. In contrast, the standard PV Panel B achieved a maximum power output of 65 W during the same time interval. These results indicate a significant decrease in power output for PV Panel B, which was not treated with the hydrophilic nanocoating.

Analysis of the experimental data revealed that the lowest power output from the PV panels occurred on May 16, 2025. As observed in Figure 7, even on the day with the lowest output, PV Panel A with the hydrophilic nanocoating maintained a higher power output compared to PV Panel B.

Figure 6. Comparison of PV Panels' Power Output on the Day of Maximum Power Generation

Figure 7. Comparison of PV Panels' Power Output on the Day of Minimum Power Generation

As observed in Figure 7, on May 16, 2025, solar irradiation was low during the day, with insufficient sunlight recorded particularly between 12:00 and 13:40. Around 13:00, PV Panel A produced an instantaneous power output close to 35 W. During periods of low irradiation, even PV Panel A, which was treated with hydrophilic nanocoating, was unable to deliver sufficient power output. As shown in Figure 8, throughout the entire experimental period from April 22, 2025, to May 27, 2025, PV Panel A consistently generated more energy compared to the standard PV Panel B.

Figure 8. Comparison of Daily Total Energy Output from the PV Panels

As shown in Figure 8, on May 10, 13, 16, and 17, solar irradiation levels were very low, resulting in insufficient energy generation from both PV panels. Based on these results, it was determined that the application of the hydrophilic nanocoating on PV Panel A improved energy efficiency.

CONCLUSION

In this study, the effect of dust accumulation, which significantly reduces the energy output of photovoltaic (PV) panels, was investigated with a focus on hydrophilic nanocoating and iron dust. Throughout all experimental days, the PV Panel A treated with hydrophilic nanocoating generated more energy than the untreated PV Panel B. Analysis of the results showed that, under the same conditions and exposure to iron dust, PV Panel A produced 32.3% more energy compared to the standard PV Panel B.

On the day of highest energy production, May 26, 2025, PV Panel A generated 475.4 Wh of energy, while PV Panel B produced 378.7 Wh. PV Panel A with hydrophilic nanocoating produced 96.7 Wh (25.5%) more energy than the standard PV Panel B on this day. On the day

of lowest production, May 16, 2025, energy outputs of 19.5 Wh and 14.6 Wh were recorded for PV Panel A and PV Panel B, respectively. PV Panel A generated 4.9 Wh (33.6%) more energy than PV Panel B on that day. Over the entire recording period, the total energy production of the hydrophilic nanocoated PV Panel A was 13,485.6 Wh, compared to 10,197.0 Wh for the standard PV Panel B. This corresponds to an increase of 3,288.6 Wh (32.3%) in total energy output for PV Panel A relative to PV Panel B throughout the recording period.

ABSTRACT

Solar energy is considered a sustainable resource due to its infinite availability, safety, and the fact that it does not emit greenhouse gases into the atmosphere. Numerous academic studies have been conducted on photovoltaic (PV) panels used in electricity generation from solar energy. While rooftop installations are the most common applications in buildings, interest in alternative installations such as balcony railings, terrace shading systems, and facade cladding is increasing due to various constraints and site-specific conditions. In high rise buildings in particular, limited roof space or an unfavorable roof orientation makes PV facade applications a viable alternative. However, for such applications, accurately modeling the solar energy conversion system and conducting thorough technical and economic analyses are of critical importance. Therefore, before installation, the system should be modeled to analyze investment cost, energy efficiency, and payback period. One of the most commonly used software tools for modeling and simulating solar energy systems is PV*Sol. In this study, a 75-kW self consumption solar energy system was designed and analyzed using PV*Sol software, based on the location data of the Agricultural Research Institute Building in Edirne, Turkey. Two scenarios were evaluated: installation on the South facing roof and, on the South, facing facade of the building. The results show that for both applications, the total investment cost is ₺2,235,600. The payback period is 7.9 years for the rooftop installation and extends to 8.5 years for the facade application. Additionally, it was determined that the rooftop system would prevent approximately 49.244 kg of CO₂ emissions annually.

Keywords: Energy, Solar Energy, PV*Sol Software, PV Panel, Sustainability

INTRODUCTION

In many countries around the world, the continued reliance on fossil based energy sources leads to environmental pollution, economic challenges, and climate change. Therefore, the transition to renewable energy and the diversification of energy sources have become increasingly important. Solar energy is widely preferred due to its inexhaustible nature, cleanliness, and the absence of harmful emissions. However, before installing a solar energy system, it is crucial to select appropriate system components based on the specific site conditions and to conduct thorough technical and economic analyses. Various simulation programs are used for this purpose, offering results that closely approximate real world values. One of the key parameters influencing these analyses is the proper positioning of photovoltaic

(PV) panels. As is well known, PV panels in solar power plants in Türkiye are typically installed facing south at an optimal tilt angle based on the location's geographical characteristics. However, in certain cases such as when the roof orientation is unsuitable, the available roof area is insufficient, or shading is present installing PV panels vertically on the South facing facade of a building becomes a viable alternative. Vertical PV panels on building facades are particularly suitable for high rise structures [1–2]. Moreover, the application of solar energy systems in the construction sector plays a significant role in urban transformation projects [3–4]. The depletion of fossil fuel reserves and the rising cost of energy have further increased interest in renewable energy sources in many parts of the world [5–6–7]. Integrating PV panels into the facades of tall buildings provides substantial surface area for energy generation [8]. However, conventional silicon based PV panels are often heavy, which poses challenges for vertical facade installations and reduces their adoption [8–9].

A review of the literature reveals several studies aimed at improving the energy efficiency of building integrated photovoltaic (BIPV) systems. In one approach, phase change materials and carbon foam were applied to the rear surface of facade mounted PV panels, resulting in an energy efficiency improvement of between 12.64% and 27.35% [10]. In two case studies conducted in Lisbon, Portugal, predictive models were developed to estimate the potential of rooftop and facade PV panels using light detection and ranging (LiDAR) data and local meteorological records. According to the analyses, PV installations on roofs and facades could meet approximately 50% to 75% of the total electricity demand [11]. In a modeling and simulation study where the parameters limiting the integration of photovoltaic (PV) panels were categorized into three groups facade functionality, suitability, and surrounding obstructions it was determined that approximately 31% of the total vertical facade area is suitable for PV system installations. Although there are certain constraints regarding material selection and geometric uncertainties in facade integrated PV systems, the study emphasized that such installations are necessary for urban renewal projects [12]. In another simulation study, the potential for installing solar energy systems on the rooftops and facades of buildings in densely populated areas of Singapore was analyzed. The structural characteristics of the buildings, the distance between buildings, and plot dimensions were examined for their impact on rooftop and facade installations. Simulations were conducted for 12 existing districts in Singapore. The results suggested that standardizing roof shapes, facade orientations, and building heights could increase the feasibility of PV installations and reduce shading effects [13].

In Nigeria, a study focused on reducing energy consumption through PV panel installations on the facades of institutional buildings. The research investigated facade design, the selection of suitable solar panels, and the choice of facade wall materials. It was concluded that thin film and monocrystalline PV panels are suitable for facade applications. Moreover, the integration of PV systems into facades was found to offer not only renewable energy generation but also thermal benefits that contribute to the building's heating requirements [14]. Another study analyzed key parameters such as heat transfer across the facade, cooling demand, and daylight utilization. It was found that more than 30% of the building area had a daylight factor ranging between 1.0% and 3.5%. From an economic perspective, it was observed that the payback period of double laminated monocrystalline PV glass is relatively long [15]. In a recent study, the design and retrofitting of solar energy systems in existing buildings were examined by quantitatively investigating the relationships between PV capacity, tilt angles, and resulting building energy consumption. Using a numerical simulation tool, the fluctuations in indoor temperatures throughout the year, changes in energy consumption, and PV power generation potential were thoroughly evaluated both before and after retrofitting. The findings showed that all improvement scenarios led to reductions in indoor temperatures and energy consumption

during the summer months. Additionally, this configuration was projected to reduce carbon dioxide (CO₂) emissions by 128.90 tons per year through energy savings in existing buildings [16].

In contrast to previous studies in the literature, this study presents a technical and economic analysis of vertically mounted photovoltaic panels (at a 90° angle) on the south-facing external wall of a building, specifically in cases where there is insufficient space on the south facing roof for solar energy system installation.

MATERIALS AND METHODS

This study aims to evaluate the energy production and economic performance of photovoltaic (PV) panels to be integrated into the roof and south-facing façade of the Agricultural Research Institute building located in Edirne, Türkiye. The solar energy system, with a planned output capacity of 75 kW, was designed using the PV*Sol simulation software. The system was configured using 108 CWT690 monocrystalline PV modules, each with a capacity of 690 W, along with one SUN2000-60KTL-M0 inverter and other system components. For the simulations, the tilt angle was set to 32° for the rooftop installation and 90° for the south facing vertical facade, based on the site's geographic location. A visual representation of the installation site is shown in Figure 1. The study focuses on a grid connected self-consumption PV system, in which panels are mounted both on the roof and vertically on the façade. Energy efficiency under both scenarios was examined in detail. Based on the results of the simulation analyses, the total annual electricity generation from the rooftop mounted and vertically façade-integrated PV panels was calculated and illustrated graphically.

Figure 1. Location view of the Agricultural Research Institute Building [17].

For the simulation analysis, the building location shown in Figure 1 was first selected, followed by the configuration of other system components. Additional system specifications are presented in Table 1.

Table 1. PV Generator Module Area [17].

	Module Area
PV Modules	108 x CWT690-132TNB12-V (v2)
Manufacturer	CW Energy Engineering Trade and Industry Limited Company
Tilt Angle (°)	32 / 90
Azimuth Angle (°)	Southwest 225
Mounting Type	Roof-integrated rear ventilation / Wall-integrated rear ventilation
PV Generator Area (m ²)	335,5
Shading (%)	0

As shown in Table 1, a surface area of 335.5 m² was utilized for the arrangement of photovoltaic panels.

RESULTS AND DISCUSSION

Based on the components of the solar energy conversion system designed for the Agricultural Research Building, the electricity production estimates obtained from the PV Sol simulation software are presented in Table 2.

In the case of implementing a grid-connected, self-consumption solar energy conversion system on the building's roof, an annual electricity production of 1406 kWh would be achieved, as shown in Table 2.

Table 2. Production Estimate [17].

	Production Estimate (South, Roof)	Production Estimate (South, Wall)
PV generator output (kWp)	74,52	74,52
Annual Specific Energy Yield (kWh/kWp)	1406.00	926.10
System Performance Ratio (PR) (%)	89,06	88,83
Electricity Exported to the Grid (kWh/year)	104,786	69,024
Grid Feed-in During the First Year (Including Module Performance Degradation) (kWh/Year)	104,786	69,024
Consumption in Standby Mode (Inverters) (kWh/Year)	11	11
Prevented CO ₂ Emissions (kg/year)	49,244	32,436

As shown in Table 2, when photovoltaic panels are integrated into the south-facing wall surface of the building instead of being installed on the roof, the annual electricity production decreases to 926 kWh. Along with the reduction in electricity generation due to the integration of photovoltaic panels into the building wall, the amount of prevented carbon dioxide (CO₂) emissions also decreases.

The financial analysis results of two different design implementations, installed with the same investment cost, are presented in Table 3. When the solar energy conversion system is applied to the roof, the payback period is 7.9 years, whereas integrating the system into the building's south-facing wall increases the payback period to 8.5 years.

Table 3. Financial Analysis [17].

	Gain from Roof Application	Gain from Wall Application
Total Investment Cost (₺)	2,235,600.00	2,235,600.00
Internal Rate of Return (IRR) (%)	59,46	55,53
Payback Period (Years)	7,9	8,5
Electricity Production Cost (₺/kWh)	1.1824	1,7951
Energy Balance / Grid Feed-in Concept	Full Grid Feed-in	Full Grid Feed-in

As shown in Table 3, the unit cost of electricity generated is lower for the roof installation, depending on the system design. However, despite these advantages, certain practical challenges encountered in roof applications such as insufficient space and the absence of a south-facing roof indicate that photovoltaic panels may be integrated into the building's south-facing wall instead.

Based on the simulation results, the total energy yield from the solar energy system is estimated to be 104,786 Wh for the roof installation (with a south orientation of 32°) and 69,024 Wh for the integration on the south-facing wall (90° orientation).

CONCLUSION

In this study, a 75 kW self-consumption solar energy conversion system for the Agricultural Research Institute Building in Edirne Province was designed using PV Sol simulation software, considering both the south-facing roof installation and integration on the south-facing wall surface, followed by technical and economic analyses. For both designs, the investment cost was 2,235,600 TRY. The payback period for the roof installation was found to be 7.9 years, whereas the integration of photovoltaic panels on the building's south facing wall extended this period to 8.5 years. Moreover, the unit cost of energy production was determined to be lower for the roof application. Additionally, it was observed that implementing the solar energy system on the roof would prevent approximately 49,244 kg of CO₂ emissions annually. Despite these advantages, when challenges such as unsuitable south orientation of the roof for mounting, insufficient roof area, and shading are encountered, integrating photovoltaic panels perpendicularly on the building's south facing wall emerges as a viable alternative solution.

IMPACT OF REGULAR WATER-BASED CLEANING ON THE ENERGY EFFICIENCY OF PHOTOVOLTAIC PANELS

Dinçer Akal

Trakya University, Engineering Faculty Mechanical Engineering Department, Edirne, Turkey

e-mail: dincerakal@trakya.edu.tr

ABSTRACT

Solar energy is abundant in many countries worldwide and is easier to use compared to other renewable energy sources. However, the overall conversion efficiency of photovoltaic (PV) panels used for electricity generation from solar energy remains relatively low. Maximizing the efficiency of solar energy systems requires maintaining the cleanliness of PV panel surfaces. In this study, the effect of periodic cleaning of PV panel surfaces with only water on energy efficiency was investigated. An experimental solar energy conversion system was installed on the campus of Trakya University Faculty of Engineering. The setup included two polycrystalline PV panels (PV A and PV B), each with a nominal output power of 260 W. Initially, both PV panels were cleaned. Subsequently, PV A was left uncleaned, while PV B was washed with only water at 30 day intervals. Daily energy production data from both panels were recorded over a five month period. At the end of this period, the energy output of PV B, which was cleaned monthly with water, was approximately 3% higher than that of the uncleaned PV A. The experimental results indicate that washing PV panels with water every 30 days can improve energy efficiency. Future studies are expected to build upon these findings by comparing more frequent cleaning intervals to evaluate their effects on energy performance in greater detail.

Keywords: Energy, PV panel, Water cleaning, Efficiency

INTRODUCTION

In recent years, electricity generation from solar energy has become increasingly preferable among renewable energy sources. Compared to other alternative energy systems, solar energy systems are expected to become even more widespread in the future due to their advantages such as ease of installation, the absence of moving parts, economic feasibility, and long operational lifespan. While environmental concerns related to the use of fossil based energy sources persist globally, solar energy is considered a promising solution for electricity generation [1–3]. It is estimated that by the year 2050, photovoltaic (PV) panels will contribute approximately 25% of the world's total electricity production [4]. Despite these developments, the conversion efficiency of photovoltaic panels remains relatively low under current conditions. Furthermore, depending on operational factors, this efficiency may decline even further. The accumulation of dust and dirt on PV panel surfaces significantly affects the system's energy efficiency. Dust particles on the panel surface not only block light from reaching the solar cells but also lead to an increase in cell temperature. As a result of these adverse conditions, energy losses increase, reducing the output power of the PV panel. Global case studies have shown that coal dust (up to 64%), fine sand (32%), and gypsum dust (30%) can reduce energy output significantly [1]. On the other hand, although the efficiency of PV panels varies depending on production technology, factors such as solar irradiance, ambient temperature, wind speed, and tilt angle also contribute to performance losses [5–6]. After the

effects of solar irradiance and temperature, dust accumulation is the most significant factor causing a decrease in PV output power [7], as dust formation restricts the transmission of solar radiation to the module cells [8–9].

A review of the literature on improving energy efficiency through PV panel cleaning reveals that manual cleaning may damage photovoltaic surfaces due to the pressure exerted by chemical cleaning solutions used to remove accumulated dust and particulates [10]. Furthermore, the use of sprinkler systems for PV panel cleaning can lead to excessive water consumption, which poses a challenge in regions with limited water resources and from a sustainability perspective [11]. Waterless cleaning methods, such as self-cleaning superhydrophobic and superhydrophilic coatings, rely on gaseous substances reacting with hot surfaces, but controlling energy efficiency under these conditions is difficult. Therefore, further research is needed regarding factors such as transparency, anti reflective properties, and durability [12]. In one study conducted under the climatic conditions of Oman, a six month performance evaluation of a PV system was carried out to assess the impact of dust accumulation and determine optimal cleaning intervals. Using a manual cleaning method, the study found that efficiency dropped by 28% in the uncleaned PV array [13].

Unlike previous studies, this research experimentally investigates the effect of water only cleaning on energy efficiency in a PV system installed at Trakya University Faculty of Engineering Campus, located in Edirne, a region with relatively low dust levels. The PV panel surfaces were cleaned at 30 day intervals using only water.

MATERIALS AND METHODS

To investigate the effect of surface contamination and dust accumulation on photovoltaic (PV) panels, a solar energy system was installed at the Trakya University Faculty of Engineering Campus, as shown in Figure 1. In the experimental setup, two identical PV panels with a rated power of 260 W were used. The technical specifications of the PV panels employed in the study are presented in Table 1. At the beginning of the experiment, both PV Panel A and PV Panel B were cleaned using only water and a sponge. Subsequently, the energy production data from both panels were recorded over a five month period. Following the initial cleaning, PV Panel A was left unwashed and unmaintained throughout the entire test period. In contrast, PV Panel B was cleaned every 30 days using only water and a sponge. In other words, while PV Panel A remained completely uncleaned, PV Panel B was washed a total of five times. This setup enabled an evaluation of the impact of water based cleaning on the energy efficiency of PV panels. At the end of the five month experimental period, the total energy output of both panels was analyzed and visualized through comparative graphs.

The voltage and current values obtained from the PV panels were recorded throughout the experimental period using a system specific data logger, as shown in Figure 2. Based on these voltage and current values, the output power and the total amount of energy produced by the PV panels were calculated.

Figure 1. Photovoltaic Panel Installation

Figure 2. Data logger system used for recording PV panel voltage and current values

All technical specifications of the PV panels used in the solar energy conversion system are presented in Table 1.

Table 1 Technical specifications of solar PV module

Feature	Value
Maximum Power (Pmax)	260 W
Power Tolerance	0~+3%
Maximum Power Voltage (Vmp)	31.1 V
Maximum Power Current (Imp)	8.37 A
Open Circuit Voltage (Voc)	38.1 V
Short Circuit Current (Isc)	8.98 A
Nominal Operating Cell Temperature (NOCT)	45±2°C
Maximum System Voltage	1000 VDC
Maximum Series Fuse Rating	15 A
Operating Temperature	-40°C~+8°C
Application Class	A
Weight	18.5 kg
Dimension	1650×992×40 (mm)

RESULTS AND DISCUSSION

Following the experimental study, the energy production values obtained from PV Panel A (which was not cleaned) and PV Panel B (which was cleaned once every 30 days using only water) were analyzed. After the initial conditions, PV Panel B, which was cleaned with water once every 30 day interval, consistently produced more energy each month compared to the uncleaned PV Panel A. At the end of the five month period, the total energy outputs of both PV panels were compared. The cumulative energy production values for PV Panel A and PV Panel B are presented in Figure 3.

Figure 3. Monthly Total Energy Production of the PV Panels

As shown in Figure 3, PV Panel B, which was cleaned only once every 30 days, produced more energy each month. When the total energy production was examined on a monthly basis, a larger difference in energy output between PV Panel B and PV Panel A was observed during the 6th, 7th, and 8th months. This suggests that dust and dirt accumulation on the PV panel surfaces have a greater negative impact on the output power of the panels during months with higher solar irradiance levels. Based on the results of this study, it was concluded that regular cleaning and washing of PV panels leads to an increase in energy efficiency. At the end of the experimental study, surface images of both PV panels under the current conditions

were captured and are presented in Figure 4. Throughout the study, the surface of PV Panel B, which was cleaned once every 30 days using only water, appeared significantly cleaner compared to the surface of PV Panel A, which was never cleaned, as illustrated in Figure 4.

Figure 4. Surface Contamination Images of PV Panels After the Experiment

As shown in Figure 4, dust and dirt accumulation on the surface of PV Panel A has been found to reduce its energy efficiency. Therefore, regular cleaning or washing of PV panels is essential to prevent the formation of contamination and dust. In Figure 5, the output power profiles of PV Panel A and PV Panel B are compared for a randomly selected day in July, the month with the highest solar irradiance during the five month experimental period. As observed in Figure 5, the output power of PV Panel B, which was cleaned with water, consistently remained higher than that of PV Panel A throughout the day. Although instantaneous output power of PV panels may fluctuate during the day, the critical parameter is the total amount of energy generated from a PV panel over the course of the day.

Figure 5. Comparison of the Output Power of PV Panels on a Randomly Selected Day in July

For the randomly selected day, it is observed that the output power of PV Panel B, which was cleaned with water, increases significantly during periods of high solar irradiance, particularly around midday.

CONCLUSION

In this study, the effect of dust and dirt accumulation on the surface of photovoltaic (PV) panels used in solar energy systems on energy efficiency was investigated. PV Panel B, which was manually cleaned with water at 30 day intervals on the installed solar energy system, produced approximately 3% more energy over a five month period. Data analysis from the system revealed that during the five month timeframe, the water cleaned PV panel generated 3122 Wh more energy compared to the uncleaned panel. Considering the large number of photovoltaic panels used in solar power plants, it is evident that regular cleaning with water alone can result in significantly higher energy yields throughout the year. In conclusion, regular cleaning of PV panel surfaces not only increases energy efficiency but also extends the operational lifespan of photovoltaic cells. Future studies using different cleaning agents may provide clearer insights into potential increases in energy efficiency.

ABSTRACT

During these last years, the important evolution in the computer field and the progress made in the methods of calculation of quantum chemistry make it possible to give a good prediction and a good description of the electronic properties of a given entity. In this work, we have used theoretical study of the substitution reaction by grafting of salicylic acetyl on a unit of epichlorohydrin. We have determined the purely theoretical parameters of the dipole moment (DM), the energy of the frontier orbitals, HOMO, LUMO and the energy gap by two methods HF and DFT, we have also calculated the characters DEN (Normal Electronic Demand) or DEI (request Electronic Inverse) on the substitution reaction of salicylic acetyl (aspirin) + poly (epichlorohydrin); we have calculated the HOMO/LUMO gap energies for the two combinations. The electronic chemical potential μ , and the nucleophilicity index (N). Local reactivity descriptors of aspirin and epichlorohydrin were calculated using the population analyzes of Mulliken and Hirshfeld by the method DFT/6-31 G(d,p) and also using the analysis of ESP population. A theoretical spectral study of the final product: IR, ¹³C NMR was carried out.

Keywords: Epichlorohydrin, HOMO, DFT, salicylic acetyl, nucleophilicity, Computational Chemistry.

INTRODUCTION

Computer-aided chemistry (Computational Chemistry), its applications can be used for elucidation and analysis of chemical structures, the processing of chemical information or even theoretical chemistry Justyna Krupa and al.2023. Very precise calculation algorithms are used to minimize the total energy according to the structural parameters and to predict the most stable structure of the studied compounds Mikołaj Sadowski and Karolina Kula, and al.2024. Computational chemistry methods such as molecular simulations, density-functional theory (DFT), and ab initio approaches are crucial for analyzing the behavior of molecules during the

reaction and the transformation of forms before and after the reaction, which is essential for addressing challenges related to multifunctional polymer utilization and environmental impact. In this work, the main objective is to use a theoretical study using Gaussian09, of the substitution reaction by grafting of AcSa on units of epichlorohydrin polymer, to be able to confirm the obtaining of the new multifunctional polymer schematic 1. The energy separation of the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) has been used as a simple indicator of kinetic stability Ping Bao, Xiaowei Wang and al.2024. Peng Xi, Fengling Sun.2024 noted that the HOMO-LUMO gap reflects the chemical stability of the molecule. In general, an atom with a higher density HOMO should have a higher ability to remove an electron, while an atom with a higher density occupied by a LUMO should have a higher force to gain an electron R. G. Parr and W. Yang 1989. On the other hand Mulliken atomic charges play an important role in understanding the chemical reactivity of compounds R. S. Mulliken. 1932, 1939.

The aim of the present work is to predict the nucleophilic and electrophilic attack sites of some classes of chemical reactions using reactivity indices derived from the density functional theory (DFT). First, we have calculated the global and local nucleophilicity indices. Then, we have conducted a theoretical study of a substitution reaction: epichlorohydrin and acetylsalicylic acid. The local and global reactivity indices derived from the DFT are very reliable for the prediction of electrophilic or nucleophilic attack sites provided that efficient methods (B3LYP) are used for the energy and geometric calculations of the reactants.

Schematic 1 : Chemical modification of PECH by AcSa

MATERIAL AND METHOD

Optimized Geometries and Frontier Molecular Orbitals

Gaussian software was used in order to carry out all the structure optimizations studied with the following DFT. The calculation was launched with the correlation exchange functional B3LYP and the Gaussian basis 6-31G (p,d). The latter has the same denomination, where the set of functions p added to the hydrogens and the set of functions d added to the other heavy atoms is well defined.

First, the theoretical calculation was made with the DFT method using the functional B3LYP (Becke Lee-Yang- Parr) and the base 6-31Gdp, for the latter. Optimization with this method gave us almost similar conformations, the latter having the lowest possible formation energy, hence the most stable conformation.

RESULTS AND DISCUSSION

OPTIMIZATION OF OBTAINED PRODUCT

Calculation details The DFT/B3LYP and 6-311++G(d,p) methods were used to optimize the molecular structures of polymer obtained. The programs Gaussian09W and GaussView5.0 were utilized to carry out all the necessary DFT calculations and visualizations. we obtained $E = -1070.545578$ au

Figure 1 : B3LYP/6-31G(d) computed structure of the graft polymer

HOMO-LUMO

Green and brown colors represent positive and negative phases, respectively. Data from the HOMOLUMO analysis are presented in Figure 2 .

	HOMO	LUMO
<i>acetyl salicylic</i>		
<i>epichlorohydrin</i>		

Figure 2: B3LYP/6-31G(d) HOMO–LUMO of *acetyl salicylic* and *epichlorohydrin*

To clarify the characters DEN (Normal Electronic Demand) or DEI (Inverse Electronic Demand) on the substitution reaction of salicylic acetyl and PECH; the HOMO-LUMO gap energies for the two combinations were calculated (chemical potential μ , and the nucleophilicity index (N)) (Table.1).

Table.1: B3LYP/6-31G(d) HOMO and LUMO energies as well as global reactivity indices for salicylic acetyl and epichlorohydrin, given in electronvolts [eV]

	LUMO	HOMO	$\Delta E(I)$ NED	$\Delta E(II)$ IED	μ	H	S	Ω	NOT
Salicylic acetyl	-0.069	-0.258	-0.288	-0.198	-0.164	0.189	2,640	1.935	2.326
Epichlorohydrin	0.029	-0.267	0.288	0.198	-0.119	0.297	1.685	0.652	2.089

$$\Delta E(I) = \text{HOMO}(\text{salicylic acetyl}) - \text{LUMO}(\text{epichlorohydrin}),$$

$$\Delta E(II) = \text{HOMO}(\text{epichlorohydrin}) - \text{LUMO}(\text{salicylic acetyl})$$

Table .1 show that the energy difference corresponding to the HOMO (salicylic acetyl) / LUMO (epichlorohydrin) combination is lower than that corresponding to the HOMO (epichlorohydrin) / LUMO (salicylic acetyl) combination, which shows that the Salicylic acetyl behaves as an electron donor (nucleophile) and epichlorohydrin as an electron acceptor (electrophile).

THEORITICAL SPECTRUM STUDY

Theoretical study of the Infra-Red Spectrum of the graft polymer

Examination of the theoretical IR spectrum (Figure 8) of the modified polymer has enabled us to identify the main intensive characteristic bands with the frequencies 1168 cm^{-1} , which indicates the absorption of the COC group of the ether, a band absorption located at 1456 cm^{-1} which corresponds to the aromatic HC group, an absorption band located at 653.184 cm^{-1} from the CH of the deformation, is a value of 1667.55 cm^{-1} which characterizes the elongations of the aromatic C=C bond. Table.2 brings together the main characteristic bands of the graft polymer.

Table.2: The main characteristic IR bands of the graft polymer.

Connection	IR EXP (cm^{-1})	FRQ(cm^{-1})/ DFT	FRQ(cm^{-1})/HF	Intensity
C _{tet} -H valence	2900-2877	2966	3117	2 middle bands
aromatic C=C	1485-1636	1476	1612-1777	3 OR 4 strong bands
Aromatic CH	709-762	716-796	1097	2 strong bands
CH deformation	1387-1485	1338-1405	1336-1386	2 strong bands
CO valence	1295	1076-1141	1149	thin band
C=O Ester	1636-1688	1735	2038	thin band

Figure 1: Theoretical IR infrared spectrum of the graft polymer by the methods HF-DFT

¹³C NMR spectrum of the graft polymer

¹³C NMR spectrum (Figure 4) allowed us to have the main chemical shifts of the different groups which characterize the graft polymer, we observe:

-A signal of 122 ppm which characterizes the displacement of carbon 17, 34 ppm signal, indicates the chemical shift of carbon 21 , and the aromatic carbon of C23 –C28 comes out between 40 and 72 ppm.

Figure 2 ¹³C NMR spectrum calculated by DFT of the graft polymer

LOCAL DESCRIPTORS OF AcSa REACTIVITY CALCULATED USING MILLIKEN AND HIRSHFELD POLUPLATIONS ANALYSIS

11C	0.006191	0.14567	0.33796082				

The local reactivity index f_k^- , for the Mulliken and Hirshfeld population analysis provided the greatest value at the O 12 site. The latter should be the most reactive site with respect to an electrophilic attack, therefore the more nucleophilic.

CONCLUSION

The DFT calculations at the B3LYP/6-31G dp level is used effectively to describe the reaction of the substitution of the chlorine group in the reaction of the grafting of acetylsalicylic acid on epichlorohydrin chain.

Analysis of HOMO/LUMO gaps, chemical potential μ and the global electrophilicity index ω indicates the NED character, and the IED character for the substitution reaction are calculated. Finally, it can be said that calculations of activation energies and reactivity indices derived from the conceptual DFT of both addition and substitution reactions successfully predict the experimental regioselectivity.

ABSTRACT

The present study aims to evaluate the impact of transitioning from conventional soil tillage to minimum tillage technology in a maize crop, cultivated over a three-year period (2022–2024) in the village of Lanurile, Constanța County, Romania. The experiment was conducted under real farm conditions and involved three late-maturing maize hybrids: DKC 5810, P0900, and P0216. The crop was grown on partially irrigated land. Soil preparation consisted of a single pass with a cultivator, followed by precision sowing, while all other technological inputs (fertilization, crop protection, and irrigation management) were kept constant across the hybrids and over the years.

The agromorphological and biometric determinations revealed superior performance for the DKC 5810 hybrid, followed by P0900. Differences in productivity parameters, such as grain weight per ear and thousand-kernel weight (TKW), were statistically validated using one-way ANOVA tests, confirming significant distinctions between hybrids ($p < 0.05$). The DKC 5810 hybrid recorded the highest average kernel weight and TKW, while also achieving the greatest yield per hectare. P0900 also demonstrated high adaptability and yield potential, particularly under irrigation. In contrast, P0216, although showing vigorous vegetative development, accumulated lower grain mass and yielded less compared to the other two.

Climatic analysis over the study period showed a consistent increase in mean annual temperatures and a significant decrease in rainfall, especially during critical phenological stages such as flowering and grain filling. These climatic trends emphasized the importance of water management. The irrigation applied in four key growth stages successfully offset part of the rainfall deficit and supported optimal crop development.

The results demonstrate that minimum tillage, when properly implemented under the specific pedoclimatic conditions of Dobrogea and combined with efficient irrigation and hybrid selection, can ensure competitive yields. This conservation practice reduces soil disturbance, minimizes erosion and compaction, and preserves soil moisture critical factors in semi-arid regions. Therefore, minimum tillage represents a viable and sustainable alternative to conventional tillage in areas facing water scarcity and climate variability.

These findings highlight the importance of hybrid selection aligned with specific tillage practices and climate adaptability. DKC 5810 is recommended for high-input, irrigated systems, while P0900 proves stable and productive in moderately intensive conditions. Further research is encouraged across other regions to validate these results and guide sustainable maize production strategies in Romania.

Keywords: minimum tillage, maize hybrids, sustainable agriculture, irrigation, climate change

INTRODUCTION

Cereals represent the crop group with the widest distribution and the greatest importance for human nutrition, providing approximately 60% of total proteins, 15% of lipids, and around 70% of carbohydrates, contributing 50–60% to the global caloric intake (Roman et al., 2015; Dobre, 2019). The success of cereal crops is explained by a combination of favorable factors: high ecological plasticity, complete mechanization, easy storage, and multiple utilization possibilities – human food, animal feed, industry, biofuels (Messegue, 2000).

Maize (*Zea mays* L.) holds a central place among cereals, both in terms of cultivated area and versatility of uses. In Romania, maize is extensively cultivated due to its nutritional value and high production capacity, being used for human consumption, animal feed, and industrial purposes (Cristea et al., 2004; Ion, 2010). In human nutrition, maize appears in various forms: flour (polenta), flakes, sweet corn, or popcorn (Paukert, 2021). Industrially, maize kernels are a raw material for obtaining starch, glucose, oil, as well as products such as bioethanol, spirits, and starch-based cosmetics (Petcu and Martura, 2018). However, the largest part of global production (over 60%) is destined for animal feed, being considered an essential forage, especially for ruminants (Sin, 2000).

Globally, maize is cultivated up to 59° northern latitude and 43° southern latitude, demonstrating great adaptability. Romania benefits from favorable soil and climatic conditions, being one of the European countries with significant maize cultivation areas (Popescu, 1995; Panaitescu and Niță, 2011). Nevertheless, achieving maximum productive potential requires the application of modern technologies that address current climatic challenges and agricultural sustainability requirements (Petcu and Martura, 2018).

In this context, in recent years there has been a growing interest in adopting conservation tillage technologies, such as minimum tillage, which limit mechanical interventions on the soil, thus reducing compaction, water loss, and erosion. Recent studies (FAO, 2023; ISTIS, 2024) confirm the effectiveness of these practices in maintaining soil structure and increasing farm sustainability. In Romania, although conventional technology remains predominant in many regions, more and more farms are exploring conservation methods, especially in drought-affected areas or where input costs must be reduced.

This study analyzes the technological transition from conventional soil tillage to minimum tillage in a maize crop on a farm located in Lanurile, Constanța County, over a three-year period, using three hybrids and maintaining the other technological elements constant. The purpose of the study is to evaluate the impact of this transition on yield, crop economics, and the adaptability of the hybrids to the new soil working conditions.

In the context of climate change and increasing pressures on natural resources, adopting conservation technologies such as minimum tillage represents a strategic direction for sustainable agriculture, with reduced impact on soil structure and soil biodiversity. Recent studies highlight that these technologies can contribute to reducing fuel consumption, conserving soil moisture, and maintaining fertility in semi-arid areas such as Dobrogea (Popa et al., 2023). Furthermore, the selection of maize hybrids with high potential and enhanced adaptability to variable pedoclimatic conditions is essential in the current context. Recent results emphasize the need for field testing of biological material in correlation with cultivation technology in order to efficiently capitalize on productive potential (Ioniță et al., 2022).

This study makes a significant contribution by evaluating the long-term effects, under real farm conditions, of the transition from conventional to minimum tillage in maize cultivation using three commercial hybrids. The results provide concrete data on the impact of this technology on yield, crop stability, and economic efficiency, key aspects for adapting agriculture to climate challenges and promoting sustainable practices in semi-arid areas such as Dobrogea. Thus, the research complements the existing literature through an integrated

approach to soil tillage technology and hybrid selection, contributing to the optimization of agricultural management in the context of climate change.

MATERIAL AND METHOD

The aim of this study was the comparative evaluation of the performance of three late-maturing maize hybrids cultivated under minimum tillage system in a representative area of Constanța County, over a period of three consecutive years. The study focused on analyzing the agro-biological and economic performances of the three hybrids under the region's specific soil and climatic conditions, in the context of transitioning from conventional soil tillage technologies.

The experiment was carried out on the farm of I.I. Iancu Ionuț, located in Lanurile, Constanța County, in the center of the Medgidia Plateau. The locality is situated approximately 50 km from the city of Constanța. The total area of the commune is 421 hectares of intravilan (built-up area) and 18,071 hectares of extravilan (non-built-up area). According to climatic data, the area belongs to the temperate-continental steppe climate type, characterized by an average annual temperature of 11.12°C, with January minimums of 0.2°C and July maximums of 22.1°C. The average annual precipitation is around 428 mm. The dominant soils are fertile chernozems, typical of steppe regions, favorable for agriculture.

The main agrotechnical characteristics of the experimental area: the preceding crop was wheat, and maize crops were established on 60 ha, 57 ha, and 85 ha in the years 2022, 2023, and 2024, respectively. Sowing was carried out after a shallow tillage operation using a combinator, uniformly applied in all three springs (characterized by cool and wet conditions, with persistent rainfall in April 2022 and 2023), aimed at accelerating soil warming and fragmenting remaining plant residues. This was the only soil intervention prior to sowing, specific to the minimum tillage system.

All care operations and phytosanitary treatments were identical across the three growing seasons, to allow for an objective evaluation of the hybrids' response exclusively to soil technology and annual pedoclimatic conditions.

Regarding biological material, three late-maturing maize hybrids registered in the Official Catalogue of Plant Varieties of Romania for 2022 and 2023 were used: DKC 5810 (Bayer): FAO 450–490 hybrid, RM 108, medium plant height, high seedling vigor, deep rooting system, without tillering; P0216 (Pioneer – Corteva): FAO 450 hybrid, high yield potential, suitable for early and optimal sowing, excellent performance under various growing conditions; P0900 (Pioneer – Corteva): FAO 450 hybrid, late-maturing, designed for intensive technologies (under irrigation or abundant rainfall), with good drought tolerance.

The experiment was conducted in open field conditions, under real farm conditions. Throughout the vegetation period, the main developmental phenophases of the hybrids were monitored (emergence, tillering, flowering, physiological maturity), tracking: vegetative growth dynamics, adaptability to climatic conditions, uniformity of emergence and development, behavior towards diseases and pests, and final yield per hectare.

Measurements were performed directly in the field, at the Iancu Ionuț Individual Enterprise farm, as well as in the laboratory, for detailed analyses regarding grain weight, thousand kernel weight (TKW), and other relevant qualitative characteristics.

RESULTS AND DISCUSSION

In the conducted experiment, the preceding crop was winter wheat, chosen in accordance with the predominant crop structure of the farm and the crop rotation system applied at the farm level. The distribution of crops and the average yields per hectare are presented in the tables below, providing an overview of the implemented crop rotation system.

Table 1. Crop structure within I.I. Iancu Enterprise during the years 2022–2024

Year	Crop plant				
	Wheat	Maize	Barley	Sunflower	Rapessed
2022	85	60	50	35	20
2023	83	57	40	40	30
2024	90	85	20	30	25

Table 2. Average crop yields within I.I. Iancu Enterprise during the years 2022–2024

Year	Crop plant				
	Wheat	Maize	Barley	Sunflower	Rapessed
2022	4830	6320	5070	2265	2145
2023	5000	6800	5150	2500	2500
2024	5500	7700	5050	2720	2300

Chemical fertilization within the study was carefully structured into three distinct stages, each corresponding to key developmental phases of the maize crop. The first stage, basic fertilization, took place in the autumn, prior to sowing. Here, 200 kg/ha of complex NPK fertilizer (20:20:20) was applied pre-emergence, aiming to provide the essential nutrients needed to support vigorous early growth. As the crop progressed, foliar fertilization was carried out at the 4-leaf stage, using Plonvit foliar fertilizer (produced by Intermag) at a rate of 2 L/ha, diluted in 300 liters of solution per hectare. This application was intended to stimulate physiological processes and enhance vegetative development. Later, at the 10-leaf stage, nitrogen fertilization was performed by administering 100 kg/ha of solid nitrogen, supporting the formation of inflorescences and the accumulation of dry matter within the grains.

Due to the nature of the minimum tillage system, where soil disturbance is minimized to conserve water resources and preserve soil structure, climatic conditions during the growing season played a pivotal role in influencing maize performance.

Soil preparation consisted of a single combinator pass, carried out two days before sowing: on April 24 in 2022, and April 25 in both 2023 and 2024. This light soil work enabled sufficient fragmentation, leveling, and aeration to create an optimal seedbed. Precision sowing was performed during the optimal window for the Dobrogea region: on April 25 in 2022, and on April 27 for the following two years. Favorable rainfall levels in April supported good seed germination and uniform seedling emergence across the experimental plots.

Climate analysis for Lanurile village over the agricultural period 2022–2024 (Table 3) revealed a consistent rise in monthly average temperatures compared to multiannual norms. The average annual temperature during the study period was recorded at 13.78°C, exceeding

the historical mean of 11.12°C by 2.66°C—an increase of approximately 24%. This upward trend persisted throughout the entire agricultural cycle, affecting not only the colder months, when soil water reserves are usually replenished, but also the critical vegetation stages, thereby intensifying plant metabolism and increasing their water demands.

Meanwhile, rainfall patterns showed a downward trend, with an annual average of 357.3 mm, marking a deficit of 70.8 mm relative to the multiannual average of 428.1 mm. This reduction, representing 16.55%, was especially evident during May, July, and August—months critical for maize development, as these periods coincide with the crop's highest water needs during pollination and grain formation. The resulting imbalance between water availability and plant demand likely posed a significant limiting factor for hybrid performance, particularly under conservation tillage systems where soil water reserves are crucial for crop success.

Table 3. Temperature and precipitation regime in Lanurile Locality during the agricultural years 2022–2024

Month	Average monthly temperature °C		Precipitation mm	
	Normală	2022-2024	Normală	2022-2024
XI	6.9	8,8	37,5	35,1
XII	2,1	3,6	32,2	28,5
I	0,2	4,8	31,6	40,6
II	1,1	2,9	32,8	22,1
III	3,9	6,8	22,1	24,5
IV	10,1	10,1	33,1	51,2
V	15,8	16,6	48,7	10,8
VI	19,9	21,8	52,6	44,6
VII	22,1	25,8	34,7	21,1
VIII	22,7	26,1	31,1	20,8
IX	17,2	21,2	40,8	30,1
X	11,5	16,9	30,9	27,9
Average	11,12	13,78	428,1	357,3

To objectively assess the statistical significance of the climatic differences between the normal multiannual values and those recorded during the study period, a descriptive statistical analysis was conducted, supplemented by a simplified one-way ANOVA test. The statistical results indicated p-values greater than 0.05 for both temperature ($p = 0.45$) and precipitation ($p = 0.16$), suggesting that, within this limited sample, the observed differences were not statistically significant. Nevertheless, the identified climatic trends—progressive warming and reduced precipitation—have clear agronomic relevance and can decisively influence crop performance, especially under minimum tillage systems.

Thus, it can be concluded that, although the statistical analysis did not confirm rigorous mathematical significance, the recorded climatic values (Figure 1) support field observations and may contribute to a better understanding of the yield variability of the analyzed hybrids under this technological system.

Figure 1. Comparative graphs of monthly average temperatures, monthly average precipitation, and multiannual normals

In the experiment, maize sowing was carried out at a depth of 6 cm using precision planters, maintaining a row spacing of 70 cm. The sowing density was set at 78,000 harvestable plants per hectare, adapted to the potential of the hybrids used and the availability of irrigation over 60 hectares out of the total 85 hectares cultivated with the three hybrids. The seeding rate was 27 kg/ha.

Weed control was performed both mechanically and chemically, following an integrated plant protection program. Three days after sowing, a pre-emergent herbicide treatment was applied using Callisto 480 SC (Syngenta) at a rate of 330 ml/ha to control broadleaf weeds and grasses. At the same time, the insecticide Decis Expert (Bayer) was applied at a rate of 125 ml/ha, targeting key pests during early vegetative stages, such as *Diabrotica virgifera virgifera* (Western corn rootworm) and *Helicoverpa armigera* (corn earworm). The solution was prepared at a volume of 250 L/ha.

Upon entry into the active vegetative growth phase, a post-emergent treatment with Equip (Bayer) herbicide was applied at a rate of 1.5 L/ha to combat invasive species such as *Setaria viridis* (green foxtail) and *Sorghum halepense* (Johnsongrass). This treatment was combined with the foliar fertilizer Plonvit (2 L/ha in 300 L solution/ha) and a preventive fungicide, as part of an integrated technological package.

Regarding disease control, two fungicide treatments were applied using Propulse (Bayer) at a rate of 1 L/ha. The first treatment was carried out at the 6–8 leaf stage, concurrently with foliar fertilization and the second herbicide application. The second treatment was applied during the stem elongation phase to prevent infections caused by *Helminthosporium turcicum*, the pathogen responsible for northern corn leaf blight.

Mechanical weed control was performed through inter-row cultivation at a depth of 8 cm, a stage that coincided with the application of solid nitrogen fertilization, completing the nutritional plan (Tables 4 and 5).

Table 4. Overview of treatments applied throughout the study period

No.	Stage	Product	Intervention Purpose
1.	Pre-emergence – 3 days after sowing	Calisto 480SC+Decis Expert	Weed and pest control
2.	Post-emergence 4–6 leaves	Equip+Plonvit+fungicide	Control of Johnsongrass, green foxtail, nutrition, and disease prevention
3.	Post-emergence 6–8 leaves	Propulse 1L/ha+Plonvit	Preventive fungicide treatment and foliar nutrition
4.	Stem elongation	Propulse 1L/ha	Control of northern corn leaf blight
5.	Mechanical cultivation	Inter-row cultivation at 8 cm depth	Mechanical weed control
6.	Nitrogen fertilization	100kg azot/ha	In-vegetation fertilization
7.	Irrigation 1	700m ³ /ha	Irrigation – stable emergence
8.	Irrigation 2	700m ³ /ha	Irrigation – 10–12 leaf stage
9.	Irrigation 3	700m ³ /ha	Irrigation – tasseling
10.	Irrigation 4	700m ³ /ha	Irrigation – maturation

Table 5. Technological schedule of maize during the study years

Due to the deficient rainfall regime during the agricultural years under study, four sprinkler irrigations were performed using a Hipodron-type linear pivot system. The first irrigation was conducted starting on May 20, applying 700 m³/ha, followed by a second irrigation in June when the plants were at the 10–12 leaf stage, with the same irrigation rate.

The third irrigation took place at tasseling, during the first ten days of July, and the fourth was performed in August, all maintaining a constant application rate of 700 m³/ha.

The controlled application of irrigation, correlated with minimum tillage practices, aimed to maintain a favorable soil moisture regime, especially during critical periods for maize development, thus supporting the physiological processes and productive potential of the analyzed hybrids.

The maize crop was harvested mechanically using a Claas Tucano 320 agricultural combine once the plants had reached full physiological maturity. This stage was determined by the stabilization of grain moisture around 17–18%, a threshold uniformly attained by all three hybrids analyzed. Harvesting operations began after October 19, with the latest harvest recorded on October 27, 2024. The entire process involved grain harvesting, after which the grains were transported to the farm headquarters for storage and conditioning. In preparation for marketing, grain moisture was reduced to below 15%, considered optimal for safe storage and trading. The production was sold during the autumn season of the respective agricultural years under study.

Within the study, several agromorphological field measurements were also carried out to highlight the development characteristics of each hybrid under the specific soil and climatic conditions and technological system applied. One such determination involved counting the number of plants and double ears over a 10-meter row length on two adjacent rows. Based on the averages recorded over the three years, it was observed that the hybrid DKC 5810 had 40 plants on the first row, 11 of which developed double ears, and 38 plants on the second row, with 9 showing this trait. For the hybrid P0216, 39 plants were recorded on the first row, with 9 double-eared, and 38 plants on the second row, 6 of which exhibited the same characteristic. Hybrid P0900 stood out with a higher plant density, having 40 plants on the first row and 41 on the second row, with 10 double-eared plants in each case. This feature suggests a strong generative branching capacity, indicating a superior production potential, especially under favorable nutrition and moisture conditions.

Further measurements involved counting the total number of ears present on the same 10-meter row sections to obtain a clearer picture of the fruiting capacity. Hybrid DKC 5810 recorded an average of 98 ears, P0216 had 92 ears, and P0900 achieved 101 ears. These data correlate with the observed presence of double ears and confirm the superior yield potential of P0900 compared to the other two hybrids.

Another parameter evaluated was the average plant height, considered an indicator of vegetative vigor and uniform development. DKC 5810 registered an average height of 2.39 m, ranging between 2.27 m and 2.51 m. P0216 showed an average of 2.31 m, with minimum and maximum values of 2.24 m and 2.42 m, respectively. P0900, although the most productive, had a slightly lower average height of 2.28 m, with a range between 2.17 m and 2.37 m. These relatively small variations indicate good uniformity of the experimental plots and specific adaptability of each hybrid to the minimum tillage system.

An additional field measurement was the determination of the ear insertion height. The results were as follows: DKC 5810 had an average ear height of 95.23 cm, ranging from 80.93 cm to 108.4 cm; P0216 recorded an average of 94.31 cm, between 82.10 cm and 103.3 cm; P0900 had an average of 93.33 cm, ranging from 80.6 cm to 105.6 cm.

The field measurements provide a detailed and rigorous overview of the phenotypic behavior of the three maize hybrids in the context of minimum tillage technology and a deficit rainfall regime supplemented by rationalized irrigation. Morphological characteristics and the total number of ears reveal differentiated but consistently high productive capacity, offering valuable insights for selecting the optimal hybrid under such technological systems.

To further evaluate hybrid performance under minimum tillage conditions, additional biometric determinations were performed at the farm's headquarters before harvest. These

included analyses of plant and ear weights at different preparation stages and detailed laboratory analyses of morphoproductive ear components.

For each hybrid, over the three study years, 10 mature plants with ears were harvested from two adjacent rows within the experimental plots. The first measurement focused on the total weight of plants at full physiological maturity. The average results were: DKC 5810: average plant weight of 770.27 g, ranging from 682.6 g to 830.2 g; P0900: average plant weight of 764.55 g, ranging between 667.1 g and 813.1 g; P0216: average plant weight of 731.59 g, with a range of 651.3 g to 811.1 g.

The second measurement targeted the weight of ears with husks, conducted two days before final harvest. After weighing the whole plants, the ears were separated and weighed individually. The average ear weights with husks were: DKC 5810: 289.3 g (ranging from 171.2 g to 358.8 g), with a residual plant biomass (excluding ears) averaging 480.92 g; P0900: 296.73 g (between 216.3 g and 331.1 g), with a residual biomass of 467.82 g; P0216: 230.64 g (ranging from 198.9 g to 308.2 g), with an average dry biomass of 500.95 g.

Detailed laboratory analyses continued with the measurement of ear weights without husks. After manually removing the husks, the ears were reweighed. The average values were: DKC 5810: 264.39 g (ranging from 150.8 g to 337.8 g), with an average husk mass of 24.91 g; P0900: 261.07 g (ranging from 194.7 g to 302.0 g), with an average husk mass of 35.66 g; P0216: 205.44 g (ranging from 168.9 g to 279.4 g), with an average husk mass of 25.2 g.

These results highlight clear differences in biomass structure and dry matter accumulation capacity among the three hybrids. Although hybrid P0216 exhibited a comparable total plant mass, the ear weights, both with and without husks, were visibly lower, suggesting a higher proportion of vegetative mass relative to productive structures. Conversely, hybrids DKC 5810 and P0900 demonstrated a more favorable ratio between total plant mass and ear mass, indicating superior efficiency in resource allocation toward generative structures.

Table 6. Measurement of husk-free ear weight at physiological maturity

Plant no.	Hybrid DKC 5810 (g.)	Hybrid P0900 (g.)	Hybrid P0216 (g.)
1.	223,4	215,2	184,1
2.	337,8	281,4	216
3.	318,8	296,9	279,4
4.	298,7	267,2	219,8
5.	279,2	280	224
6.	228,5	236,1	186,4
7.	150,8	269,2	188,6
8.	268,4	194,7	201,4
9.	258,3	302	168,9
10.	280	268	185,8
Minimum	150,8	194,7	168,9
Maximum	337,8	302	279,4
Average	264,39	261,07	205,44

To provide a detailed characterization of the morpho-productive elements of the analyzed hybrids, following the previous determinations, measurements of ear length without husks were conducted, followed by the determination of cob weight. This analysis was carried out on the same ears used for the weight measurements, after complete removal of the kernels. The average results, calculated over the three years of study, highlighted the following: the hybrid DKC 5810 presented an average ear length of 21 cm and an average cob weight of 22.39 g, with values ranging between 19.42 g and 27.5 g. For hybrid P0900, the average ear length was 20 cm, and the cob weight was higher, with an average of 25.59 g, ranging from 17.1 g to 35.8 g. Hybrid P0216 also recorded an average ear length of 20 cm, with an average cob weight of 23.03 g, ranging between 17.15 g and 31.61 g.

To evaluate the real productive potential of the ears, an additional determination was made by individually counting the kernels, one by one, on a batch of ten samples for each hybrid, across the three study years. The analysis revealed that: DKC 5810 had an average of 546 kernels per ear, ranging from 412 to 612. P0900 recorded an average of 554 kernels per ear, with values between 502 and 618. P0216 showed a lower average of 490 kernels per ear, ranging between 408 and 596.

These differences indicate a higher kernel density and spikelet fertility in hybrid P0900, supporting its previously observed productive performances.

The final determinations targeted the total kernel weight per ear, thousand kernel weight (TKW), and final yield per hectare (Table 7), obtained by weighing ten distinct samples for each hybrid. The average results over the three years of study were as follows: for DKC 5810, the average kernel weight per ear was 241.37 g, with values ranging between 128.7 g and 316 g. The thousand kernel weight (TKW) recorded an average of 442.07 g, and the average yield per hectare was 11,430 kg. P0900 showed an average kernel weight of 235.64 g (ranging from 171.5 g to 280.1 g), a TKW of 425.35 g, and an average yield of 10,780 kg/ha. In the case of P0216, the average kernel weight was 180.33 g, with values between 148.1 g and 233.6 g, a TKW of 408.02 g, and an average yield of 10,300 kg/ha.

Table 7. Measurement of grain weight per ear in the three maize hybrids under study

Plant no.	Hybrid DKC 5810 (g.)	Hybrid P0900 (g.)	Hybrid P0216 (g.)
1.	203,98	198,1	163,1
2.	316	258,3	189,3
3.	298,05	270,83	233,6
4.	274,6	232,28	198,78
5.	251,43	258,6	199,56
6.	206,4	211,25	162,3
7.	128,7	243,3	161,92
8.	248,08	171,5	184,25
9.	230,8	280,1	148,1
10.	255,7	232,2	162,4
Minimum	128,7	171,5	148,1
Maximum	316	280,1	233,6
Average	241,37	235,64	180,33

The obtained data highlight that the hybrid DKC 5810 exhibited the best overall productive performance, benefiting from a favorable combination between kernel number, thousand kernel weight (TKW), and the kernel-to-cob ratio. Hybrid P0900 also proved to be highly competitive, demonstrating a high productivity level and stable agronomic behavior. In contrast, hybrid P0216, although characterized by a high vegetative biomass weight, accumulated a lower kernel mass, resulting in a lower yield compared to the other two hybrids.

To support the validity of the observed differences among the analyzed hybrids regarding kernel weight per ear, a one-way ANOVA (Analysis of Variance) was performed. The test aimed to evaluate the significance of differences between means, based on a set of simulated data corresponding to the experimental mean, minimum, and maximum values recorded for each hybrid.

The result of the analysis indicated a probability value (p) of 0.0226 ($p < 0.05$), meaning that the differences observed in kernel weights among the three hybrids are statistically significant, with a 95% confidence level. This finding experimentally validates the field and laboratory observations, where DKC 5810 consistently showed the best performance in terms of individual kernel weight, followed by P0900, while P0216 recorded lower values.

In addition to the analysis of individual kernel weights, a statistical evaluation of the thousand kernel weight (TKW) was also conducted, an important indicator for estimating the biological yield potential of hybrids. Based on the mean values recorded both in the field and in the laboratory, data series were simulated for each hybrid. The ANOVA analysis applied to these series produced a highly conclusive result, with a probability value (p) of 0.0000087, significantly lower than the 0.05 threshold.

This value confirms that the differences between the TKW values of the three hybrids are not random but reflect distinct genetic and physiological characteristics. Hybrid DKC 5810 stood out with the highest TKW, followed by P0900, while P0216 recorded the lowest value—an aspect directly correlated with the total yield obtained per hectare.

Therefore, the statistical analysis supports the empirical validity of the observed morpho-productive differences and confirms that the thousand kernel weight is a relevant and differentiating indicator of genetic potential, particularly under minimum tillage technology conditions.

These comprehensive determinations contribute to shaping a detailed productive profile of the three hybrids, revealing clear differences in their efficiency in converting resources into economically important biomass. Furthermore, they emphasize the importance of selecting the appropriate hybrid based on the applied technology, climatic conditions, and farm objectives. The biometric and laboratory determinations reinforce field observations and substantiate the physiological and productive distinctions among the three hybrids under the minimum tillage system, providing a solid basis for interpreting hybrid behavior under real farm conditions.

CONCLUSIONS

Following the study conducted at the Iancu Ionuț Individual Enterprise farm, located in Lanurile, Constanța County, it was demonstrated that the application of minimum tillage technology in maize cultivation, combined with a controlled irrigation system and the selection of appropriate hybrids, can deliver competitive productive results even under challenging climatic conditions.

The three-year field experiment showed that reduced soil tillage, performed through a single combinator pass, allowed the formation of a suitable seedbed and supported uniform emergence, despite the cool springs and frequent rains recorded in April. The climatic regime analyzed during the study period revealed a consistent increase in average monthly temperatures, both during the growing season and in the cold months, accompanied by a clear

downward trend in precipitation. This climatic dynamic impacted crop behavior, particularly in the absence of additional water sources. Nevertheless, the application of sprinkler irrigation during four key maize developmental stages partially compensated for the water deficit and allowed the biological potential of the tested hybrids to be properly expressed.

The analyses performed in the field, on the farm, and in the phytotechnical laboratory provided a detailed picture of each hybrid's phenotypic behavior. Hybrid DKC 5810 stood out for its overall best performance, recording the highest values in most of the analyzed parameters: average kernel weight per ear, number of kernels, thousand kernel weight (TKW), and ultimately, yield per hectare. Hybrid P0900 also demonstrated excellent adaptability under intensive technology and irrigation conditions, showing consistent results. In contrast, P0216, despite its good vegetative development, recorded lower kernel mass, resulting in a lower yield compared to the other two hybrids.

The validity of the observed productive differences was further supported by the statistical analysis of experimental data. The ANOVA tests applied to kernel weight and TKW data highlighted statistically significant differences between the three hybrids, with p-values below the 0.05 threshold. These results confirm that the recorded yield differences are not random but rather reflect the genuine biological and adaptive potential of each genetic creation.

Based on these results, the continued application of the minimum tillage system is confidently recommended in areas with a climatic regime similar to that of Dobrogea, particularly in farms equipped with irrigation facilities. Hybrid selection should be made according to available resources and the technological objectives of each farming enterprise. Thus, DKC 5810 is recommended for farms with high inputs and irrigation, while P0900 can represent a viable and stable solution for moderate-input technologies. Careful climate monitoring, adaptive fertilization, and the application of phytosanitary treatments according to phenophases and pathogen pressure remain key factors in maximizing productive efficiency.

Furthermore, it is recommended to extend this type of study over a longer period and across other agricultural regions of the country, to validate the obtained conclusions and to develop precise regional recommendations within the framework of sustainable agriculture.

This study provides a valuable contribution to understanding the long-term impact of minimum tillage technology on maize cultivation under real farm conditions in a semi-arid area facing increasing climatic challenges. By integrating the analysis of hybrids' biological performance with adaptive crop management, the research offers a comprehensive and practical approach for optimizing sustainable agricultural production. The results highlight the importance of adopting conservation technologies in agriculture, which can contribute to natural resource preservation, cost reduction, and increased crop resilience to climatic variability.

ABSTRACT

The increasing urgency of climate resilience, resource efficiency, and ecological responsibility in agricultural systems has intensified the search for sustainable, low-cost, and adaptable technologies. This study presents a novel approach to biological production by transforming discarded mini glass-door refrigerators into automated, sensor-based silkworm incubation units. Designed at the intersection of agricultural innovation, environmental sustainability, and STEAM-based education, the project offers an integrated model that serves both pedagogical and technological functions. The study was implemented at Bodrum Science and Art Center, involving 12 gifted middle and high school students. The system utilized an Arduino UNO microcontroller combined with DHT11 temperature-humidity sensors, a real-time clock (RTC), mist generators, LED lighting, and ventilation components. The automated control system was coded and calibrated to maintain optimal environmental conditions across the 60-day life cycle of *Bombyx mori*. Each unit was assembled inside a repurposed mini refrigerator, thereby significantly reducing production costs and promoting e-waste recycling. Through this project, students engaged in hands-on learning through sensor integration, circuit building, algorithmic thinking, and biological observation. Pre- and post-assessments, observational rubrics, and learning journals were employed to evaluate their cognitive and technical progress. Quantitative findings revealed over a 40% improvement in students' abilities related to electronics, coding, and biological process management. The system maintained environmental stability within ± 1.5 °C for temperature and $\pm 4\%$ RH for humidity, effectively supporting all developmental stages of the silkworm. Qualitative data indicated enhanced student motivation, confidence, and collaborative problem-solving capacity. The prototype proved to be not only a viable incubation device for educational purposes but also a scalable, low-energy agricultural solution suitable for use in rural or resource-limited settings. Its open-source design allows for modular replication and adaptation to other biological applications such as seed germination, mushroom cultivation, or microgreen farming. This project demonstrates the power of combining circular economy principles with educational technology and ecological production. It contributes to the global discourse on sustainable agricultural innovation and provides a model for integrating engineering thinking into life science education. As such, it stands as a replicable example of how discarded technologies can be reimagined into tools for both learning and living systems management.

Keywords: Sustainable agriculture, recycling, silkworm, incubation system, Arduino, STEAM education, biological production.

INTRODUCTION

The accelerating climate crisis, biodiversity decline, and global push for sustainable development have elevated the urgency of finding innovative, ecologically responsible, and socially equitable solutions in agricultural systems. Agriculture, as one of the largest contributors to environmental degradation, faces unprecedented pressure to transition towards resilience, resource efficiency, and low-carbon production models (Georgescu, 2025). This transition requires not only technological innovation but also educational reform, as the next generation of learners must be equipped with the skills, values, and competencies needed to navigate a rapidly changing world. Within this dual imperative, integrating sustainability-driven practices into both agricultural innovation and educational frameworks becomes a powerful approach, particularly when linked to the principles of the circular economy (Nguyen et al., 2023; Laius, 2024).

The circular economy (CE) framework emphasizes reducing waste, reusing resources, and creating closed-loop systems in production and consumption. E-waste, one of the fastest-growing waste streams, highlights the magnitude of this challenge. Global e-waste generation exceeded 50 million metric tons in 2023 and is projected to reach 74 million tons by 2030 (Gupta, 2020). Beyond its hazardous impacts, e-waste embodies untapped opportunities for creative reuse, especially in educational contexts where discarded materials can be repurposed into learning tools. Studies increasingly show that upcycling and reusing e-waste in educational projects fosters not only environmental literacy but also technical and problem-solving skills among students (Nikoloudakis, 2025; Souza et al., 2025). For example, Anand (2023) demonstrated that embedding e-waste reuse in design education cultivates creativity, while Vyas et al. (2023) showed that working with discarded electronics enhances computational thinking and systems-level awareness. In similar research, Khajuria (2025) revealed that e-waste projects embedded in science classrooms boost both sustainability awareness and collaborative learning. Thus, e-waste repurposing in educational contexts is increasingly framed as a pedagogical strategy aligned with the United Nations Sustainable Development Goals (SDGs).

Agriculture is a particularly fertile ground for integrating circular economy principles, as resource demands and waste outputs remain central to global sustainability debates. The Food and Agriculture Organization (FAO) has warned that agricultural systems must cut greenhouse gas emissions by at least 20% by 2035 while simultaneously addressing global food security (Yue et al., 2023). Sericulture, the rearing of the domesticated silkworm (*Bombyx mori*), is an illustrative case within this debate, as it combines cultural, ecological, and economic significance. Long practiced in Asia, Africa, and Southern Europe, sericulture remains a vital rural livelihood activity. Yet, it is highly vulnerable to environmental fluctuations, particularly temperature and humidity changes that directly affect silkworm growth and cocoon production (Manjunatha & Neelagar, 2018). Conventional sericulture methods often require precise environmental control that is both energy-intensive and costly, making it less accessible in resource-limited settings. This vulnerability underscores the importance of developing affordable, adaptive incubation systems capable of maintaining stability under varying conditions.

Digital and open-source technologies are increasingly being leveraged to address such challenges. Arduino-based microcontrollers, low-cost sensors, and IoT-enabled monitoring systems are now central to agricultural innovation (Prabowo & Irwanto, 2023; Nannim et al., 2025). Duque-Torres et al. (2018) demonstrated the viability of Raspberry Pi systems for automated egg incubation, while Manjunatha and Neelagar (2018) introduced Arduino-based IoT prototypes to regulate silk-rearing environments. More recently, artificial intelligence and machine learning have been employed to enhance sericulture productivity through real-time data analytics and automated control (AI-driven Sericulture, 2025). These advances represent

a broader movement toward precision agriculture, where low-cost digital tools reduce inefficiencies and increase sustainability. Within this context, repurposing consumer appliances such as discarded mini glass-door refrigerators into silkworm incubation units offers a unique convergence of circular economy, technological innovation, and agricultural adaptation.

At the same time, education is increasingly recognized as a critical arena for embedding sustainability and technological literacy. Project-based STEAM (Science, Technology, Engineering, Arts, and Mathematics) learning approaches are particularly effective in cultivating both technical competencies and socio-environmental awareness. Research indicates that hands-on projects involving Arduino and other open-source hardware foster algorithmic thinking, creativity, and teamwork (Oh, 2025; Barradas, 2024). Marín-Marín et al. (2024) found that robotics-based STEAM programs significantly increased motivation and problem-solving capacity among secondary students, while Nannim et al. (2025) demonstrated that Arduino projects improve persistence and collaborative learning. Similarly, Oh (2025) showed that integrating Arduino-powered projects into environmental science education enhanced both self-efficacy and critical thinking. Bibliometric analyses confirm that Arduino has become a cornerstone in science and engineering education, bridging electronics, coding, and real-world problem-solving (Prabowo & Irwanto, 2023).

Integrating sericulture into STEAM education provides an innovative model for uniting biological science, engineering design, and sustainability principles. The life cycle of *Bombyx mori* offers a tangible biological process that students can observe and influence through technological interventions. By constructing automated incubation systems, learners engage in sensor integration, circuit design, coding, algorithmic calibration, and biological monitoring—all within the framework of a real-world ecological challenge. Such activities translate abstract sustainability principles into concrete practices, operationalizing systems thinking and fostering eco-technological innovation (Souza et al., 2025; Khajuria, 2025). Importantly, engaging students with discarded technologies promotes the mindset that waste materials can be reimaged into valuable tools, aligning educational practices with circular economy imperatives (Nguyen et al., 2023).

In addition to fostering technical competencies, such projects address motivational and affective dimensions of learning. Numerous studies indicate that project-based STEAM education increases student motivation, confidence, and engagement (Oh, 2025; Barradas, 2024). Word-cloud analyses of student reflections often reveal recurring themes of collaboration, creativity, and persistence (Souza et al., 2025). These outcomes are critical given the growing emphasis on “future-ready” skills, which extend beyond disciplinary knowledge to include adaptability, resilience, and collective problem-solving. When coupled with sustainability-driven projects, the pedagogical impacts extend even further, empowering students as agents of environmental and technological innovation (Marín-Marín et al., 2024; Laius, 2024). The global discourse on sustainability also emphasizes scalability and transferability. Repurposed incubation systems have potential applications beyond silkworm rearing, including seed germination, mushroom cultivation, and microgreen farming (Duque-Torres et al., 2018; Yue et al., 2023). Each of these practices requires precise control of environmental conditions, which can be achieved through similar sensor-based technologies. The modularity and open-source nature of Arduino systems make them particularly well-suited for adaptation across diverse contexts. Furthermore, aligning such projects with circular economy practices enhances their impact, as they simultaneously address issues of resource efficiency, waste minimization, and educational innovation (Nikoloudakis, 2025).

Despite the growing literature on sustainability, educational innovation, and agricultural adaptation, there remains a gap at the intersection of these fields. Few studies have explicitly combined circular economy principles with STEAM education and agricultural technology. Most agricultural innovations focus narrowly on productivity, while educational projects often

lack ecological grounding. This disconnect limits the transformative potential of both fields. By bridging these domains, the present study addresses an important research gap, demonstrating how discarded technologies can be repurposed into low-cost agricultural solutions while simultaneously serving as powerful educational tools. Specifically, it showcases the design and implementation of an automated silkworm incubation system developed at Bodrum Science and Art Center, involving 12 gifted middle and high school students. The project contributes to global debates on sustainability in three ways: first, by operationalizing circular economy principles through e-waste repurposing; second, by providing a scalable model for low-cost agricultural incubation; and third, by integrating engineering practices into life science education to enhance student learning outcomes.

In summary, this study presents an integrated approach to sustainable agricultural innovation and STEAM education by transforming discarded mini refrigerators into Arduino-controlled silkworm incubation units. It aligns with global sustainability priorities, educational reform agendas, and the growing need for scalable, low-cost technologies in resource-limited settings. By situating itself within the literature on circular economy, sericulture innovation, and STEAM pedagogy, it contributes both theoretically and practically to the discourse on how waste can be reimagined as a resource for learning and living systems management.

MATERIAL AND METHOD

This study was conducted at the Bodrum Science and Art Center (Bodrum BİLSEM) in Türkiye, within the institution's biology and technology laboratories. The project was designed to both construct a functional, sustainable silkworm incubation system from discarded appliances and to evaluate the educational benefits for gifted students engaged in STEAM-based learning.

Participants

The participants included 12 gifted middle and high school students (aged 12–17) enrolled at Bodrum Science and Art Center. Recruitment was based on voluntary participation, and parental consent was obtained for all students. Prior to the study, participants had limited exposure to electronics, coding, and biological production processes, which allowed for a more accurate assessment of their cognitive and technical progress throughout the project.

Hardware Components

The incubation systems were developed by repurposing discarded glass-door mini refrigerators. Each incubator was retrofitted with low-cost, open-source components:

- Microcontroller: Arduino UNO R3
- Sensors: DHT11 temperature–humidity sensors, RTC (Real Time Clock) module
- Environmental control units: Ultrasonic mist generators for humidity regulation, LED lights for photoperiod control, and DC fans for air circulation and ventilation
- Data interface: LCD display for local monitoring and serial communication for computer-based data logging
- Power supply: 12V adapter-supported energy unit
- Chassis: Insulated body of a recycled mini refrigerator

Software and Programming

Students used the Arduino IDE to develop control algorithms that continuously monitored temperature and humidity levels. The system was programmed to automatically activate mist generators and fans when sensor values deviated from pre-defined thresholds. Calibration was carried out to ensure that:

- Temperature was maintained within ± 1.5 °C of the set point,
- Relative humidity (RH) was controlled within $\pm 4\%$.

The RTC module provided real-time scheduling, enabling periodic regulation of environmental conditions. Data were displayed in real-time on LCD panels and simultaneously logged via serial port connections for subsequent analysis.

Experimental Procedure

The experimental phase encompassed the full 60-day life cycle of *Bombyx mori*. Approximately 100 silkworm eggs were placed in each incubation unit, and their development was tracked across the larval, pupal, and cocoon stages. Environmental parameters were monitored continuously, while students recorded biological observations daily. These included molting phases, larval growth rates, pupation success, and cocoon formation. Observations were supplemented with photographs, videos, and learning journals maintained by the students.

Educational Data Collection

To assess the pedagogical impact of the project, a mixed-methods evaluation framework was employed:

1. Pre- and post-assessments: Standardized tests measured knowledge and skills in electronics, coding, and biological systems management.
2. Observational rubrics: Teacher–researchers documented student performance in problem-solving, collaboration, and technical task execution during laboratory sessions.
3. Learning journals: Students recorded reflective narratives, providing qualitative insights into motivation, confidence, and conceptual understanding.

Statistical and Qualitative Analysis

- Quantitative data from pre- and post-assessments were analyzed using paired-sample t-tests, with significance set at $p < 0.05$.
- Observational rubric scores were summarized using descriptive statistics (means, standard deviations, and percentages).
- Qualitative data from learning journals were coded using content analysis, allowing the identification of emergent themes such as motivation, confidence, collaboration, and scientific curiosity.

Ethical Considerations

The study adhered to ethical research standards for both human participants and animal welfare. Informed consent was obtained from all students and their guardians. All data were anonymized prior to analysis. The rearing of silkworms complied with accepted practices for maintaining *Bombyx mori*, ensuring that no aspect of the experimental process compromised animal welfare.

RESULTS AND DISCUSSION

The findings of this study are presented in two categories: (a) the technical performance of the repurposed incubation system in supporting the complete life cycle of *Bombyx mori* and (b) the educational outcomes achieved by participating students. Quantitative results are supported by tables and statistical analysis, while qualitative outcomes are illustrated through thematic interpretation of student reflections. The incubation units maintained stable environmental conditions throughout the 60-day rearing period. Average temperature remained within the targeted range (24–28 °C), with a mean of 26.1 ± 0.8 °C, while relative humidity was kept within $73.6 \pm 2.7\%$, aligning with the set tolerance of $\pm 4\%$. Photoperiod was precisely controlled by LED lighting (12:12 h cycle), and ventilation systems effectively prevented CO₂ accumulation and mold formation. Cocoon formation success reached 93%, with only 5% larval mortality, reflecting the biological adequacy of the system.

Table 1. Environmental Parameters Maintained Across the 60-Day Silkworm Life Cycle

Parameter	Target Range	Mean Value $\pm$ SD	System Accuracy	Biological Outcome
Temperature (°C)	24–28	26.1 ± 0.8	± 1.5 °C	Optimal growth
Humidity (%)	70–85	73.6 ± 2.7	$\pm 4\%$ RH	High cocoon yield
Photoperiod	12/12 h	Precisely timed	± 1 min/day	Normal molting
Ventilation	Real-time	Stable airflow	Automated	

Figure 1. illustrates the temporal stability of temperature and humidity across the full life cycle. Despite minor fluctuations, all values remained within the biological tolerance zone.

Educational Outcomes

Quantitative Learning Gains

Statistical analysis of pre- and post-test results demonstrated significant improvements across all skill domains.

Electronics and circuit design: Average scores increased by 42% ($t(11) = 5.12$, $p < 0.01$).

Programming and algorithmic thinking: Average scores improved by 47% ($t(11) = 5.94$, $p < 0.01$).

Biological process management: Average scores rose by 38% ($t(11) = 3.62$, $p < 0.05$).

Table 2. Pre- and Post-Test Results Across Skill Domains

Domain	Pre-Test Mean ± SD	Post-Test Mean ± SD	% Improvement	t(11)	P Value
Electronics & Circuits	41.3 ± 6.2	58.6 ± 7.5	+42%	5.12	<0.01
Programming & Coding	36.8 ± 7.1	54.1 ± 6.9	+47%	5.94	<0.01
Biological Process Management	44.5 ± 5.9	61.2 ± 8.0			

Figure 2. visually compares pre- and post-test performance, highlighting consistent growth across all measured domains.

Qualitative Learning Gains

Content analysis of learning journals identified three dominant themes:

Motivation and Confidence – Students reported a stronger sense of competence in handling coding and electronics.

Collaboration and Problem-Solving – Team-based troubleshooting reinforced cooperative learning.

Ecological Awareness – Learners expressed an enhanced understanding of recycling and sustainable innovation.

Table 3. Emergent Themes from Qualitative Analysis

Theme	Frequency (%)	Representative Student Quote
Motivation & Confidence	75%	“I never thought I could code, but now I can design systems that keep animals alive.”
Collaboration	67%	“When the mist generator failed, we solved it together as a team.”
Ecological Awareness	58%	“Using an old fridge to raise silkworms made me realize waste can become useful again.”

Figure 3. Depicts the relative frequency of recurring themes extracted from student reflections, confirming the prominence of motivation, teamwork, and sustainability awareness.

The findings demonstrate that the repurposed incubation units successfully supported the complete biological cycle of *Bombyx mori*, with outcomes comparable to conventional laboratory incubators, while significantly reducing costs and energy use. At the same time, students exhibited substantial cognitive and technical gains, with quantitative improvements of over 40% in electronics, coding, and biological management skills, complemented by qualitative evidence of enhanced motivation, collaboration, and ecological responsibility.

DISCUSSION

The findings of this study demonstrated that the repurposed mini glass-door refrigerators, equipped with Arduino-based sensors and automated controls, maintained environmental stability within ± 1.5 °C for temperature and $\pm 4\%$ RH for humidity throughout the 60-day life cycle of *Bombyx mori*. This level of precision is comparable to or exceeds that reported in prior sericulture automation studies (Manjunatha & Neelagar, 2018; Duque-Torres et al., 2018). The success of the system in supporting all developmental stages of the silkworm

illustrates its technical robustness and viability as a low-cost incubation solution, particularly for rural or resource-limited contexts. In addition, the project achieved significant educational outcomes, with students showing over 40% improvement in electronics, coding, and biological management skills. These results validate the hypothesis that circular economy-driven educational projects can simultaneously generate tangible technological solutions and pedagogical benefits.

When compared to previous research, several unique contributions emerge. IoT-based sericulture systems, such as those described by Manjunatha and Neelagar (2018), typically rely on purpose-built hardware and energy-intensive infrastructures, which limit accessibility in low-income regions. Similarly, Duque-Torres et al. (2018) demonstrated Raspberry Pi-based incubation systems but did not address the scalability of e-waste repurposing. By contrast, the present project combined precision environmental control with the creative reuse of discarded refrigerators, thereby lowering costs and advancing circular economy principles (Nguyen et al., 2023). The project not only achieved biological effectiveness but also modeled how e-waste can be transformed into functional agricultural devices, echoing findings from recent educational sustainability studies (Khajuria, 2025; Nikoloudakis, 2025).

The educational dimension also warrants deeper discussion. Previous research has consistently shown that Arduino and other open-source hardware enhance STEM learning, critical thinking, and persistence (Prabowo & Irwanto, 2023; Marín-Marín et al., 2024). Oh (2025) reported that students engaged in Arduino-based projects showed heightened motivation and confidence, while Barradas (2024) emphasized improvements in teamwork and algorithmic reasoning. Our study supports and extends these findings by embedding Arduino projects within a sustainability and life-science context, demonstrating that when technical projects are coupled with ecological purpose, learning outcomes extend beyond cognitive gains to include eco-centric values and systems thinking. The reflective journals and word cloud analyses revealed that students repeatedly referenced sustainability, creativity, and resilience—keywords aligned with 21st-century competencies (Souza et al., 2025). This suggests that integrating circular economy themes into STEAM education provides a stronger motivational framework than purely technical projects.

From a sustainability perspective, the project aligns with the growing discourse on circular economy applications in agriculture. While most studies on agricultural innovation emphasize productivity gains (Yue et al., 2023; Georgescu, 2025), fewer focus on resource reuse and waste minimization. The present study contributes to filling this gap by showcasing how discarded technologies can be reimaged as agricultural assets. This resonates with the argument by Laius (2024) that educational systems must embrace ecological responsibility as a pedagogical goal. Furthermore, the prototype's scalability suggests potential applications in seed germination, mushroom farming, and microgreen cultivation (Duque-Torres et al., 2018). These possibilities highlight its role not just as a student project, but as a practical agricultural solution with broader implications.

Nevertheless, several limitations must be acknowledged. First, the study was conducted with a relatively small cohort of 12 students, which may limit the generalizability of educational findings. Although pre- and post-assessments indicated significant cognitive and technical improvements, further validation with larger and more diverse populations is warranted. Second, while the incubation system effectively supported silkworm growth under controlled laboratory-like conditions, field trials in rural environments with fluctuating power and humidity levels are necessary to fully establish resilience and scalability (Manjunatha & Neelagar, 2018). Third, although the system reduced costs by repurposing e-waste, the availability of suitable discarded refrigerators may vary geographically, requiring additional design adaptations. Future studies should explore modularity and design optimization for broader adoption.

Another important dimension relates to policy and global agendas. The United Nations SDGs emphasize sustainable production, quality education, and responsible consumption (UNESCO, 2024). By integrating circular economy strategies with STEAM pedagogy, this project provides a replicable model that directly supports these goals. Nikoloudakis (2025) has argued that educational practices embedding sustainability create long-term behavioral shifts, while Anand (2023) demonstrated that e-waste upcycling projects foster eco-design mindsets among youth. The current project validates these claims, showing that when learners are empowered to transform waste into tools for life science innovation, they embody both the spirit and practice of sustainability.

In conclusion, this discussion highlights the dual significance of the present study. Technologically, it demonstrates that low-cost, e-waste-based incubation systems can rival or outperform conventional setups in maintaining biological stability. Pedagogically, it confirms that embedding circular economy practices into STEAM education produces not only measurable skill gains but also ecological consciousness. This combination of ecological, technological, and educational value strengthens the project's contribution to the global discourse on sustainable agricultural innovation. By situating itself at the intersection of circular economy, sericulture, and STEAM pedagogy, it provides a compelling model for future research and practice.

CONCLUSIONS

This study demonstrated the feasibility and educational impact of transforming discarded mini glass-door refrigerators into automated silkworm incubation units. By integrating low-cost, open-source electronics with circular economy principles, the project achieved a dual purpose: supporting the complete biological life cycle of *Bombyx mori* under controlled conditions, and fostering interdisciplinary learning among gifted middle and high school students. The findings confirmed that such repurposed systems can maintain stable environmental parameters—temperature within ± 1.5 °C and humidity within $\pm 4\%$ RH—comparable to conventional incubators, while significantly reducing energy consumption and operational costs. The high cocoon formation success rate (93%) validated the technical robustness of the system, providing a sustainable alternative for small-scale sericulture and broader biological applications.

Beyond technical outcomes, the educational dimension of this project was equally significant. Quantitative results demonstrated over 40% improvement in students' skills in electronics, coding, and biological process management, while qualitative reflections highlighted increased motivation, collaboration, and ecological awareness. These results resonate with prior literature emphasizing the role of STEAM education in fostering problem-solving, creativity, and socio-scientific reasoning (Nguyen et al., 2023; Malecha, 2020). Moreover, the incorporation of e-waste repurposing into a hands-on learning framework positions this study within emerging discourses on circular economy education, where sustainability principles are not only taught but enacted through authentic practice (Chatzopoulos et al., 2023).

The contribution of this research lies in its multidimensional novelty. While prior studies have explored automation in sericulture (Duque-Torres et al., 2018; Manjunatha et al., 2018), or the integration of Arduino-based systems in agriculture, none have simultaneously advanced environmental sustainability, biological production, and STEAM pedagogy through repurposed technologies. This work therefore bridges a critical gap between technological innovation and educational transformation, offering a replicable model for educators, researchers, and practitioners across multiple fields.

Several implications emerge from this study:

1. For Education – Schools and science centers can leverage discarded appliances as learning platforms, reducing costs while enriching STEAM curricula with sustainability-focused projects.

2. For Sustainable Agriculture – Low-energy, modular incubation units can serve rural or resource-limited communities, supporting diverse applications such as seed germination, mushroom cultivation, and insect rearing.

3. For Policy and Practice – The model supports global sustainability agendas, aligning with SDGs 4 (Quality Education), 12 (Responsible Consumption and Production), and 13 (Climate Action). Integration into educational policy frameworks could promote systemic adoption of circular economy practices in schools.

Nonetheless, limitations must be acknowledged. The study was conducted with a relatively small cohort of students ($n = 12$) and within a single institutional context, which may limit generalizability. Additionally, while system performance was robust, long-term durability across multiple rearing cycles and large-scale replication were not assessed. Future research should explore:

- Comparative studies between traditional and repurposed incubation systems,
- Integration of renewable energy sources (e.g., solar panels) to further reduce environmental impact,
- Development of IoT-enabled features for remote monitoring and AI-based predictive control,
- Longitudinal studies on the sustained educational impact of circular economy-based STEAM projects.

In conclusion, this study illustrates the transformative potential of reimagining discarded technologies as tools for both learning and ecological production. It demonstrates that innovation does not always require new resources; rather, it can emerge from creatively reusing what has been discarded. By bridging sustainability, education, and technology, the project provides a replicable blueprint for cultivating not only silkworms, but also a new generation of learners capable of managing living systems with ingenuity, responsibility, and ecological consciousness.

APPENDICES

Appendix A. Sample Items from Pre- and Post-Tests

The pre-/post-tests were developed to measure students' progress in three domains: electronics & circuits, programming & coding, and biological process management. Each domain included 10 multiple-choice questions and 2 short-answer items. Below are illustrative examples:

- Electronics & Circuits:
 1. Which of the following components is used to regulate airflow in an incubation chamber?

a) LED, b) Resistor, c) DC Fan, d) RTC Module
 2. Calculate the total resistance of two resistors connected in parallel, one 100 Ω and the other 200 Ω .
- Programming & Coding:
 1. In Arduino IDE, which function is continuously executed after setup()?

a) loop(), b) start(), c) repeat(), d) continue()
 2. Write a short code snippet that activates a fan when temperature exceeds 28 °C.

Biological Process Management:

1. What is the optimal temperature range for *Bombyx mori* larvae development?
2. During which larval instar is mulberry consumption the highest?

Appendix B. Observational Rubric

Teachers and researchers assessed student performance during laboratory sessions using the following rubric. Scores ranged from 1 (Poor) to 5 (Excellent).

Dimension	1 (Poor)	3 (Satisfactory)	5 (Excellent)
Problem-Solving	Unable to identify or attempt solutions	Partially identifies issues and attempts solutions	Independently identifies and resolves technical/biological issues
Collaboration	Rarely contributes to group work	Contributes occasionally, limited interaction	Actively engages, facilitates teamwork, constructive feedback
Technical Skill Execution	Frequently requires assistance	Performs tasks with partial independence	Fully executes tasks independently and accurately
Safety & Laboratory Ethics	Disregards safety and care instructions	Follows most guidelines, minor lapses	Consistently adheres to safety and ethical standards

Appendix C. Sample Arduino Code Snippets

The following excerpts illustrate key elements of the Arduino control algorithm used in the incubation units.

Appendix D. Learning Journal Prompts

Students were instructed to keep reflective journals throughout the 60-day experiment. The following guiding questions were provided:

1. Describe one technical challenge you faced today and how you attempted to solve it.
2. What did you learn about silkworm biology from today's observations?
3. How did working with sensors, circuits, and coding affect your confidence in STEM subjects?
4. Did this project change how you think about recycling and sustainability? How?
5. Reflect on how collaboration with peers influenced your learning experience.

Appendix E. Ethical Consent Form Excerpt

An excerpt from the parental consent form is provided to illustrate compliance with ethical standards:

"I consent to my child's participation in the research project titled 'Sustainable Incubation Systems through Repurposed Appliances for Silkworm Rearing.' I understand that all data collected will be anonymized, used solely for research purposes, and that participation is voluntary. My child may withdraw at any time without penalty."

SOME TAXONOMIC, ECOLOGICAL AND ETHNO-ENTOMOLOGICAL DATA ON THE LOCUSTS (ORTHOPTERA) OF THE HABITATS OF VLORA

ABSTRACT

The Order Orthoptera belongs to the Class of Insects. This study presents taxonomic, ecological, and ethno-entomological data of species of the Order Orthoptera in various habitats of the Vlora area. Expeditions were conducted to collect biological material at 4 stations in the area, from 2022-2023. Our study presents a taxonomic analysis of the species, genera, and families of the specimens we encountered in these habitats, as well as some ecological considerations of the behavior of these species, based on the taxonomic analysis. We identified 33 species and 4 families of the order Orthoptera; keys and similar literature for this area were used for species identification. From the taxonomic analysis, the Acrididae family represents the highest biodiversity of Orthoptera species, with 19 species, followed by the Tettigoniidae family with 11 species. Regarding the stations, we found the highest number of species in Lepenica with 16 species, and fewer species on Zvernec Island with 12 species. The habitats in Lepenica offer optimal conditions for these species. Additionally, in this study, we took an ethno-entomological approach, based on semi-structured interviews with the local community (N=25) regarding their perceptions, attitudes, and various uses of insects, including locusts.

Keywords: Biodiversity, Ethno-entomology, Orthoptera, Perceptions, Taxonomy

INTRODUCTION

The order Orthoptera is part of the class Insecta, and includes insects known as grasshoppers (Bidau, 2014). The order Orthoptera is divided into two main groups: Caelifera (grasshoppers with short antennae) and Ensifera (grasshoppers with long antennae) (Leubner et al., 2017).

Orthoptera are terrestrial insects that are known for their hind legs, which they use for jumping, and their ability to produce sounds (stridulation) (Hoell, 1998; Subashaj et al., 2024).

These insects, being present in many terrestrial environments, exhibit a wide diversity (Harche et al., 2024; Yadav & Kumar, 2017). The wings of species of the Order Orthoptera vary from more fully developed to completely absent (wingless Orthoptera) (Naskrecki, 2013). In addition to being insects used as ecological and biological bioindicators of environmental quality, they also exhibit behavior as pests of agricultural crops (Pudasaini & Dhital, 2022; Begna & Fielding, 2003; Zhang et al., 2019; Dakhel, et al., 2020).

In the southern part of Albania, research on Orthoptera has been scarce and is referred to by publications before World War II by foreign researchers, and before the 1990s by local and foreign researchers (Murraj et al., 1970; Salfi, 1937). In recent years, there has been interest in studying the Orthoptera of Albania by foreign researchers, in some mountainous areas of

Albania that are potentially preferred for these species, where new species have also been referred (Lemonnier- Darcemont et al., 2015; Gellért, 2016; Rabl & Kunz, 2018).

We have conducted an ethno-entomological assessment of insects and grasshoppers, in particular in the Vlora area. Studies of an ethnobiological nature in our country have been carried out since the 19th century, mainly in the field of ethnobotany, and in various areas in Albania (Saraçi & Damo, 2021; Bajrami, 2023) while studies of a local ethnozoological nature are rare, and have mainly focused on bees, mammals and birds (Ndoja, 1964; Trajçe et al., 2019; Stara et al., 2022).

As a subfield of ethnozoology, ethno-entomological studies are related not only to the degree of knowledge in the biocultural plane of insects but also to possible protective and conservation practices: by using knowledge of cultural knowledge and practices about insects, they serve as a guiding compass in policies related to biodiversity or to mitigate the impact of today's challenges, such as climate change (Wolverton, 2013; Wolverton et al., 2014; Alves, 2018).

Our study refers to the taxonomic, ecological and ethnoentomological analysis of Orthoptera species at several stations in the Vlora area, which is carried out within the framework of doctoral studies in the field of Biology, at the University of Tirana, and with the consultations and unstinting assistance of French colleagues Michèle Lemonnier-Darcemont and Christian Darcemont, specialists of this order in our country and in the Balkans.

MATERIALS AND METHODS

The collection of species of the Order Orthoptera was carried out during the period 2022 – 2023, mainly during the summer and autumn months. Expeditions were carried out at several stations of four ecosystems of the Vlora area: Lepenice, Sevaster, Ploc and Zvernec Island (Figure 1). The collection of material was carried out in the morning between 09.00 and 14.00 depending on climatic conditions. Aerial entomological nets (NET) were used to collect species which were stored in bottles with ether (to preserve color) (Colas, 2000, Halimi et al., 2024). For each station, the date, location, coordinates (GPS Coordinates), altitude above sea level and vegetation were determined.

For taxonomic identification, the collected species were observed with a Stereomicroscope (Perfix Sciences), based on external characteristics and keys and literature from countries bordering Albania, which have habitats similar to the Study Area (Willemse et al., 2018; Lemonnier – Darcemont et al., 2018) were used as well as previous publications on the Order Orthoptera of Albania (Csiki, 1922; Subashaj et. al 2024).

The ethno-entomological expeditions were carried out in the Vlora region in two phases with two different groups: from 17.07.2023 to 20.07.2023 and from 24.06.2024 to 27.06.2024. In the first phase of the expeditions, three working hypotheses were put forward: H1: What are the perceptions of locusts among the inhabitants of the Vlora region? H2: What are the attitudes towards locusts and insects in general? H3: The ways of using insects as cultural services. Respondents were asked to rate from 1 (very good) to 5 (very bad).

In the second phase, residents under 30 years of age were interviewed and three other hypotheses were formulated: H1: Do perceptions about locusts change based on the age of the respondents? H2: Is there a relationship between perceptions, hostile attitudes and the lack of cultural services of locusts but also insects in general? H3: What is the correlation between the level of knowledge and hostile attitudes? In total, the number of respondents was N=25 where the majority of respondents were male. The minimum age of the respondents was 16 years old and the maximum was 68 years old.

RESULTS AND DISCUSSION

Our study was conducted in the Vlora area, located in the southwestern part of the country, with a Mediterranean climate that offers very mild winters and hot summers, and with a variety of habitats (Figure 1). The coordinates of the stations where the biological material of the 4 habitats of the study area was collected are presented as follows (Table 1):

Table 1. Species collection stations by station

No.	Habitat	Station coordinates	Altitude (m)
1	Lepenice	40.306210, 19.610822	770
	Lepenice	40.304710, 19.607364	850
	Lepenice	40.298244, 19.611422	990
	Lepenice	40.295944, 19.608383	1150
	Lepenice	40.293931, 19.604014	1230

31	<i>Paratettix meridionalis</i> Rambur, 1838	+			
4	Family Gryllidae Laicharting, 1781				
32	<i>Oecanthus pellucens</i> Scopoli, 1763	+			
33	<i>Gryllus campestris</i> Linnaeus, 1758	+			

From the taxonomic analysis of the distribution of the number of species and the species frequency by families, it results that the Acrididae family represents the highest number of species, with 19 species of the total number of species and with a species frequency of 57.57%. The Tettigoniidae family is represented by 11 species and with a species frequency of 33.33%, the Gryllidae family with 2 species and with a species frequency of 6%. The Tetrigidae family is represented by only 1 species and with a species frequency of 3% (Table 3, Figure 2).

From these data we can say that the species of the Acrididae family represent a high valence of the biological cycle, for the 4 habitats of the area under study. However, more extensive research should be carried out to reach scientific conclusions.

Table 3. Distribution of number of species and species frequency by families

No.	Family	Number of species	Species frequency (%)
1	Acrididae	19	57.57%
2	Tettigoniidae	11	33.33%
3	Gryllidae	2	6 %
4	Tetrigidae	1	3 %

Figure 2. Distribution of the number of species by family

From the analysis of species of the Order Orthoptera in the ecosystems according to the stations of the study area Lepenice, Sevaster, Ploc and Zvernec Island (Figure 3, Table 4), it results that the Lepenice station has the highest number of species, with 16 species of the total number of species and with a species frequency of 48.48%. The Zvernec Island station with 12 species and with a species frequency of 36.36%, the Ploc station with 10 species and with a species frequency of 30.30%, the Sevaster station with 9 species and with a species frequency of 27.27%.

From the above data, we can say that the habitats of the stations where we conducted the collection in Lepenice and Zvernec Island offer suitable habitats for species of the Order Orthoptera. More in-depth studies are recommended to reach more complete scientific conclusions.

Table 4. Distribution of species number and species frequency by stations

No.	Station	Number of species	Species frequency (%)
1	Lepenice	16	48.48 %
2	Zvernec Island	12	36.36 %
3	Ploc	10	30.30 %
4	Sevaster	9	27.27 %

Figure 3. Distribution of the number of species by stations

From the ethno-faunal analysis in the first phase of the expedition (July 2023) regarding locusts, as expected, the perceptions of the residents were mainly negative (3.4) and the level of their knowledge was low. It also resulted that the use of poisonous chemicals was common; regarding the cultural services of insects, including locusts, a fact unnoticed in the tradition of the area but also in Albanian culture, none resulted.

In the second phase of the expedition (June 2024) interviews were conducted with individuals under the age of 30. Their perceptions were less negative (3.2) compared to the first group but their level of knowledge continued to be low; the use of chemicals was not supported and as expected, no cultural services of insects, including locusts, were recorded.

CONCLUSIONS

Our study presents a taxonomic, ecological and ethno-entomological analysis of the entomofauna of Orthoptera in the Vlora area in 4 habitats: Lepenice, Sevaster, Ploc and Zvernec Island.

The Acrididae family presents the highest species biodiversity in these habitats with 19 species and species frequency 57.57%, presenting a high valence for the habitats of the area under study.

The Lepenice and Zvernec Island stations result in the highest biodiversity, respectively with 16 and 12 species, and species frequency 48.48% and 36.36%. These stations offer suitable habitats for species of the Order Orthoptera, influenced by isolated human activity, as they are conservative areas, and with little anthropogenic activity to the detriment of habitats.

The ento-faunistic assessment shows that there is a connection between negative perception and low level of knowledge. The rating scale ranges from 3.4 (averagely bad). There is also a hostile attitude towards insects, especially species of the Order Orthoptera, which, as expected, does not serve their recognition on the biological and cultural level and, consequently, their conservation is endangered. Regarding the cultural services of insects by the inhabitants, it did not result except for honey bees.

We found that age is a variable that takes on weight, based on life experience, older ages have a more hostile attitude while younger ages, also due to an increasing environmental sensitivity, although they appeared more indifferent and with a low level of knowledge, are not as hostile (3.2) compared to the first group. Worrying is the fact that there is a correlation between a low level of knowledge and a negative perception of insects and especially locusts, as pests in particular. These perceptions directly affect the appropriate ways of conserving insects and the services they provide (Duffus et al., 2021).

ACKNOWLEDGEMENTS

The authors thank the support of the University of Tirana, within the framework of the "UT-Research, Excellence and Innovation KEI-2023" Program.

ABSTRACT

Dairy farming in Bosnia and Herzegovina is a key branch of agriculture, but it faces numerous challenges within its value chain. Although the sector has significant potential, there are problems such as low efficiency, market fragmentation and informal business relationships. This paper analyses the structure of the value chain in dairy farming, identifies key actors and production phases, and proposes measures to improve the efficiency and competitiveness of the sector. The following methods were used in the research: survey method, analysis and synthesis method, description method and comparison method. As a challenge in managing and establishing a more efficient market chain, the question arises of how to include small producers in modern market chains. Milk production should be primarily focused on cheaper and higher quality products. This is possible with new technologies, especially in the way animals are kept and treated, nutrition, hygiene, etc. Preference should be given to systems that make maximum use of cheaper inputs - fodder from grassland and arable crop rotation. The intensity of milk production per head should be contrasted with the intensity, i.e. profit per unit of area, i.e. invested capital. The basis for the development of milk production should be on voluminous fodder. Milk production on smaller farms should gradually take on characteristics – organic, indigenous. In the future, greater importance should be given to longer-lasting dairy products and products with added value. Therefore, traditional production should be preserved and measures should be taken to standardize and protect the geographical origin and originality of some types of cheese. Cheese and cream are mainly sold at the markets as traditional domestic products.

Keywords: Dairy sector, Value chain, Milk production, Small farmers

INTRODUCTION

Dairying is one of the important branches of agricultural production in Bosnia and Herzegovina, with significant potential for increasing the country's economic stability. The tradition in this sector is quite long and there are many "domestic" brands, which are poorly used.

Unfortunately, the sector faces numerous challenges, from problems with low productivity, lagging infrastructure, to low competitiveness on international markets. On the other hand, the import of finished milk products is growing year by year. According to research by Krilić et al. (2022), although dairying is a strategically important sector for BiH, the sector suffers from low efficiency and weak coordination among actors in the value chain, which negatively affects its development. A similar conclusion was reached by Vuković (2019), who in his work analyzes the competitiveness of the milk sector in BiH and points to very low competitiveness, which is reflected in low efficiency and poor organization. This has been especially pronounced in the last few years, when there was a large imbalance in the purchase prices of raw milk and the prices of finished products in retail stores.

According to USDA data from 2020, the average milk production per cow in BiH is 2,612 liters, which is significantly below the EU average, while more than 70% of farms in BiH are engaged in production with less than 5 cows (USDA, 2020). These data show the low productivity of dairy farms, the small number of cows on them, which on the other hand prevents the use of modern technologies (Krstić, 2018). Due to all of the above, many milk producers sell their products on local markets, while they are unable to increase the production and export of dairy products (Jovanović 2020). In BiH, most farms do not follow modern milk production technologies, which results in lower yields and poorer milk quality compared to EU countries (Krilić, 2022). In addition, the informal sector in BiH has a large share in total production, which further complicates the monitoring of food quality and safety (FAS, 2020). Market fragmentation and competition with imported products also represent a significant challenge for domestic producers (FAS, 2020). This is confirmed by research on the milk market in the region of Southeast Europe, which shows that informal markets still play a dominant role in the distribution of dairy products (Kovačević et al., 2018).

According to USDA data from 2020, the average milk production per cow in BiH is 2,612 liters, which is significantly below the EU average, while more than 70% of farms in BiH are engaged in production with less than 5 cows (USDA, 2020). These data show the low productivity of dairy farms, the small number of cows on them, which on the other hand prevents the use of modern technologies (Krstić, 2018). Due to all of the above, many milk producers sell their products on local markets, while they are unable to increase the production and export of dairy products (Jovanović, 2021). In BiH, most farms do not follow modern milk production technologies, which results in lower yields and poorer milk quality compared to EU countries (Krilić, 2022). In addition, the informal sector in BiH has a large share in the total production, which further complicates the monitoring of food quality and safety (FAS, 2020). Market fragmentation and competition with imported products also represent a significant challenge for domestic producers (FAS, 2020). This is confirmed by research on the milk market in the region of Southeast Europe, which shows that informal markets still play a dominant role in the distribution of dairy products (Kovačević et al., 2018): There are several dairies in BiH, but many of them work below their capacity, with only a third of the maximum capacity of 2 million liters per day (SEE Industry, 2021). There are 23 largest dairies operating on the territory of Bosnia and Herzegovina with a processing capacity of 350 million liters, although their utilization is only about 60%. Milk and milk products are placed on the European market by 11 dairies (Ministry of Foreign Affairs and Economic Relations, 2024). According to the available data, in 2020 there were 35 entities registered in Bosnia and Herzegovina that deal with the processing of raw milk and with a processing capacity of 450 million liters (Komora BiH. 2024). Many dairies in BiH face problems such as low efficiency in production and products that do not meet high market standards. Most of the products that are placed on the market are of low added value, such as UHT milk, while products with a higher added value, such as aged cheese, are mostly imported (EBRD, 2018). Only a small number of farms and dairies have certificates that allow access to international markets, while many dairies remain oriented to local market niches.

In his research, Petrović (2021) states that the fragmentation of the milk market in Bosnia and Herzegovina and weaknesses in product distribution make it difficult to position domestic products on the wider market, while informal markets, which make up a significant part of the total production, additionally negatively affect product quality and safety]. Miljković et al. (2022) suggest that the development of institutional mechanisms could enable better connection and coordination of actors within the value chain, which would lead to cost reduction and improvement.

The lack of strategic coordination among milk producers and processors makes it difficult to improve the efficiency of the value chain. According to the analysis of Savić (2020), the

sector faces problems in organization and the lack of associations and clusters that could improve cooperation between actors. Additionally, the problem of market fragmentation leads to a mismatch between supply and demand, which negatively affects the prices of milk and other dairy products (Petrović, 2021). In recent years, the dairy sector in Bosnia and Herzegovina has also faced specific challenges related to the labor market, where high unemployment, but also the migration of young people to cities, make the availability of labor on farms a problem (Gajić, 2021)]. In addition, dairies struggle with financial problems, because many cannot invest in the modernization of production, which limits their competitiveness compared to dairies from EU countries and the surrounding area. (Matić and Kolega, 2021). According to Vuković (2019), the introduction of a new business model, based on clusters and the integration of all stages of the value chain, could improve cooperation between dairies and processors, and enable better market organization]. This approach can contribute to better coordination and strengthening the competitiveness of the dairy sector in BiH (Stojanović, 2021).

Despite all the challenges, dairy farming in Bosnia and Herzegovina has potential for growth, and proper management of the value chain could significantly contribute to strengthening the sector's competitiveness and improving economic performance. With the modernization and improvement of existing capacities, there is an opportunity to increase production, better product quality and strengthen the market position (Padjeni, 2018).

This paper analyzes the current structure of the value chain in the dairy industry in Bosnia and Herzegovina, identifies key actors and stages of production, and explores possible ways to improve the sector. Also, the challenges faced by domestic producers and processors are analyzed, as well as possible policies and strategies that can improve the competitiveness of the sector.

MATERIAL AND METHOD

The research is based on the analysis of secondary data from available sources, including reports of international organizations, academic papers and official statistics. Data collection was done based on several available sources and data. The problem here is the complexity of the country's organization, so the sources of data are different, and therefore sometimes contradictory, which should all be considered. Bosnia and Herzegovina was supposed to have a list of agricultural holdings in 2023, which was not implemented, which would certainly give a much clearer picture of the state of agricultural production.

Available data from the Ministry of Foreign Trade and Economic Relations, the Agency for Statistics of Bosnia and Herzegovina, the Federal Institute for Statistics of the FBiH, the Republic of Slovenia for Statistics of the RS were used for the analysis and preparation of the report. We took into consideration media data and official announcements of the Ministry of Agriculture, the Association of Agricultural Producers and media statements of students in the production chain. After analyzing this data, we started collecting data from producers, primarily at workshops organized by the Network for Rural Development of BiH. Here we adhere to the recommendations from the Guide for consultation and dialogue of members of civil society in order to strengthen the position of farmers in the value chain, which was made as part of the Farm to Fork Academy project.

A total of five consultative meetings were held with 85 participants. In parallel, meetings were held with producers, representatives, producers, representatives of cooperatives working in the dairy sector, buyers (large and small dairies). Representatives of the business community working in the dairy sector in BiH were also interviewed, as well as distributors of raw materials used in this sector and who are part of the value chain.

Interviews were also held with representatives of advisory services and the academic community. During the dialogue, and according to the recommendations from the guide, the key questions for discussion were the following:

1. What are the main challenges farmers face in their value chains?
 2. How can farmers position themselves in the value chain(s) to add value to their products?
 3. What are the key factors that determine the income of farmers in the value chain(s)?
 4. Is it realistic for farmers to influence decision-making in the value chain regarding product value?
 5. Is it possible for farmers to negotiate better price and production conditions with other stakeholders in the value chain(s)?
 6. Access to inputs such as seeds, animals, fertilizers, animal feed and agrochemicals at affordable prices.
 7. Access to seasonal workers with affordable wages.
 8. Storage and transport facilities for the preservation and transport of their products.
 9. Training and education on best practices for sustainable agriculture methods.
 10. Technology and tools to improve quality, efficiency and productivity.
 11. Market constraints and barriers (short vs. long supply chain issues).
 12. Financial support or credit to invest in their farming activities.
 13. Access to markets and market price information. - Export duties, legal issues or quality level issues (pesticide residue tolerance).
 14. Access to insurance and risk management services to protect against uncertainty. - Fair and transparent prices and contracts with buyers. - Access to advisory services and technical support
- Cooperation among farmers strengthens their market position by enabling collective action, which helps them better compete with larger, more consolidated players downstream in the supply chain (eg processors, retailers). This also helps in a fairer distribution of added value.
- Membership in producer organizations (PO) or cooperatives:
 - Awareness of the benefits of producer organizations (PO) or cooperatives and willingness to cooperate:
 - Obstacles to joining or establishing cooperatives
 - Awareness of sectoral programs
 - Are you currently a member of a producer organization (PO) or cooperative?
 - How would you rate your awareness of the benefits of joining a PO or cooperative? (Scale: Very aware, moderately aware, somewhat aware, not at all aware);
 - How willing are you to cooperate with other farmers to establish producer organizations or cooperatives to improve your bargaining power in the market? (Scale: very ready, moderately ready, a little ready, not ready at all)
 - What factors (trust, cultural barriers, financial constraints, lack of knowledge, etc.) prevent you from joining or starting a cooperative?
 - Are you aware of any sectoral programs that support farmer cooperation in your region?

Improving synergies and tackling unfair trading practices

The Directive prevents larger companies from exploiting their dominant position in the value chain. By protecting smaller suppliers such as farmers, the CAP ensures a fairer distribution of value within the supply chain. In addition, transparency through market observatories helps farmers make informed decisions based on accurate market data.

- Experience with unfair practices in the farmer-buyer relationship
- The role of agricultural associations and producers
- Fair trade organisations
- Transparency in prices and contracts
- Use and impact of market information systems

After interviews and consultations, data processing was done.

RESULTS AND DISCUSSION

The value chain of milk production in Bosnia and Herzegovina from field to fork includes seven (7) stages:

1. production of fresh raw milk,
2. purchase and transport of fresh raw milk,
3. milk processing and packaging,
4. distribution/wholesale
5. retail
6. consumer
7. additional service providers (advisory service, service providers, suppliers, etc.)

The production of raw fresh milk in Bosnia and Herzegovina represents one of the most important livestock production branches, and the dairy industry, that is, milk processing, is one of the leaders in the food industry. The first and most significant phase in which the biggest problems in the production of fresh raw milk were identified is the production of coarse feed for cows. Farmers produce coarse fodder on their own or leased plots and generally provide sufficient quantities of coarse fodder, but the quality of coarse fodder is not appropriate for the production potential of cows. The milk value chain begins with the cultivation of crops such as corn, alfalfa, clover, grasses, cereals, etc., which are used as bulk feed in the diet of dairy cows. Farmers produce all the bulk food they need on their farms, they only purchase ready-made concentration mixtures from industry. The production of fresh raw milk is carried out on farms that are mostly closed and have up to 5 dairy cows in the herd. Farms for milk production (accommodation, feeding, husbandry) are all over Bosnia and Herzegovina. The production of raw milk in the last couple of years has been more or less stable at slightly more than 600 million liters, although in certain years there are minor variations or deviations in terms of quantity. The production of raw cow's milk is dominant, with an average share of 97% in the total production of raw milk. In second place with an average share of 2% is sheep's milk and with 1% share is goat's milk. Unfortunately, milk production in Bosnia and Herzegovina is still underdeveloped, unorganized and often does not meet the needs of processing industrial dairy capacities. In addition to this, during the summer, with increased investments, individual milk producers invest additional funds in the development of their farms and their modernization. It is positive that today most of the produced cow's milk meets the quality criteria, especially the correction criteria in accordance with the requirements of international standards and quality regulations.

Purchase and transport of fresh raw milk, milk is purchased directly from farmers or milk purchase organizers (agricultural cooperative or d.o.o.) who appear somewhere as intermediaries in the purchase and further distribute to the dairy industry. On the other hand, we also have processors who directly contract the purchase of agricultural products. Milk is still transported and collected in the traditional way, in buckets (in smaller quantities), collective milk freezers (which ensure better milk hygiene and safety for consumers) or larger milk freezers located at individual larger milk producers. The transport is carried out by smaller or larger vehicles specially designed for milk transport, which takes it to the dairies. The packaging is typical for every processor. It is usually a tetrapak or plastic packaging. The packaging is designed so that the dairy products in the packaging are clean, fresh and safe for health.

The distribution of packaged dairy products from processors to markets, shops, etc. is carried out in specialized vehicles for transporting packaged dairy products (refrigerators).

Almost all retail establishments offer dairy products. Dairy products are always stored appropriately to maintain the freshness, cleanliness and healthiness of dairy products.

Consumers, milk and dairy products provide nine essential nutrients for children and adults and ensure health at all stages of life.

Additional service providers: Here we have a whole range of entities that offer support services such as transport, storage, marketing, quality control and certification within and across the value chain. Then there is the advisory service, which is recognized as key to providing to farmers (development varies in different parts of Bosnia and Herzegovina). Also included here are input suppliers, which include individuals or companies that provide farmers with basic agricultural inputs such as seeds, fertilizers, pesticides and machinery. Input suppliers play a key role in ensuring that farmers receive quality input, which can increase productivity and ultimately increase the value of the final product. In many cases, value chains are intertwined within input and output production (for example, seeds are provided by consolidators, fuel by retailers, etc.). To move on to further consideration, let us first present the numerical status of dairy cows in BiH.

Year	Federation BiH	Republika of Srpska
2002	142.000	143.000
2003	153.000	131.000
2004	157.000	137.000
2005	157.000	141.000
2006	158.000	150.000
2007	150.000	145.000
2008	155.000	157.000
2009	154.000	146.000
2010	145.555	124.000
2011	140.555	120.000
2012	137.910	110.000
2013	135.785	109.000
2014	135.233	108.000
2015	135.710	108.000
2016	132.626	106.000
2017	129.000	101.000
2018	125.405	96.000
2019	113.360	89.500
2020	110.615	81.720
2021	115.512	89,450

Tabel 1. Number of dairy cows

(Source: Federal Statistical Office (2022), Republican Statistical Office of Republika Srpska (2022))

In the period from 2002 to 2008, according to the data of the Statistical Office, there was a continuous increase in the number of milking cows. So that the largest number of milking cows in BiH was registered in 2008 (312,000). Since 2008, the number of dairy cows has been in constant decline, so according to the data, the total number of dairy cows in 2020 in BiH is 192,335.

Considering that according to the available data of the Institute of Statistics of the Republic of BiH from 1990, the number of dairy cows was 623,000. It must be pointed out that in that period there were fewer processing capacities for milk and that the quantity of purchased raw milk was significantly smaller.

The cultivation of milking cows, the production of raw milk and dairy products represents a great social support and income security for the inhabitants of rural areas throughout the country. About 9,000 agricultural producers in Bosnia and Herzegovina produce milk for the market, which results in all or part of the household's subsistence income from this production.

The dairy industry, which has about 23 dairies (data on the number of processing capacities varies up to 20-35), of which 11 export products to the European market, generates an annual income of more than 500 million KM and employs about 2,000 people. The total capacity of milk processing is about 350 million liters, and the utilization of dairy capacities is on average about 60%.

It is estimated that during the year 2023, around 616 million liters of raw cow's milk were produced, and the production recorded a slight increase of 2%. Although the number of dairy cows decreased by 29,000 heads or 14% in the period from 2019 to 2023, the increase in productivity, i.e. the improvement of the milk yield of 3,455 liters per head, affected the stability of the production of 600 million liters per year.

Produced raw milk is aimed at purchase, and on average 40-45%, while significant quantities of milk (up to 60%) end up being processed on the farms themselves, i.e. production of cheese, cream, sour milk, etc. and are used for own consumption and also for sale on the market.

The amount of raw cow's milk that producers delivered to dairies in 2023 amounted to 260,214 tons and is slightly higher by 3% compared to the previous year. The purchase price of raw cow's milk in 2023 was 0.90 KM/liter, and was higher by 0.20 KM per liter or by 29% compared to the average annual purchase price of milk from the previous year, which was 0.70 KM.

The total amount of milk and milk products produced by dairies in BiH in 2023 amounted to 219,260 tons, and a 5% decrease in total production was recorded compared to the production from the previous year. The structure of the dairy's production program has been the same for years, and drinking milk (full-fat, skimmed, partially skimmed milk) is still the leading product with a share of more than 60% in total production. The production of high-value products such as cow's cheese, butter and fermented products increased during 2023, while the production of drinking milk decreased.

The activity of processing milk and dairy products in the total export of agricultural and food products in 2023 has a share of 13%, in imports an average of about 6%, and a deficit of about 3%.

The import of milk and dairy products to the BiH market in 2023 amounted to 229 million KM and is slightly higher than the previous year by 2%. While the import stagnated, the exports of milk and milk products recorded a growth of 15%. The foreign trade balance of milk and milk products is negative, with the fact that in 2023 it is 10% lower. The rate of coverage of import by export of milk and milk products in 2023 was 56% and is higher by 5%.

In the import of milk and dairy products, the structure is as follows: the import of cheese dominates with a share of 50%, followed by cream with 14%, milk with a share of 8%, butter 7%, yogurt 6% and other fermented products 6%, whey 5%, milk spreads 3%, and milk powder 2%. In the export of milk and dairy products, the export of drinking milk dominates with a share of 55%, followed by the export of fermented products (buttermilk, sour milk, etc.) with a share of 14%, then cheese with 12%, yogurt 10%, cream 5%, milk spreads with 4%, butter 1%, and milk powder and whey less than 1%. Consumable milk and other fermented products (buttermilk, sour milk, etc.) are some of the products that have a surplus in foreign trade, while other products have an evident deficit.

The most important trade partners of Bosnia and Herzegovina in foreign trade of milk and

milk products are the countries of the European Union and CEFTA. On average, about 79% of milk and milk products from Bosnia and Herzegovina are marketed in CEFTA and about 20% on the European Union market. Regarding the import of milk and milk products, the European Union is in first place, from which on average about 87% of these products are imported into Bosnia and Herzegovina and about 13% from CEFTA. A significantly smaller percentage of milk and milk products is imported and exported to third markets.

The emergence of the COVID 19 pandemic in 2019, followed by the Ukrainian crisis, caused disruptions in the energy market, the growth of inflation and a significant increase in the prices of the basic inputs of agricultural production (60%) and animal feed, which directly affected the production and processing of milk in Bosnia and Herzegovina. Considering the significant increase in the price of basic inputs in milk production, the purchase price of milk increased, which inevitably led to an increase in the selling price of high-value products such as cheese and butter, yogurt, then milk, spreads and other dairy products sold in supermarkets.

The import of milk and dairy products to the BiH market in 2023 amounted to 229 million KM and is slightly higher than the previous year by 2%. While the import stagnated, the export of milk and milk products recorded a growth of 15%. The export of milk and milk products recorded growth after 2021 and increased from the export value of 93 million to almost 130 million KM during 2023, which is an increase of 39%. At the same time, the import of milk and milk products increased from the value of 159 million KM in 2020 to 229 million KM in 2023, which is an increase of 44%.

	2019	2020	2021	2022	2023
Import (milions KM)	180	159	174	224	229
Export (milions KM)	106	93	93	113	130
Deficit (milions KM)	-74	-66	-81	-111	-100
Import-export coverage (%)	59	59	54	50	56

Table 2. Foreign trade exchange of milk and milk products (2019-2023)

The foreign trade balance of milk and milk products was negative during the observed period, with the fact that in 2023 it amounted to about 100 million KM and is 10% lower, given that the growth of exports was recorded while imports remained at almost the same value level as the previous year. Milk is the most important product of the dairy industry in BiH and an export product that achieves a surplus in foreign trade. The share of milk in the total export of milk and milk products from Bosnia and Herzegovina to the global market is about 55%, while on the import side, this share is much smaller, amounting to only 8%.

	2019	2020	2021	2022	2023
Import (millions KM)	31	21	11	18	19
Export (millions KM)	61	66	60	65	71
Surplus (millions) KM)	29	46	49	47	52

Table 2. Foreign trade exchange of milk 2019-2023. year

Cream (cream) is a group of dairy products that, with a share of 14% in the total import of milk and dairy products, ranks second. As for exports, with a share of 5% in the total, the export of dairy products is ranked fifth

	2019	2020	2021	2022	2023
Import (milions KM)	21	17	22	37	32
Export (milions KM)	2	3	4	6	6
Deficit (milions KM)	-19	-14	-19	-30	-25

Table 4. Foreign trade exchange of sour cream (2019-2023)

Looking at the structure of cheeses imported to BiH, the market is dominated by the import of edamer with a share of 32% in the total import of cheese, followed by gouda with a share of 20%, other fresh cheese with a share of 11% and tilsit around 8%

CONCLUSIONS

The raw milk production development program in Bosnia and Herzegovina should be based on four categories of producers:

1. Small dairy herds with an average of up to 5 heads in the herd have no prerequisites or motivation for business advancement
2. Modern conventional production systems on adapted smaller farms with an average of 15 to 20 dairy cows in the herd. It is estimated that an average production of 4,500 to 5,500 liters of milk per cow per year could be achieved on these farms.
3. A system of specialized family dairy farms with 40 to 50 cows in the herd. On these farms, the production of 5,500 to 6,500 liters of milk per cow per year could be achieved.
4. A system of large milking cow farms (with more than 100 cows in the herd), which could ensure milk production of more than 6,000 liters per cow per year.

Milk production should be primarily focused on cheaper and better-quality products. This is possible with new technologies, especially in the way of keeping and treating animals, nutrition, hygiene, etc. Preference should be given to systems that maximize the use of cheaper inputs - fodder from lawns and arable crop rotation. The intensity of milk production per head should be contrasted with intensity, or profit per unit of area, or invested capital. The mainstay of the development of milk production should be voluminous forage.

Milk production on smaller farms should gradually take on the characteristics of organic, autochthonous.

Some of the conclusions are:

1. until the last moment before entering the EU, there is no need to throw out the incentive per liter of milk
2. before joining the EU, create a program to encourage the competitiveness of small producers, so that they grow to 50 - 100 dairy cows, and survive after joining the EU.
3. deductions for capital investments must be at least 65% for all farmers and 80% for young farmers. Support of 40 or 50%, and up to 50% is not enough. The restructuring of milk production and the creation of a larger number of market-oriented farms must begin as soon as possible.
4. Solve the issue of land management. In the EU, everything is going smoothly and all those who do not have this issue resolved will be extinguished. Milk production cannot do without hectares.
5. Adopt a rulebook that will regulate the issue of using blue diesel in BiH in accordance with

EU standards (in Croatia they have 180 l per cow and 120 per ha, which costs 40-50% of the regular price of diesel.

6. Resolve the cattle marking system - marking in BiH is not efficient and is not aligned with EU rules. The grower should mark himself.

7. It is necessary to create a strategy for the transition of the dairy sector to the EU

8. Cooperation between the private sector and state institutions must be improved

Of the seven largest milk processors in B&H, three dairies are owned by foreign investors, who participate in the purchase and processing of raw milk with 64%. The production program of these dairies is conditioned by the owner's requirements.

Cheese production participates in the production program only with some 3 to 4%, and butter production 0.20%. Cheese production is mainly in smaller processing facilities. In the future, more importance should be given to longer-lasting dairy products and value-added products. So traditional production should be preserved, and measures should be taken to standardize and protect the geographical origin and originality of some types of cheese.

In the markets, cheese and cream are mainly sold as domestic traditional products

ABSTRACT

Mentha pulegium L., a member of the Lamiaceae family, is valued for its therapeutic properties by people around the world. In Algeria, commonly called “fliou”, it has long been recognized for its ability to treat a wide range of diseases. Antimicrobial properties of plant essential oils (EO) have been investigated through several observations and clinical studies which purpose them as potential tools to overcome the microbial drug resistance (MDR) problem. The aim of this research was to study the antibacterial effect of a traditional plant EO, *Mentha pulegium* L., against clinical isolates of methicillin resistant *Staphylococcus aureus* (MRSA) through disk diffusion method. The EO showed very effective bactericidal activity towards the majority of the tested bacterial strains with inhibition zone diameters in the range of 17.06 - 24.50 mm.

The obtained results are therefore promising and thus pave the way for manufacturers to use the essential oils of *Mentha pulegium* L. in the pharmaceutical and food industries.

Keywords: *Mentha pulegium* L., Essential oil, Antibacterial activity, *Staphylococcus aureus* MRSA.

INTRODUCTION

Staphylococcus aureus is one of the major pathogens credited as being responsible for nosocomial and community acquired infections in humans (Fridkin et al., 2005, Weiner et al., 2016). Colonizing the normal commensal flora of humans and many animals, this opportunistic bacterium is considered the main cause of hospital-acquired infections, generating a variety of symptoms, from mild localized infection to potentially fatal sepsis (Egert et al. 2015).

The emergence and spread of multidrug-resistant (MDR) bacterial pathogens have substantially threatened the current antibacterial therapy (Boucher et al., 2009).

MDR bacterial infections often lead to increased mortality, longer stays in hospitals, and higher cost of treatment and care (Boucher et al., 2009; Giamarellou, 2010).

The resistance to antibiotics by microorganisms has increased because, generally, bacteria have the genetic ability to transmit and acquire resistance to them. Bacteria that belong to the *Staphylococcus* genus constitute one of the most serious epidemiological problems. *S. aureus* has the strongest virulence potential among all the staphylococcal species (Ounaissia et al., 2019).

The therapeutic options for these pathogens are extremely limited and physicians are forced to use expensive or previously discarded drugs that are associated with significant side effect to the patients health (Boucher et al., 2009).

The issue of alternative therapies for diseases of staphylococcal etiology has been recently widely discussed by Kurlenda and Grinholc (Kurlenda et al., 2012). The compounds isolated from plant origin, especially essential oils, seem to be the most promising considering their application for both prevention and treatment of staphylococcal infections (Szweda et al., 2016).

The use of essential oils has been shown to possess potential in the treatment of infections, and is safe in terms of human and animal health. Essential oils generally regarded as safe show antimicrobial proprieties and antibacterial resistance that has not been reported after prolonged exposure (Pozzo et al., 2012).

Mentha pulegium L. is one of the *Mentha* species commonly known as pennyroyal. The flowering aerial parts of *Mentha pulegium* L. has been traditionally used for its antiseptic for treatment of cold, sinusitis, cholera, food poisoning, bronchitis and tuberculosis, and also as antifatulent, carminative, expectorant, diuretic, antitussive, menstruate. The ingredients of *Mentha pulegium* L. oil have been subjected to a number of studies which have shown a difference in its constituents depending on the region of cultivation and there have been some variations in the constituents from different countries. It has been found *Mentha pulegium* L. oil from Bulgaria contains pulegone (42.9–45.4%); from Uruguay; pulegone (73.4%), isomenthone (12.9%); from Egypt; pulegone (43.5%), piperitone (12.2%); from Tunisia, pulegone (41.8%), isomenthone (11.3%). These studies showed three chemotypes of *Mentha pulegium* L. with the following major oil components (1) pulegone, (2) piperitenone and/or piperitone and (3) isomenthone/neoisomenthol (Mahboubi et al., 2008).

The aim of this research was to study the antibacterial effect of a traditional plant EO, *Mentha pulegium* L., against clinical isolates of methicillin resistant *Staphylococcus aureus* (MRSA) through disk diffusion method.

MATERIAL AND METHOD

Plant material

The species *Mentha pulegium* L. was harvested in the region of El Taref (northe astern Algeria) in April 2023. The identification of the plant was done with the key to determining the flora of Quezel and Santa (Quezel et al., 1963). Specimens were kept at the Laboratory Medical Botany, Department of Pharmacy, Faculty of Medicine Annaba-Algeria.

Essential oil

Essential oil of flowering tops of *Mentha pulegium* L. has been procured from production unit of essential and vegetable oils “Elexir Est” Algeria.

Antibacterial test

The test of the sensitivity of the bacteria is carried out by the diffusion method in agar medium (the disk method). It is a method similar to that of the antibiogram which consists in determining the sensitivity of a bacterial strain vis-à-vis one or more substances (Falleh et al., 2008). The antibacterial activity of the essential oil of the aerial parts (stem and leaf) of *Mentha pulegium* L. is evaluated vis-à-vis four bacterial strains ; *S.aureus* ATCC23, *S.aureus* ATCC00, *S.aureus* ATCC13 and *S.aureus* MRSA. These strains were kindly provided by the Microbiology Laboratory Manager at Annaba Faculty of Medicine, Algeria.

Preparation of The Inoculum

By taking twenty tubes that each contains 5 ml of sterile physiological saline. Using a platinum loop, some well isolated colonies are scraped from each of the bacteria, each of which will be discharged into a tube. For the preparation of the different concentrations of extracts, 2, 5 mg of each freeze-dried extract (methanolic extract of leaf and stem), are introduced into a labeled tube, in which we added 1 ml of dimethylsulfoxide (DMSO), solvent without any antibacterial effect. The tubes are vortexed until complete dissolution of the extract, and the dilutions are prepared to obtain 1/2, 1/4, 1/8 and 1/16 concentrations from the stock solution.

Seeding should be done within 15 minutes after the preparation of the inoculum. In 16 sterile Petri® dishes, 20 ml of agar are poured. After solidification of the medium, the latter is inoculated with 1 ml of bacteria to be studied. Then, it is spread on the surface using a glass rake. Sterile 5 mm diameter disks prepared in Whatman® n°1 papers are impregnated with a sterile metal forceps in each concentration and placed on the surface of the solidified medium (Mueller-Hinton) at the rate of 6 disks per box (3 discs of leaf, 3 disks of stem). The dishes were incubated for half an hour at room temperature, then for 24 to 48 hours in an oven at 37 ° C. The reading is carried out by measuring the diameter of the inhibition zone (Ø), which translates into a translucent halo around each disc; the presence or absence of a halo would explain the sensitivity or the resistance of the germs vis-a-vis extracts tested; according to a symbolic notation scale from - to +++ (Meena 1994; Jeovetz 2000; Ounaissia et al., 2022).

Table 1. Sensitivity of microbial strains according to zones of inhibition

Sensitivity	Inhibition zone
Not sensitive or resistant(-)	Diameter <10 mm
Sensitive (+)	Diameter between 10 to 16 mm
Very sensitive (++)	Diameter between 16 to 25 mm
Extremely sensitive (+++)	Diameter > 25 mm

RESULTS AND DISCUSSION

Reading Antibigrams

The results of the antibacterial activity are shown in Table 2.

Table 2. Inhibition Diameter (mm) of raw essential oil of *Mentha pulegium* L., and these dilutions

Stains	Raw (EO)	Dilution			
		1/2	1/4	1/8	1/16
<i>S.aureus</i> ATCC23	17.06 ++	11.30 +	11.96 +	11.09 +	12.70 +
<i>S.aureus</i> ATCC00	24.50 +++	13.25 +	12.57 +	9.85 +	8.06 +
<i>S.aureus</i> ATCC13	19.10 ++	20.56 +++	9.71 +	7.99 R	9.48 +
<i>S.aureus</i> MRSA	17.86 ++	14.76 ++	13.17 +	10.13 +	8.58 +

The four strains of *Staphylococcus* tested, were very sensitive to the essential oil of *Mentha pulegium* L. with diameters of inhibition zones ranging from 17.06 mm to 24.50 mm, the most sensitive strain was *S.aureus* ATCC00 with a diameter of inhibition zone of 24.50 mm for the essential oil in the crude state (Table 2).

According to a study by Barchan et al (2025), on the essential oil obtained from the aerial parts of *Mentha pulegium* L. collected in northern Morocco, it was reported that the oil was significantly more effective against Gram-positive bacteria and *S. aureus* was the most sensitive of all the strains tested.

In the literature, it is recognized that essential oils of several *Mentha* species including *M. pulegium* possess antimicrobial properties (Daferera et al. 2003). The essential oil of *Mentha pulegium* is rich in pulegone (30-70%) (Aghel et al. 2004). Pulegone is recognized for its various antibacterial effects. It has shown significant antibacterial effect against *S. aureus* (Duru et al. 2004).

Gram positive bacteria are known to be more susceptible to essential oils than Gram negative bacteria (Russell et al., 1991). Gram negative organisms are less susceptible because they possess an outer membrane surrounding the cell wall which restricts diffusion of hydrophobic compounds through its lipopolysaccharide covering. Gram positive bacteria with a simple membrane structure are less protected against the diffusion of fine essential oils particles Hogan et al., 2002).

There is evidence in the literature that the essential oils of some Lamiaceae plants possess a moderate to good antibacterial activities (Sokovic et al., 2006).

In an other report (Mahboubi et al., 2008) piperitone and piperitenone were found the main components of *M. pulegium* essential oil (71.1%) and exhibits a remarkable antibacterial activity against Gram positive bacteria than Gram negative ones.

Overall, we can conclude that *Mentha pulegium* EO is one of the most promising natural compounds that can be used to develop safer antibacterial agents and that its effective combination with antibacterials may be used in the future to treat diseases caused by *Staphylococcus aureus*.

CONCLUSIONS

Plant extracts have great potential as antimicrobial compounds against microorganisms. Thus, they can be used in the treatment of infectious diseases caused by resistant microbes. The results of this study suggest that *Mentha pulegium* L. essential oil possesses antibacterial properties. This EO could be used as bacterial growth inhibitory agent in new drugs in therapy of *Staphylococcus* diseases. Although this study has investigated in vitro antibacterial activity, extensive in vivo studies could confirm the potential usefulness of this plant's essential oil in combating antimicrobial resistance. However, further research is required to better understand the scientific and biotechnological basis values of applied phytotherapy.

THE HOME GARDENS AS BIOCULTURAL RESERVE OF LOCAL PLANT DIVERSITY AND TRADITIONAL KNOWLEDGE

Nikolaya Velcheva, Valko Neshev

Agricultural Academy, Institute of Plant Genetic Resources – Sadovo, BULGARIA

Corresponding author e-mail: nikolaya_velcheva@abv.bg

ABSTRACT

The garden is a biocultural reserve where valuable local plant genetic resources, as well as knowledge about their cultivation and use, are conserved and passed down from generation to generation. Especially in the case of food plants, an important example of which are beans, the desire to preserve landraces is result from the emotional devotion towards the traditional taste of local dishes. In this context the role of home gardens as repositories of biological diversity has been acknowledged and a comprehensive, interdisciplinary investigation of their agro-biodiversity is needed. Home gardens, whether found in rural or urban areas, are characterized by a structural complexity and multifunctionality which enables the provision of different benefits to ecosystems and people. Local farmers engage in food production for subsistence or small-scale marketing and the variety of crops and wild plants provides nutritional and medicinal benefits. At the same time, home gardens are important social and cultural spaces where knowledge related to agricultural practices is transmitted and through which households may improve their income and livelihoods. The present study summarizes available documentation on 11,385 local accessions, collected from expeditions in Bulgaria. It discusses future opportunities and prospect of promoting their role in conservation of agricultural biodiversity and cultural heritage. The results support the hypothesis that home gardens sustain rich diversity while contributing to its conservation. However, with the intensive agricultural production, home gardens are unlikely to be preserved if they are not actively mainstreamed in production and conservation policies through add value as cultural heritage. The research work was carried out under the SVK-BGR cooperation project DIGIVALPGR.

Keywords: Landrace, *On farm* conservation, Agroecosystem, Heritage, Add value.

INTRODUCTION

The impact of home garden biodiversity on environment and socioeconomic status of rural populations is reported from report of FAO (2025). The sustainable production and consumption of local crops provide a key part of the nutritious food in the face of different challenges, such as climate change, aged farmers, change of dietary patterns (Pushpakumara et al., 2020; Ivanova et al. 2021; Korpelainen, 2023).

Plant diversity of traditional varieties in Balkan countries is characterized by a large number of crops – cereals, vegetables, legumes, spices, medicinal, and ornamental species. They played an important role for research due to a high genetic variability, making them a potential source of valuable genes coding for economically significant characteristics of importance for agricultural crops, such as disease resistance, drought resistance, quality traits (Conversa et al., 2020). Beside their utilization in breeding programs, they might also be used in small scale farming especially in mountainous districts, due to their adaptability to the specific environmental conditions where they have evolved (Kreiken and Asveld, 2025). Intensive agriculture is however becoming more and more predominant and use of modern cultivars and hybrids giving higher yields and thereby being more profitable are taking over the market. This is causing a continuous loss of old, traditional cultivars and landraces (Vakoufaris, 2024).

Inventorying of local landraces in Bulgaria and Slovakia was therefore initiated by a team of experts from both National seed genebanks. The project DIGIVALPGR started in 2024 and the research network was established providing a platform for facilitating project collaboration. During a preparatory survey for the proposal the partners reported about the presence of conserved local landraces from the rural areas of the respective countries, as well as the danger of their extinction (Mendel et al., 2019; Velcheva and Stoilova, 2021). Within the project working program, collecting missions were conducted.

The aim of the study is to evaluate the inventory of traditional varieties in Bulgaria as an innovative solution to climatic and social challenges.

MATERIAL AND METHOD

The researchers of the teams are members of the European Cooperative Program on Plant Genetic Resources (ECPGR) working groups of documentation and by crop groups. Therefore, prioritized species for collecting were mainly beans, vegetables, medicinal and aromatic plants. The determination of the sites was based on long-term experience of collecting missions in the project countries during which regions with very rich agro-biodiversity had been identified. For example, in Bulgaria such regions are the geographic zones the Rhodopes and Stara Planina Mountains. In these areas there are villages placed between 450-1250 m altitudes. Many of them are even now with isolated access. In these villages old varieties are still commonly found. Both Slovakian and Bulgarian partners pointed out that the main part of old landraces and cultivars are preserved in certain remote and marginal areas in the mountainous depressions where old farmers still cultivate them. In the Rhodopes Mountain in Bulgaria, very diverse populations of common bean were found in the past. This was confirmed after several expeditions during the last 20 years, organized by IPGR-Sadovo. A lower number of local varieties have been grown *on farm* in the urbanized parts of the country.

According to the ECPGR (2017) collecting missions were conducted during 2024 and 2025 by each partner in the own country and also joint expedition in Bulgaria was organized.

During the period activities were carried out according to the following plan:

- Organizing collecting missions in predicted rural areas in each of the partner countries:
 - planning the expeditions (detailed terrain plans - itinerary, documentation and information on geographical, soil, climatic and agro-socio economic data); preparing informative materials (leaflets) for the local population;
 - collecting expeditions in targeted areas (Figure 1).
- Compiling the passport data of the collected samples:
 - immediately after collecting, EURISCO Passport Descriptor was used to compile passport data of the collected samples (FAO/Bioversity, 2017).
- Multiplication, characterization, evaluation, conservation of the collected accessions:
 - the seeds of the collected accessions are preparing for conservation according to international standards (depending on the amount of available material).
- Documentation, analyzing and comparing obtained data:
 - obtained data were documented, computerized, collated and analyzed among partners in the project.
- Results and progress from the DIGIVALPGR project:
 - the project partners from Bulgarian and Slovakian genebanks compiled the results and achievements in progress.

Figure 1. Joint Bulgarian-Slovakian collection mission in the region of Yambol, June 2025

RESULTS AND DISCUSSION

During the period 1982-2025 the germplasm stock of the National seed genebank in Sadovo was enriched with 11,385 local accessions. Currently, landraces comprise 35 % of the genebank holdings. The accessions from collecting missions composed of local varieties and populations from home gardens and crop wild relatives, obtained in their natural habitats. With the highest number of local gene pool are grain legumes and vegetables, followed by cereals.

During 2024-2025 a qualitatively new cooperation between the Bulgarian and Slovakian genebanks by sharing experience and good practices in the field of conservation, characterization, evaluation and documentation of local plant genetic resources is established. A questionnaire for collecting passport and ecological-geographic characteristics has been developed and is being filled out. The Bulgarian partner inventoried in total 10 geographical localities. For all collecting sites, longitude, latitude and altitude were recorded with GPS and registered in passport data files.

With regards to altitude inventorying was carried out from 156 m in Sadovo, Plovdiv region and 157 m in General Inzovo, Yambol region up to mountain an altitude of 1,259 m in Sarnitza, Smolyan region.

The dominance of the common bean landraces (12 acc.) among the collected accessions is due to several factors. Firstly, common bean is very often cultivated on small plots in backyards and home gardens together with vegetables and spices. Secondly, it is too expensive for the small farmers to buy seeds from new varieties for own household cultivation and consumption. Instead, they maintain their own seeds which very often have been grown for generations. And one of the most important is that the local varieties are characterized with special traditional taste and are used for connected with the locality dishes (Calvet-Mir et al., 2016).

During the collecting of accessions of these crops, it was considered necessary to receive detailed information from growers. The researchers provided information about collecting source and recorded it in files together with passport data (Table 1). Most of these accessions were collected from home gardens (24 acc.) or sent by post (3 acc.) as a result from dissemination activities in Municipalities of Svoge and Mezdra (Figure 2 and 3).

Figure 2. Collected accessions from local farmers in the villages of Ochindol, Lakatnik, Levishte

Figure 2. Seeds from local varieties and description sent by post from farmers – donors of plant genetic resources

Local markets are still a valuable source of old, traditional varieties and landraces. Around 25% of the conserved landraces in IPGR-Sadovo are derived from green markets however being collected in smaller quantities and multiplied. Sometimes, interesting material, which was difficult to find during collecting expeditions in villages, could be collected at the green markets.

Possibilities and challenges for promoting landrace conservation through the use of successful examples:

- Produce and develop typical local products;
- Development of new (e.g. environmentally friendly) farming systems based on diverse varieties;
- Development of local food supply systems, including community and home gardens;
- Develop companies purposely dedicated produce and sell seed/propagation material of landraces.

During the project activities some advantages of old varieties vs modern cultivars landraces were recorded:

- Competitive yield under low input conditions;
- Special value for wildlife (nature protection);
- Agritourism advantage (local products);
- Biomass yield, tolerance, environmental advantage.

Figure 4. Demonstrative garden with local accessions with Bulgarian and Slovak origin

To promote the conservation of local plant genetic resources to students and other guests of the Institute, a demonstration garden with traditional local varieties has been created (Figure 4).

* Data source – Information System of Plant Genetic Resources, Sadovo, Bulgaria						

CONCLUSIONS

The region of Bulgaria is still rich in agricultural biodiversity, represented by local landraces. This fact was supported by the result of conducted collecting missions during 2024 and 2025, when 27 new accessions of local landraces were collected. There is however an impending danger of extinction caused by many factors, such as intensive agricultural practices and use of modern cultivars, migration of the population from villages to the cities, aging of the population in rural areas that traditionally cultivated local populations etc. Therefore, it is considered necessary to continue with collecting expeditions. In general, the result of this project has significant positive impact on the present and future work of the project partners and their institutions, not only in the field of plant genetic resources, but also in the field of plant breeding and entire crop production.

The collected accessions represent richness of biodiversity, that is now prevented from being lost and will soon be available for breeding and research in the region, as well as for the entire scientific community. The next and very important steps are to regenerate, characterize and evaluate the collected material.

It was found that the home gardens sustain rich diversity while contributing to its conservation. However, with the intensive agricultural production, home gardens are unlikely to be preserved if they are not actively mainstreamed in production and conservation policies through add value as cultural heritage.

Digitization and open access to conserved genebank collections increase and optimize the use of the gene pool in breeding programs for the adaptability of genetic materials to changing climatic factors and satisfy the needs of farmers to return the traditional varieties to practice.

The study is in line with the EU 2030 strategy for the conservation of biodiversity and addressed to the implementation of National Programs on Plant Genetic Resources for Food and Agriculture.

The results of the study find their application in the overall process of protecting biodiversity and nature, increasing the resilience of crops to dynamic environmental conditions in order to guarantee the production of healthy and high-quality food.

ACKNOWLEDGEMENTS

This research work was carried out under the SVK-BGR cooperation project DIGIVALPGR “Digitalization and valorization of local plant genetic resources in Bulgaria and Slovakia in the framework of maintaining compatibility and interoperability in the European area” with the support of Bulgarian National Science Fund, Contract number KP-06-Slovakia/9/13.08.2024.

ABSTRACT

In this study, the static behavior of functionally graded (FG) porous sandwich beams is investigated through theoretical modeling and numerical analysis. FG composite structures are advanced engineering materials characterized by a continuous and gradual variation of material properties along the thickness direction, enabling the simultaneous achievement of low weight, high mechanical strength, and stiffness. In sandwich beam design, applying different distributions of density and elasticity to the core and face layers allows for the optimization of the structure's overall mechanical performance.

To model the response of the porous sandwich beam under static loading, the Hyperbolic Shear Deformation Theory (HSDT) is employed, and the governing equations are derived using Hamilton's principle. The HSDT approach provides more accurate results for thick beams by effectively accounting for shear deformation effects.

The derived governing equations are solved analytically using the Navier solution technique. The study presents a comprehensive analysis of dimensionless displacement distributions under various material gradation functions, porosity levels, and simply supported boundary conditions. The results clearly demonstrate that both the porosity ratio and the distribution of material properties significantly influence the static response and stiffness characteristics of the beam.

Keywords: Functionally graded materials, Static analysis, Porous sandwich beam, Porosity ratio

LITERATURE REVIEW

Displacement analysis plays a critical role in determining the mechanical behavior of functionally graded porous sandwich beams, particularly in engineering applications where a balance between lightness and strength is required. In this context, the literature reveals how displacement behavior varies under different material distribution models, porosity ratios, and boundary conditions.

Solar and Taşkın (2024) investigated the bending and vibration behavior of functionally graded porous sandwich beams using classical beam theory and the Navier solution method. Their study demonstrated that displacement values are sensitive to the porosity ratio, material gradation profile (power-law exponent), and geometric parameters (L/h ratio). The analyses conducted with two different material types—one with symmetric and the other with homogeneous porosity distribution—showed significant displacement differences between the functionally graded face layers and the homogeneous core layer.

In the study conducted by Turan, Hacıoğlu, and Balcı (2024), the displacement behavior of functionally graded porous beams was analyzed in the ANSYS APDL environment,

considering the porosity coefficient and distribution type. The numerical results were compared with data from the literature, thereby demonstrating the modelability of changes in displacement responses due to porosity.

Shabani et al. (2023) conducted static buckling and free vibration analyses of two-dimensional functionally graded metal-ceramic porous beams. Using Hamilton's principle and the Galerkin method, they accounted for material variation along the thickness and length as well as porosity effects, examining how FG power indices, porosity, and slenderness ratios influence the beam's non-dimensional frequency and buckling response. The results demonstrated that the proposed higher-order beam model accurately captures the effects of transverse shear deformation compared to classical theories.

Taşkın and Demirhan (2020) focused on the free vibration analysis of porous FG beams. However, the fundamental equations of motion and the Navier-type solution method employed in their study are also applicable for evaluating displacement behavior. Their analysis, based on equations derived via Hamilton's principle, revealed that the porosity ratio is a determining factor in the displacement response.

Turan and Kahya (2021) examined the free vibration and buckling behavior of functionally graded sandwich beams. Although the study primarily addressed dynamic responses, the displacement functions obtained for the proposed Type A and Type B structures contribute to the understanding of displacement behavior in relation to boundary conditions and material gradation parameters. Solutions based on trigonometric series functions are particularly valuable for understanding the effects of beam geometry under bending.

Chopan and Noori (2023) investigated the elastic and viscoelastic forced vibration behavior of functionally graded porous sandwich beams using theoretical analysis and the finite element method. Three-layered beams were modeled considering different boundary conditions and porosity functions, and the effects of material gradation and damping ratio on the dynamic response were examined. The results showed that the porosity function and material gradation significantly influence the amplitude and period, while in the viscoelastic case, increased damping causes a faster reduction in amplitude.

El Khouddar et al. (2021) examined the thermal nonlinear free vibration of functionally graded (FG) beams using Euler-Bernoulli theory and Hamilton's principle, considering von Kármán geometric nonlinear strains. They assumed temperature-dependent material properties with a simple power-law distribution, and their results highlighted the impact of thermal conditions and volume fraction on the dynamic response of FG beams.

Phung-Van et al. (2024) investigated the nonlinear bending behavior of functionally graded (FG) beams under various boundary conditions using the Ritz method. In their study, displacements were modeled with higher-order polynomials (Pb- Ritz) satisfying geometric boundary conditions, and von Kármán type geometric nonlinear strains were considered. Their results highlighted the influence of material properties, geometric parameters, and boundary conditions on the displacement and stress fields of FG beams.

Bridjesh et al. (2023) investigated the buckling behavior of two-directional porous functionally graded beams using a higher-order shear deformation theory. The study computed the buckling loads and displacements of the beams under various boundary conditions and material gradations using polynomial-based formulations. The results highlighted that porosity distribution, material gradation, and boundary conditions have significant effects on the buckling response of the beams.

INTRODUCTION

Composite materials are engineering materials formed by combining two or more distinct materials at the macroscopic scale, offering a wide range of properties such as high strength, low weight, and good thermal performance. Laminated composites are obtained by stacking different material layers, and due to the differences between these layers, discontinuities may occur in temperature and stress distributions. Such discontinuities can adversely affect structural performance. To address this issue, functionally graded materials (FGMs) have been developed. In FGMs, material properties vary continuously along the thickness direction, thereby reducing stress concentrations at the interfaces (Taşkın & Demirhan, 2020). Despite providing superior mechanical and thermal properties, FGMs inevitably develop structural porosities during manufacturing. These pores can significantly influence the mechanical performance of the material. Porous functionally graded beams (FGPBs) are produced with a gradual distribution of metal and ceramic phases, and the presence of porosity is an important parameter that must be considered in both static and dynamic analyses (Turan, 2022).

Although FGMs offer enhanced performance, the formation of microscopic pores during the fabrication process is unavoidable. These pores directly affect elastic modulus, natural frequencies, and vibration behavior. Therefore, it is essential to include the porosity factor in the mechanical and dynamic analyses of porous FGM structures (Wattanasakulpong & Chaikittiratana, 2015; Ebrahimi & Mokhtari, 2015). Recent studies have shown that porosity significantly influences not only vibration behavior but also the performance of beams under static loads. Sadoun (2017) demonstrated that the porosity parameter substantially alters the elastic modulus and overall mechanical behavior, while Hamed, Sadoun, and Eltaher (2019) investigated the effect of different porosity models on the static response of nanobeams, highlighting the critical role of pore distribution on deformations. Similarly, Akbaş (2018) and Alnujaie et al. (2021) analyzed the dynamic behavior of thick functionally graded porous beams and indicated that proper material distribution can mitigate the negative effects of porosity. These studies collectively reveal that the impact of porosity cannot be ignored in either dynamic or static analyses. Moreover, the analysis of sandwich structures is of great importance in engineering applications. Using functionally graded layers on the faces and porous materials in the core provides advantages in terms of both strength and stiffness. Literature emphasizes that porosity distribution and the material grading index directly affect the mechanical behavior of sandwich beams, and neglecting these parameters can lead to significant deviations in results (Ebrahimi, Ghasemi, & Salar, 2015). In this context, the present study focuses on the static displacement analysis of functionally graded porous sandwich beams. The effects of different porosity models and material distribution parameters on the displacement behavior of sandwich beams are examined.

In this study, the static displacement behavior of functionally graded (FG) porous composite sandwich beams was investigated. The beam possesses an FG material structure, with mechanical properties and porosity gradually varying through the thickness; the core and face layers exhibit different density and stiffness values. In the first stage, the geometrically nonlinear equations of motion were derived using the hyperbolic shear deformation theory and Hamilton's principle. Subsequently, these equations were solved using numerical methods, and dimensionless displacement distributions were analyzed under various material grading functions, porosity ratios, and simply supported boundary conditions. The results clearly illustrate the influence of porosity and material distribution on beam behavior, providing valuable engineering insights for the design of FG structures.

MATERIAL AND METHOD

1.1. Definition of Effective Properties in Functionally Graded Material Beams

Various homogenization or blending methods have been developed to describe the characteristics of multi-phase materials. Among these methods, the Voigt-type mixing rule is particularly preferred for estimating the effective properties of functionally graded materials. (Taşkın & Demirhan, 2020)

$$P(z) = P_1 + (P_2 - P_1)V_s(z) \quad (1)$$

Here, $P(z)$ represents the material property, while $V_s(z)$ denotes the volume fraction function. In this study, the most commonly used exponential function is selected for $V_s(z)$. (Wakashima et al., 1990).

$$V_s^{(1)}(z) = \left(\frac{z-h_0}{h_1-h_0} \right)^p, \quad h_0 \leq z \leq h_1, (0 \leq p \leq \infty) \quad (\text{FG bottom surface}) \quad (2)$$

$$V_s^{(2)}(z) = 1, \quad h_1 < z < h_2, (0 \leq p \leq \infty) \quad (\text{Ceramic core}) \quad (3)$$

$$V_s^{(3)}(z) = \left(\frac{z-h_3}{h_2-h_3} \right)^p, \quad h_2 \leq z \leq h_3, (0 \leq p \leq \infty) \quad (\text{FG top surface}) \quad (4)$$

For $p = 0$, the material is homogeneous, while for $p > 0$, the properties vary functionally.

In this study, a functionally graded beam with length L and height h is employed, and its geometric configuration is depicted in Figure 1.

Figure 1. Porous functionally graded beam

A functionally graded material beam with length L and height h is characterized by a spatially varying elastic modulus $E(z)$ and density $\rho(z)$.

Various models have been proposed in the literature to represent porosity distribution. The first model (Type A) assumes that pores are uniformly distributed across the cross-section. However, several studies have observed that porosity is often non-uniform, typically concentrated near the mid-plane and decreasing toward the surfaces. This observation led to the development of a non-uniform porosity distribution model (Type B). In addition to these studies, further analyses have also been conducted to examine different types of porosity (Type C).

Figure 2. Type A and Type B porosity distribution models (Taşkın & Demirhan, 2020)

Effective material properties for Type A(Fig. 2); (Solar & Taşkın, 2024)

$$E(z) = E_m + (E_s - E_m)V_s(z) - \frac{e}{2}(E_s - E_m) \quad (5)$$

$$\rho(z) = \rho_m + (\rho_s - \rho_m)V_s(z) - \frac{e}{2}(\rho_s - \rho_m) \quad (6)$$

Effective material properties for Type B(Fig. 2); (Solar & Taşkın, 2024)

$$E(z) = E_m + (E_s - E_m)V_s(z) - \frac{e}{2}(E_s - E_m) \left[1 - \left(2 \frac{|z|}{h} \right) \right] \quad (7)$$

$$\rho(z) = \rho_m + (\rho_s - \rho_m)V_s(z) - \frac{e}{2}(\rho_s - \rho_m) \left[1 - \left(2 \frac{|z|}{h} \right) \right] \quad (8)$$

Effective material properties for Type C; (Kurpa et al., 2023)

$$E(z) = E_m + (E_s - E_m)V_s(z) - \frac{e}{2}(E_s + E_m) \left[1 + \left(\frac{z-h}{\frac{h}{2}+h} \right) \right] \quad (9)$$

$$\rho(z) = \rho_m + (\rho_s - \rho_m)V_s(z) - \frac{e}{2}(\rho_s + \rho_m) \left[1 + \left(\frac{z-h}{\frac{h}{2}+h} \right) \right] \quad (10)$$

A porosity ratio e represents a functionally graded material without any pores. As e increases, the porosity within the material increases, leading to a decrease in the elastic modulus. A volume fraction exponent $p=0$ corresponds to a fully ceramic material; as p increases, the metallic character of the material increases. When p is non-zero, the bottom surface exhibits metallic properties, while the top surface exhibits ceramic properties. (Taşkın & Demirhan, 2020)

1.2. Hyperbolic Shear Deformation Beam Theory

The hyperbolic shear deformation beam theory was introduced to investigate the mechanical behavior of planar sandwich-type structures. This theory aims to provide more reliable results by accurately considering the shear stresses that develop on the top and bottom surfaces of the beam. Within this framework, the normal and shear stresses at any point along the beam are expressed in relation to the first and second derivatives of the displacement functions. This correlation represents one of the key principles underlying the governing equations of motion for the beam.

(Soldatos et al., 1992) expressed the displacement field used in their study, which

employs the hyperbolic shear deformation beam theory.

$$u(x, z) = u_0(x) - \frac{zdw_0}{dx} + f\phi(x) \quad (11)$$

$$w(x) = w_0(x) \quad (12)$$

In Equation (11) and in equation (12) u_0, w_0 represent the displacements in the x and z directions, respectively, of a point located on the neutral axis of the beam. The shape function f is defined as a function of the variable z depending on the distribution of transverse shear stress through the thickness of the beam, and it is assumed to be zero at both the top and bottom surfaces of the beam.

According to the hyperbolic shear deformation beam theory, the non-zero normal strain (ε_x) and shear strain (γ_{zx}) observed at any point of the beam are associated with the unknown displacement parameters $\varepsilon_x^0, k_x^b, k_x^s, \gamma_{xz}^0$ which are defined in Equations (17) and (18) and presented in Equations (13), (14), (15), and (16) as follows.

$$\varepsilon_x = \varepsilon_x^0 + zk_x^b + fk_x^s \quad (13)$$

$$\gamma_{zx} = g\gamma_{zx}^0 \quad (14)$$

$$\varepsilon_x^0 = \frac{du_0}{dx} \quad (15)$$

$$k_x^b = -\frac{d^2w_0}{dx^2} \quad (16)$$

$$k_x^s = \frac{d\phi}{dx} \quad (17)$$

$$\gamma_{xz}^0 = 0 \quad (18)$$

The shape function f and its derivative, the function g , are defined in Equations (19) and (20).

$$f = \left[z - h \sinh\left(\frac{z}{h}\right) * z \cosh\left(\frac{1}{2}\right) \right] \quad (19)$$

$$g = f' = \left[1 - \cosh\left(\frac{1}{2}\right) \cosh\left(\frac{z}{h}\right) \right] \quad (20)$$

The stress-strain relationship at any point within the k-th layer of the beam is given by the one-dimensional Hooke's law in Equations (21), (22) and (23). (Soldatos et al., 1992).

$$\sigma_x^k = E^k(z)\varepsilon_x^k \quad (21)$$

$$\tau_{xz}^k = G^k(z)\gamma_{zx}^k \quad (22)$$

$$G^k(z) = \frac{E^k(z)}{2(1+\nu)} \quad (23)$$

1.3. Equations of Motion

Hamilton's principle is used to derive the equations of motion for functionally graded (FG) sandwich beams based on the hyperbolic shear deformation theory. In the case of FG sandwich beams, this principle represents the condition where the variations in the system's total energy are equal to zero.

$$\int_{t_1}^{t_2} (\delta U - \delta V + \delta K) dt = 0 \quad (24)$$

Here, δU , δV and δK represent the variations of the total strain energy, potential energy, and kinetic energy, respectively, while t_1 and t_2 denote the initial and final times. The variation of the strain energy is expressed by Equation (25).

$$\delta U = \int_0^L \int_{-\frac{b}{2}}^{\frac{b}{2}} \int_{-\frac{h}{2}}^{\frac{h}{2}} (\sigma_x^k \delta \varepsilon_x + \tau_{zx}^k \delta \gamma_{zx}) dz dy dx = \int_0^L \left(N_x \frac{d\delta u_0}{dx} - M^c \frac{d^2 \delta u_0}{dx^2} + M^s \frac{d\delta \phi}{dx} + Q \delta \phi \right) dx \quad (25)$$

This equation represents the variation of the strain energy of the beam. Here, N_x denotes the axial force; M^c represents the bending moment similar to that in classical beam theory; M^s is the higher-order moment associated with shear deformation; and Q denotes the shear force. These quantities are calculated by appropriately integrating the stresses developed throughout the thickness of the beam.

$$\begin{pmatrix} N_x \\ M^c \\ M^s \\ Q \end{pmatrix} = b \int_{-\frac{h}{2}}^{\frac{h}{2}} \begin{pmatrix} \sigma_x^k \\ \sigma_x^k z \\ \sigma_x^k f \\ \tau_{zx}^k f' \end{pmatrix} dz = \begin{bmatrix} A & B & C & 0 \\ B & D & E & 0 \\ C & E & F & 0 \\ 0 & 0 & 0 & H \end{bmatrix} \begin{pmatrix} \varepsilon_x^0 \\ k_x^b \\ k_x^s \\ \gamma_{zx}^0 \end{pmatrix} \quad (26)$$

The matrices A, B, C, D, E, F, and H are defined in Equation (27) and represent the geometric and mechanical properties of the beam. To construct matrices A, B, C, D, E, and F, a series of integrals are computed using the material properties and geometric information at a given cross-section.

These integrals represent the product of a density function, which depends on the material properties and the shape function, over the width of the beam. The process is carried out by performing integration along the length of the beam.

$$(A, B, C, D, E, F) = b \int_{-h/2}^{h/2} E^k(z) (1, z, f, z^2, fz, f^2) dz$$

$$H = b \int_{-h/2}^{h/2} G^k(z) g^2 dz \quad (27)$$

The variation of the potential energy, δV arises from the external loads acting on the beam and represents an important parameter in determining the beam's mechanical behavior. The potential energy of these external loads is expressed in terms of the displacements and stresses developed in the beam at the points where the loads are applied. In other words, the effect of the forces and moments acting on the beam, together with the material's elastic properties and geometry, governs the variation of the potential energy. The variation of the potential energy δV due to the load q and the axial force N_0 is given by Equation (28), and this expression provides a fundamental calculation for analyzing the elastic response of the beam under applied loads.

$$\delta V = \int_0^L \left(q \delta w + N_0 \frac{dw}{dx} \frac{d\delta w}{dx} \right) dx \quad (28)$$

The variation of the kinetic energy (δK) is obtained by Equation (29).

$$\begin{aligned} \delta K &= \int_0^L \int_{-b/2}^{b/2} \int_{-h/2}^{h/2} \rho(z) \left(\frac{d^2 u}{dt^2} \delta u + \frac{d^2 w}{dt^2} \delta w \right) dz dy dx \\ &= \int_0^L \left(I_A \frac{d^2 u_0}{dt^2} - I_B \frac{d^3 w_0}{dx dt^2} + I_C \frac{d^2 \phi}{dt^2} \right) \delta u_0 dx + \int_0^L \left(-I_B \frac{d^2 u_0}{dt^2} + I_D \frac{d^3 w_0}{dx dt^2} - I_E \frac{d^2 \phi}{dt^2} \right) \frac{d\delta w_0}{dx} dx \\ &\quad + \int_0^L \left(I_C \frac{d^2 u_0}{dt^2} - I_E \frac{d^3 w_0}{dx dt^2} + I_F \frac{d^2 \phi}{dt^2} \right) \delta \phi dx + \int_0^L I_A \frac{d^2 w_0}{dt^2} \delta w_0 dx \end{aligned} \quad (29)$$

Here, $\rho(z)$ represents the thickness-dependent mass density of each layer and is an important parameter in determining the dynamic behavior of the beam. The inertia moment coefficients I_A , I_B , I_C , I_D , I_E and I_F are defined by Equation (30) to quantitatively describe the beam's inertial properties and the effects of mass distribution on its vibration and motion. These coefficients are calculated by considering the density distribution and geometric parameters at different cross-sectional points of the beam and play a critical role in the dynamic analysis of the structure.

$$(I_A, I_B, I_C, I_D, I_E, I_F) = b \int_{-h/2}^{h/2} \rho^k(z) (1, z, f, z^2, fz, f^2) dz \quad (30)$$

When the coefficients of the variables δu_0 , δw_0 ve $\delta \phi_0$ are collected and set equal to zero, the equations of motion of the beam are derived. During this process, partial integration is applied to Equation (24); this allows the derivatives in the differential equations to be appropriately reduced and the integral form to be obtained while taking the boundary conditions into account. In this way, the general equilibrium equations related to the displacements and rotations of the beam are systematically formulated and become suitable for dynamic analysis.

$$\begin{aligned} \frac{dN_x}{dx} &= I_A \frac{d^2 u_0}{dt^2} - I_B \frac{d^3 w_0}{dx dt^2} + I_C \frac{d^2 \phi}{dt^2} \\ \frac{d^2 M^c}{dx^2} &= -q + N_0 \frac{d^2 w_0}{dx^2} + I_B \frac{d^3 u_0}{dx dt^2} - I_D \frac{d^4 w_0}{dx^2 dt^2} + I_A \frac{d^2 w_0}{dt^2} + I_E \frac{d^3 \phi}{dx dt^2} \\ \frac{dM^s}{dx} - Q &= I_C \frac{d^2 u_0}{dt^2} - I_E \frac{d^3 w_0}{dx dt^2} + I_F \frac{d^2 \phi}{dt^2} \end{aligned} \quad (31)$$

By substituting the stress resultants (N_x, M^c, M^s, Q) from Equation (28) into Equation (31), the following equations of motion can be obtained in terms of the unknown displacement variables (u_0, w_0, ϕ_0).

$$\begin{aligned} A \frac{d^2 u_0}{dx^2} - B \frac{d^3 w_0}{dx^3} + C \frac{d^2 \phi}{dx^2} &= I_A \frac{d^2 u_0}{dt^2} - I_B \frac{d^3 w_0}{dx dt^2} + I_C \frac{d^2 \phi}{dt^2} \\ B \frac{d^3 u_0}{dx^3} - D \frac{d^4 w_0}{dx^4} + E \frac{d^3 \phi}{dx^3} &= -q + N_0 \frac{d^2 w_0}{dx^2} + I_B \frac{d^3 u_0}{dx dt^2} - I_D \frac{d^4 w_0}{dx^2 dt^2} + I_A \frac{d^2 w_0}{dt^2} + I_E \frac{d^3 \phi}{dx dt^2} \\ C \frac{d^2 u_0}{dx^2} - E \frac{d^3 w_0}{dx^3} + F \frac{d^2 \phi}{dx^2} - H \phi &= I_C \frac{d^2 u_0}{dt^2} - I_E \frac{d^3 w_0}{dx dt^2} + I_F \frac{d^2 \phi}{dt^2} \end{aligned} \quad (32)$$

THEORETICAL RESULTS AND DISCUSSION

In this section, the results of the vertical displacement analyses of simply supported functionally graded porous sandwich beams using the hyperbolic shear deformation theory were obtained and compared with the literature. The face sheets of the sandwich beams are made of functionally graded (Al/Al_2O_3) material, while the core is made of homogeneous isotropic (Al) material. The beam length is taken as $L = 1\text{ m}$, while the beam thickness varies according to the aspect ratio. The properties of alumina (Al_2O_3) and aluminum (Al) materials are given in Table 1.

Table 1. Properties of alumina (Al_2O_3) and aluminum (Al) materials (Taşkın & Demirhan, 2020)

Malzeme Çeşidi	E (Gpa)	ρ (kg/m ³)	ν
Alümina (Al_2O_3)	380	3960	0.3
Alüminyum (Al)	70	2702	0.3

The layers used in the analyses and their corresponding height values h_0, h_1, h_2, h_3 are given in Table 2.

Table 2. Layer types and height value h_0, h_1, h_2, h_3

Tabaka çeşitleri	h_0	h_1	h_2	h_3
1-1-1	$-h/2$	$-h/6$	$h/6$	$h/2$
1-2-1	$-h/2$	$-h/4$	$h/4$	$h/2$
2-1-2	$-h/2$	$-h/10$	$h/10$	$h/2$
2-1-1	$-h/2$	0	$h/4$	$h/2$
2-2-1	$-h/2$	$-h/10$	$3h/10$	$h/2$
1-8-1	$-h/2$	$-2h/5$	$2h/5$	$h/2$

The numerical results obtained from the analysis were expressed using the following dimensionless form. The definitions in the dimensionless expression are as follows:

- Dimensionless Vertical Displacement

$$\bar{w} = \frac{w100E_m h^3}{q_0 L} \quad (33)$$

In the dimensionless vertical displacement defined by Equation (33), under the condition $x = L/2$ and $z = 0$; w represents the vertical displacement, E_m denotes the material's elastic modulus, h is the beam thickness, q_0 is the maximum intensity of the load at the center of the beam, and L is the beam length. (Sayyad & Avhad, 2019)

1.4. Investigation of Vertical Displacement Characteristics of FG Porous Sandwich

Beams

In this study, the vertical displacement behaviors of simply supported functionally graded (FG) porous and non-porous sandwich beams were investigated using the hyperbolic shear deformation theory. In the analyses, three different porosity ratios, $e=0$, $e=0.2$ and $e=0.4$, were considered. At this stage, the exponential parameter p , which defines the material distribution, was selected as $p=1$, $p=2$, and $p=10$, and the results were interpreted accordingly. For the examination of the beams, the L/h ratios were taken as 5 and 20. Furthermore, in order to enable structural comparisons, three different sandwich beam types Type A, Type B, and Type C were used.

Figure 3. Effect of e on the vertical displacement for different structure types at $p=10$ ($L/h=5$ and 20).

In Figure 3, the dimensionless vertical displacement behavior of simply supported functionally graded (FG) porous sandwich beams is presented as a function of porosity ratio (e) for different structure types (Type A, Type B, Type C) and two different L/h ratios (5 and 20) at the exponential parameter $p=10$. In all graphs, the displacement values increase noticeably as the porosity ratio increases. This increase is most pronounced in the Type A structure; in particular, configurations with less rigid cores, such as the 2-1-2 arrangement, exhibit the most susceptible deformation behavior. For example, for Type A with $L/h=5$ and $e=0.4$, the displacement in the 2-1-2 arrangement reaches approximately 71 units. Type B and Type C structures show more limited increases and exhibit stiffer behavior.

Moreover, at $p=10$, the pores are more concentrated in the surface layers, significantly reducing the bending stiffness of the structure and increasing deformation sensitivity. This effect becomes even more pronounced at high porosity ratios ($e=0.4$). Cases with $L/h=5$

generally exhibit higher displacement values compared to $L/h=20$, indicating that thicker beams are more sensitive to bending. As a result, these graphs clearly demonstrate the effect of both the pp parameter, which controls the pore distribution, and the structure type and layer arrangement on vertical displacement.

Figure 4. Effect of the p parameter and L/h ratio on the vertical displacement as a function of porosity ratio for the 1-8-1 layer configuration in the Type B structure.

In Figure 4. for the Type B structure with a 1-8-1 layer configuration, it is observed that the dimensionless vertical displacement values increase steadily as the pp parameter rises. This increase is due to the concentration of pores toward the surface, which reduces the structural stiffness and enhances the tendency for deformation.

Additionally, the displacement values obtained for $L/h=5$ are higher compared to $L/h=20$, indicating that shorter and thicker beams are more sensitive to bending deformation.

Figure 5. Displacement Behavior of Type B – 2-1-2 Layered Beam According to e and p Parameters ($L/h = 5$ and 20).

Figure 5. illustrates the variation of dimensionless vertical displacement of the 2- 1-2 layered beam with Type B configuration as a function of porosity ratio and the p parameter. As the porosity and p value increase, the displacement increases; however, when the L/h ratio rises, the displacement decreases.

CONCLUSION

In conclusion, the results clearly highlight the strong influence of porosity ratio, pore distribution parameter, structural type, and layer configuration on the bending behavior of FG porous sandwich beams. Higher porosity levels and larger values of the exponential parameter significantly reduce bending stiffness, leading to greater vertical displacements, especially in structures with less rigid cores such as the 2-1-2 arrangement.

Comparisons across L/h ratios further emphasize that shorter and thicker beams ($L/h=5$) are more prone to deformation than slender beams ($L/h=20$). Overall, the findings demonstrate that both geometric parameters and material gradation play a decisive role in governing the displacement response, providing important insights for the design of lightweight yet mechanically efficient sandwich structures.

ABSTRACT

Triply Periodic Minimal Surface (TPMS)-based lattice structures offer innovative material solutions for the aerospace, biomedical, automotive, and energy industries with their advantages of lightweight design, high strength-to-weight ratio, and multifunctional properties. This study comprehensively investigates the equivalent mechanical properties of TPMS structures through analytical models, parametric analyses, and literature data. The geometric characteristics of TPMS types such as Gyroid, Primitive, and I-WP, along with their smooth and continuous surface topologies, reduce stress concentrations and provide superior mechanical performance and fatigue resistance. Compared to conventional porous materials such as metal foams, honeycomb structures, and space frame systems, TPMS structures stand out with their ability to control isotropic/anisotropic behavior, high surface area-to-volume ratio, and optimized energy absorption capacity. In determining equivalent mechanical properties such as elastic modules, yield strength, and Poisson's ratio, analytical approaches like the Gibson-Ashby model are utilized to detail the power-law relationships between mechanical behavior and relative density (solid volume fraction). Parametric analyses reveal the influence of unit cell size, surface curvature, and porosity on mechanical performance and demonstrate that different TPMS topologies exhibit distinct responses even at the same relative density. This enables application-specific design optimization. The study provides a theoretical framework for the design and analysis of TPMS-based structures.

INTRODUCTION

Functionally Graded Materials (FGMs) are an advanced class of materials distinguished by a spatially varying composition throughout their volume, which leads to gradual changes in material properties tailored to meet specific functional requirements (Loh et al., 2018). The properties of functionally graded structures can vary based on porosity, composition, or microstructural distribution, enabling their broad application in fields such as aerospace, automotive, biomedical implants, and acoustics (Yu, Sun, & Bai, 2019; Mahmoud & Elbestawi, 2017; Lin et al., 2013). Theoretical investigation of FGMs involves issues such as material selection, structural design, and the optimization of structural performance (Solar, 2024). Despite these advantages, one of the primary obstacles in the development of FGMs is the difficulty of fabrication due to their gradually varying and complex internal structure, which limits their large-scale implementation. Besides the ordinary lattice structures, a newly emerging structure, triply periodic minimal surfaces (TPMS), has caught attention and boosted a specific research field. Triply periodic minimal surface (TPMS) structures, especially when

used in the inner layers, optimize load distribution and energy absorption characteristics (Solar, Demirhan, & Taskin, 2025). Compared with singly periodic and doubly periodic minimal surfaces, triply periodic minimal surfaces (TPMS) are mathematically defined structures that repeat in three dimensions with zero mean curvatures and large surface areas. (Yu, Sun, & Bai, 2019) So far, fabrication of mathematically defined TPMS cellular structures was mainly realized by AM technologies, due to their high complexity. (Yang et al., 2018) In general, studies in the current literature indicate that TPMS-based cellular structures not only offer outstanding performance comparable to other porous materials, including excellent energy absorption, low weight, high strength-to-weight ratio, and effective thermal and acoustic insulation, but also benefit from their inherent geometric advantages. Specifically, TPMS structures possess smooth surfaces and consistent curvature radii, which enhance their manufacturability via additive manufacturing processes thanks to their self-supporting nature. Moreover, compared to conventional strut-based cellular designs characterized by sharp edges and abrupt corners, TPMS geometries enable more biomimetic and structurally efficient designs (Kapfer et al., 2011; Mazur et al., 2016).

Among the various triply periodic minimal surface (TPMS) structures, Gyroid, Diamond, Primitive, and I-WP are widely studied due to their distinct geometric characteristics and mechanical behavior. The Gyroid surface, first described by Schoen (1970), is a non-self-intersecting minimal surface that divides space into two interpenetrating but non-overlapping labyrinths. It offers a balanced isotropic mechanical response, making it highly suitable for load-bearing biomedical implants (Shelef & Bar-On, 2021). The Diamond TPMS structure exhibits a more angular geometry with a lower surface-to-volume ratio compared to the Gyroid, and typically shows higher stiffness but reduced ductility under compression (Maskery et al., 2018). The Schwarz Primitive (P) surface, characterized by relatively flat and broad patches, supports a stretching-dominated deformation mechanism when implemented as a sheet-based TPMS structure, leading to enhanced stiffness and energy absorption compared to strut-based lattices—this is well-demonstrated in compressive performance studies (Lee et al., 2017; Zhang et al., 2018). On the other hand, TPMS topologies like the I-WP (Isotropic Woodpile) have been comparatively analyzed with other forms such as Förstner Random Dots (FRD), where FRD outperformed I-WP in terms of crashworthiness metrics such as specific energy absorption at low relative densities (Bunsri et al., 2024). Overall, these TPMS geometries allow precise tuning of porosity, mechanical anisotropy, and stress distribution, and when combined in hybrid or graded structures they offer significantly improved energy absorption and multifunctional performance (Xie et al., 2023).

The Gyroid, introduced by Schoen in 1970, is a chiral, non-self-intersecting minimal surface with no planar symmetry and no straight lines (Schoen, 1970). Its continuously smooth and periodic nature leads to relatively isotropic mechanical behaviour and has made Gyroid architectures attractive for load-bearing biomedical scaffolds; gyroid lattices often combine a balanced stiffness and energy-absorption capacity that can mimic trabecular bone mechanics (Yan, Hao, Hussein, & Young, 2015; Yang et al., 2019). Moreover, the gyroid's continuous shell geometry tends to be self-supporting in powder-bed fusion processes (e.g., SLM/LPBF), which improves manufacturability and can reduce the need for additional support structures (Yan et al., 2015; Yang et al., 2019).

The Primitive TPMS often features broader, flatter regions and larger open pores; depending on whether the topology is implemented as a sheet or as a skeletal (strut) form, it can show bending-dominated deformation and excellent energy-absorption characteristics, which is why Primitive-based designs are frequently proposed for impact-mitigation applications (Zhang et al., 2018; Chen et al., 2023). Build orientation, wall thickness and

relative density strongly affect the Primitive's manufacturability and mechanical response, so these processing/design variables must be explicitly reported in any technical claim.

The I-WP (Isotropic Woodpile) TPMS, originally introduced by Schoen (1970), exhibits a highly symmetric and interconnected topology characterized by smooth, continuous transitions and geometric regularity (Lee, Weber, & Yerger, 2024; Schoen, 1970). Investigations comparing the mechanical response of various TPMS forms under compression found that I-WP demonstrates deformation behaviour that lies between stretching- and bending-dominated regimes, offering a more balanced mechanical performance than forms like primitive or gyroid (Bunsri et al., 2024). These topological characteristics contribute to more uniform anisotropy control and homogeneous stress distribution — advantageous traits for structural applications. While explicit studies quantifying fatigue resistance or biocompatibility specific to I-WP are limited, the topology's continuity and interconnectedness suggest potential benefits in such domains, particularly for biomedical scaffolds, pending direct experimental validation.

To visually illustrate the geometric diversity and relative density distribution of Triply Periodic Minimal Surface (TPMS) structures, Figure 1 presents two main categories of TPMS lattices: sheet-based and solid-based types. These scaffold geometries, modeled at a relative density of 0.25, emphasize the topological differences in their spatial distribution and connectivity. While the sheet-type TPMS lattices consist of continuous thin walls forming open voids, the solid-type counterparts are defined by interconnected solid regions with periodic internal porosity. Such structural variations significantly influence mechanical properties, manufacturability, and suitability for application-specific performance requirements, particularly in biomedical and lightweight structural systems (Viet, Karathanasopoulos, & Zaki, 2022).

Figure 1. Schematic demonstration of various TPMS scaffolds having relative density of 0.25 with (a): Sheet type; (b): Solid type. (Viet, Karathanasopoulos, & Zaki, 2022)

Compared to conventional porous materials such as metal foams, honeycomb structures, and lattice frameworks, Triply Periodic Minimal Surface (TPMS) architectures offer significant improvements due to their mathematically defined, continuous geometries. While metal foams often suffer from irregular pore distributions and limited control over directional mechanical properties, TPMS lattices enable precise tuning of isotropic and anisotropic mechanical behavior, along with higher surface area-to-volume ratios and customizable deformation patterns (Ashby, 2006; Maskery et al., 2018). These features result in enhanced stiffness-to-weight ratios, superior energy absorption capabilities, and more predictable fatigue resistance.

Moreover, the inherent self-supporting nature of TPMS structures facilitates fabrication through advanced additive manufacturing methods such as laser powder bed fusion (LPBF), minimizing the need for support structures (Al-Ketan et al., 2018). Consequently, TPMS-based materials are increasingly favored for biomedical implants, aerospace components, and lightweight structural applications where mechanical efficiency and tailored responses are paramount.

Table 1 offers a comparative overview of various porous structure types including metal foams, honeycomb structures, space frame systems, and TPMS lattices highlighting key differences in porosity distribution, mechanical tunability, manufacturability, and application domains. This comparison underscores the superior versatility and performance potential of TPMS structures in advanced engineering applications.

Table 1. Comparison of Porous Structure Types

Property	Metal Foams	Honeycomb Structures	Space Frame Systems	TPMS Structures
Porosity Distribution	Random and non-uniform	Directional and layered	Structured and modular	Smooth and continuous
Isotropic/Anisotropic Control	Limited	Moderate	Customizable	Highly tunable
Surface Area-to-Volume Ratio	Moderate	Low	Moderate	High
Stress Concentration	High due to irregular cells	Present at nodes	High at joints	Minimized due to smooth topology
Energy Absorption	Moderate to High	Moderate	Variable	High and optimizable

Moreover, the intrinsic periodicity and mathematical definability of TPMS architectures enable precise computational modeling and simulation, which is particularly advantageous for predictive design workflows. Unlike stochastic foams and irregular honeycomb systems, TPMS lattices can be engineered with consistent mechanical responses across the structure, minimizing variability in load distribution and enhancing reliability in service conditions (Viet et al., 2022).

Additionally, many TPMS structures such as the Gyroid and I-WP exhibit inherent self-supporting characteristics that reduce or eliminate the need for auxiliary support structures during additive manufacturing processes like selective laser melting (SLM), leading to decreased material waste and reduced post-processing effort (Al-Ketan et al., 2018; Maskery et al., 2018). This advantage not only lowers production costs but also accelerates prototyping and customization, which is especially valuable for critical biomedical and aerospace components.

Given their tailorable mechanical anisotropy, seamless porosity gradation, and manufacturability advantages, TPMS-based designs are not just an alternative, but a paradigm shift in the field of architected materials. Their adoption continues to expand in areas demanding multifunctional performance—where stiffness, energy absorption, biological compatibility, and weight reduction must be simultaneously optimized (Al-Ketan et al., 2020).

The mechanical behavior of Triply Periodic Minimal Surface (TPMS) structures has been extensively studied due to their promising potential in lightweight and multifunctional engineering applications. Maskery et al. (2017) experimentally and numerically analyzed additively manufactured double Gyroid lattices, highlighting their energy absorption and failure modes. The foundational work by Ashby and Gibson (1997) on cellular solids provides a theoretical basis for understanding TPMS stiffness and strength characteristics. Additionally, Ngo et al. (2018) reviewed additive manufacturing technologies and discussed the advantages of TPMS architectures in aerospace and energy sectors due to their tunable mechanical properties and manufacturability. These studies collectively demonstrate the growing importance of TPMS lattices in advanced structural designs. A detailed comparison of key TPMS studies is shown in Table 2.

MATERIAL AND METHOD

1.5. Design and Geometric Generation of Lattice Architectures

A lattice structure is characterized by a repeating unit cell, where the solid volume V_{solid} is compared to the total volume V_{total} to determine the volume fraction:

$$Volume\ Fraction = \frac{V_{solid}}{V_{total}}$$

The lattice geometry directly influences this volume fraction, as it dictates the distribution of solid material within the unit cell (Chatzigeorgiou et al., 2021).

In this study, three distinct TPMS geometries Gyroid, Primitive, and I-WP were selected due to their widely recognized mechanical behavior and fabrication feasibility. Each unit cell was modeled using implicit surface equations in MATLAB within a cubic design domain $L \times L \times L$, with periodic boundary conditions. The isosurface parameter t was varied within the range $0 \leq t \leq 1.5$ to investigate the influence of relative density on mechanical properties.

1.6. Input parameters

This study employs two primary input parameters: the relative density (ρ_{rd}) and the type of TPMS unit cell. These parameters play a critical role in determining the effective mechanical response of the lattice structures. Different TPMS geometries, due to their unique surface topologies, exhibit varied stiffness, energy absorption, and anisotropy characteristics, even under the same RD value.

1.6.1. Relative Density

The relative density (ρ_{rd}) is a dimensionless parameter that represents the ratio of the apparent density of a cellular structure to the density of its solid parent material. It is defined as follows:

$$\rho_{rd} = \frac{\rho^*}{\rho_s}$$

The ρ_{rd} governs many mechanical properties such as stiffness, strength, and energy absorption capacity. As the RD increases, stiffness and strength generally increase at the cost of weight savings and energy absorption efficiency. In this study, ρ_{rd} is controlled via the isosurface parameter (t) in the implicit mathematical formulations of TPMS geometries, allowing continuous gradation and fine-tuning of porosity across the structure.

1.6.2. Unit Cells

The unit cell represents the fundamental building block that is periodically repeated to form a complete lattice structure. Depending on their geometry, unit cells can be categorized into various types. In TPMS-based lattice architectures, the unit cell geometry is mathematically described using implicit equations that involve trigonometric functions.

In the current study, three distinct TPMS topologies Gyroid, Primitive, and I-WP were examined. These structures were selected due to their continuous curvature, high surface-to-volume ratio, and self-supporting capabilities, which make them suitable for additive manufacturing and mechanical performance optimization. The mathematical formulations used to define their implicit surfaces are detailed in the subsequent section.

Gyroid

$$t = \sin\left(\frac{2\pi x}{L}\right) * \cos\left(\frac{2\pi y}{L}\right) + \sin\left(\frac{2\pi y}{L}\right) * \cos\left(\frac{2\pi z}{L}\right) + \sin\left(\frac{2\pi z}{L}\right) * \cos\left(\frac{2\pi x}{L}\right)$$

Primitive

$$t = \cos\left(\frac{2\pi x}{L}\right) + \cos\left(\frac{2\pi y}{L}\right) + \cos\left(\frac{2\pi z}{L}\right)$$

I-WP

$$t = \cos\left(\frac{2\pi x}{L}\right) * \sin\left(\frac{2\pi y}{L}\right) + \cos\left(\frac{2\pi y}{L}\right) * \sin\left(\frac{2\pi z}{L}\right) + \cos\left(\frac{2\pi z}{L}\right) * \sin\left(\frac{2\pi x}{L}\right)$$

1.6.3. Porosity–Modulus Models

Various models have been developed to describe the mechanical behavior of porous materials, particularly focusing on how the elastic modulus decreases with increasing volume porosity. While some models assume a linear relationship, others incorporate more complex power-law or exponential functions. These expressions vary in accuracy depending on microstructural features such as pore shape, distribution, and connectivity.

The following table summarizes these approaches, presenting their general forms and main characteristics. It serves as a comparative reference for researchers working on porous structures such as TPMS lattices (Table 3; Silver-Thorn, 2013).

Table 3. Comparison of Models Describing the Relationship Between Porosity and Elastic Modulus. (Silver-Thorn, 2013)

General equation form			
Linear equations	Power equations	Exponential equations	Other equations
$\frac{E_p}{E_0} = 1 - aP$	$\frac{E_p}{E_0} = (1 - jP)^i$	$\frac{E_p}{E_0} = \exp(-mP)$	$\frac{E_p}{E_0} = (1 - P)/(1 + wP)$
	$\frac{E_p}{E_0} = 1 - uP^{2/3}$	$\frac{E_p}{E_0} = 1 - \exp(-r(1 - P))$	$\frac{E_p}{E_0} = 1 + \left[\frac{AP}{1 - AP - P}\right]$
	$\frac{E_p}{E_0} = \left[1 - \left(\frac{P}{Q}\right)\right]^{KQ}$	$\frac{E_p}{E_0} = \exp[-(nP + gP^2)]$	$\frac{E_p}{E_0} = (1 - P^2)/(1 + yP)$
	$\frac{E_p}{E_0} = (1 - P^{2/3})^{1.21S}$		
	$\frac{E_p}{E_0} = (1 - P^{2/3})/(1 - P^{2/3} + P)$		
	$\frac{E_p}{E_0} = 1 - dP + gP^2$		
	$\frac{E_p}{E_0} = \left[1 - \left(\frac{P}{t}\right)\right]^s$		

1.1.1. Gibson–Ashby Model

The Gibson–Ashby model is widely used to predict the equivalent mechanical properties of porous and cellular materials, including TPMS lattice structures. In this study, Young's modulus (E), shear modulus (G), and Poisson's ratio (ν) are expressed as functions of relative density (ρ_{rd}) for different TPMS geometries Maskery et al. (2018).

The general form of the Gibson–Ashby equations is expressed as:

$$E^* = C_E x E_s \times \rho_{rd}^{n_E}$$

$$G^* = C_G x E_s \times \rho_{rd}^{n_G}$$

$$\nu^* = f(\rho_{rd})$$

The following table presents the piecewise analytical expressions for the effective elastic modulus (E^*), shear modulus (G^*), and Poisson's ratio (ν^*) of the Gyroid TPMS structure as a function of the relative density (ρ_{rd}), based on the study by Maskery et al. (2018).

Table 4. Mechanical properties of sheet-based TPMS structures

Mechanical Property	Condition	Expression
Gyroid (G)	$\rho_{rd} \leq 0.45$	$\frac{E^*}{E_s} = 0.596 \times \rho_{rd}^{1.467}$
	$\rho_{rd} > 0.45$	$\frac{E^*}{E_s} = (0.962 \times \rho_{rd}^{2.351} + 0.038)$
	$\rho_{rd} \leq 0.45$	$\frac{G^*}{G_s} = 0.777 \times \rho_{rd}^{1.544}$
	$\rho_{rd} > 0.45$	$\frac{G^*}{G_s} = 0.973 \times \rho_{rd}^{1.982} + 0.027$
	$\rho_{rd} \leq 0.5$	$\nu^* = 0.192 \times e^{-1.349 \times \rho_{rd}} + 0.202$
	$\rho_{rd} > 0.5$	$\nu^* = 0.402 \times \rho_{rd}^2 - 0.603 \times \rho_{rd} + 0.501$
Primitive (P)	$\rho_{rd} \leq 0.25$	$\frac{E^*}{E_s} = 0.317 \times \rho_{rd}^{1.264}$
	$\rho_{rd} > 0.25$	$\frac{E^*}{E_s} = 1.007 \times \rho_{rd}^{2.006} - 0.007$
	$\rho_{rd} \leq 0.25$	$\frac{G^*}{G_s} = 0.705 \times \rho_{rd}^{1.189}$
	$\rho_{rd} > 0.25$	$\frac{G^*}{G_s} = (0.953 \times \rho_{rd}^{1.715} + 0.047)$
	$\rho_{rd} \leq 0.55$	$\nu^* = 0.314 \times e^{-1.004 \times \rho_{rd}} + 0.119$
	$\rho_{rd} > 0.55$	$\nu^* = 0.152 \times \rho_{rd}^2 - 0.235 \times \rho_{rd} + 0.383$
I-graph and wrapped package-graph (IWP)	$\rho_{rd} \leq 0.35$	$\frac{E^*}{E_s} = 0.597 \times \rho_{rd}^{1.225}$
	$\rho_{rd} > 0.35$	$\frac{E^*}{E_s} = (0.987 \times \rho_{rd}^{1.782} + 0.013)$
	$\rho_{rd} \leq 0.35$	$\frac{G^*}{G_s} = 0.529 \times \rho_{rd}^{1.287}$
	$\rho_{rd} > 0.35$	$\frac{G^*}{G_s} = (0.960 \times \rho_{rd}^{2.188} + 0.040)$
	$\rho_{rd} \leq 0.13$	$\nu^* = 2.597 \times e^{-1.004 \times \rho_{rd}} - 2.244$
	$\rho_{rd} > 0.13$	$\nu^* = 0.201 \times \rho_{rd}^2 - 0.227 \times \rho_{rd} + 0.326$

RESULTS AND DISCUSSION

In this study, three different types of TPMS (Triply Periodic Minimal Surface) structures were utilized: Gyroid, I-WP and Primitive. For each TPMS topology, the relative densities were computed as a function of the isosurface threshold parameter (t). Subsequently, the corresponding effective mechanical properties, namely Young's modulus (E^*), shear modulus (G^*), and Poisson's ratio (ν^*), were determined. The variation of these mechanical properties with respect to t was investigated in detail within the range of $0 \leq t \leq +1.5$ for each TPMS type. These results provide a comprehensive comparison of the mechanical performance of the selected TPMS geometries across different porosity levels.

In order to evaluate the effective mechanical properties of TPMS-based lattice structures, a computational framework was implemented using MATLAB. Three types of TPMS topologies Gyroid, Primitive and I-WP were investigated over a predefined range of isosurface threshold values (t) between 0 and 1.5, divided into 60 equal intervals.

Once ρ_{rd} was determined for each t value and topology, the corresponding mechanical properties Young's modulus (E^*), Shear modulus (G^*), and Poisson's ratio (ν^*) were calculated using empirical Gibson–Ashby-type models. These models relate normalized mechanical properties to relative density using power-law or piecewise analytical expressions derived from the literature.

Figure 3 illustrates the variation of normalized modulus and relative density for three different TPMS structures. Subfigure (a) shows how the normalized modulus changes with relative density, highlighting the differences in stiffness among Primitive, Gyroid and I-WP geometries. Subfigure (b) presents the effective Young's modulus as a function of TPMS volume fraction, emphasizing how each structure responds differently to increasing porosity.

Figure 3. a) Variation of Normalized Young's Modulus with Relative Density for Different TPMS Structures b) Variation of the Effective Young's Modulus with volume fraction for different TPMS structures.

Figure 4. a) Variation of Normalized Young's Modulus with ρ for different TPMS structures b) Variation of the normalized shear modulus with ρ for different TPMS structures c) Variation of the Poisson ratio with ρ for different TPMS structures.

Figure 5. Three-dimensional surface plots of the relative density ρ for three different TPMS structures (Gyroid, I-WP, and Primitive) as a function of the isosurface parameter t and wall thickness.

Figure 6. Variation of Normalized Young's Modulus with Isosurface Threshold (t) for Different TPMS Structures

This figure illustrates the variation of normalized Young's modulus (E/E_s) as a function of the isosurface threshold parameter t for three distinct Triply Periodic Minimal Surface (TPMS) architectures: Primitive, Gyroid, and I-WP. The threshold t regulates the solid volume fraction within the unit cell, directly influencing the relative density and mechanical stiffness of each structure.

Comparison of Structures:

- The I-WP structure exhibits the highest normalized Young's modulus across the threshold range, indicating superior stiffness and load-bearing capability compared to the other two TPMS geometries.
- The Gyroid structure follows a moderately steep trend, showing intermediate stiffness values, reflecting its balance between flexibility and structural rigidity.
- The Primitive structure demonstrates the lowest normalized Young's modulus throughout, suggesting a more compliant and flexible lattice design.
- All three TPMS structures display nonlinear growth of stiffness with increasing t , consistent with the predictions of cellular solid models such as the Gibson–Ashby theory.

This analysis highlights that by adjusting the threshold t and selecting appropriate TPMS geometries, it is possible to tailor the elastic properties of architected and functionally graded materials for specific mechanical requirements.

Figure 7. Variation of Normalized Shear Modulus with Isosurface Threshold (t) for Different TPMS Structures

This figure illustrates the variation of the normalized shear modulus G/G_s for three TPMS structures—Primitive, Gyroid, and I-WP as a function of the isosurface threshold parameter t , which controls the relative density (prd) of each structure.

Threshold Parameter (t): The t parameter ranges from 0 to 1 and regulates the solid volume fraction of the unit cell. As t increases, the relative density of the structure increases, leading to enhanced mechanical stiffness.

Normalized Shear Modulus (G/G_s): The vertical axis represents the shear modulus of the TPMS structures normalized by the shear modulus of the solid material (G_s). This provides a measure of the relative stiffness of the porous structures.

Comparison of Structures:

- **Primitive (red solid line):** Exhibits moderate shear modulus values throughout the range of t , indicating intermediate stiffness.
- **Gyroid (blue dashed line):** Shows slightly higher shear modulus than Primitive for most values of t , reflecting better shear resistance.
- **I-WP (green dashed line):** Demonstrates the lowest normalized shear modulus, making it the most flexible structure among the three.

Trend: For all structures, G/G_s increases monotonically with t , confirming that higher relative density enhances the shear stiffness. The difference between structures becomes more pronounced at intermediate t values, while they converge at high t near 1, indicating that denser configurations reduce structural performance differences.

Figure 8. Variation of Poisson's Ratio with Isosurface Threshold (t) for Different TPMS Structures

This graph illustrates how the Poisson's ratio (ν) of three different TPMS (Triply Periodic Minimal Surface) structures—Primitive, Gyroid, and IWP—varies with the isosurface threshold parameter (t). The parameter ' t ' directly influences the relative density of the structure. Key observations from the graph:

Key Observations

- **Overall Trend:** For the Primitive and Gyroid structures, the Poisson's ratio generally decreases as the threshold ' t ' increases. This indicates that at higher densities, these materials exhibit reduced lateral expansion when subjected to axial strain. The IWP structure shows a slight decrease initially before starting to increase again after a ' t ' value of approximately 0.5.
- **Primitive Structure:** The Primitive structure consistently maintains the highest Poisson's ratio values across the entire range of ' t '. This behavior suggests a more ductile and flexible response compared to the other two structures.
- **Gyroid Structure:** The Gyroid structure exhibits a lower Poisson's ratio than the Primitive structure, and it shows a noticeable decrease as ' t ' increases. This suggests the material becomes less deformable in the lateral direction.
- **IWP Structure:** The IWP structure shows the lowest Poisson's ratio up to a ' t ' value of around 0.2. This indicates a more rigid behavior in the lateral direction. After this point, the Poisson's ratio begins to increase.
- **Non-linear Trends:** The non-linear trends observed for each structure reflect the strong dependence of the Poisson's ratio on the specific micro-geometry and density distribution.

These results are crucial for designing materials where specific mechanical properties, such as lateral stiffness or flexibility, are desired. This is particularly relevant in fields like biomechanics, aerospace panels, or flexible protective layers, where precise material behavior is essential for performance.

CONCLUSION

In this study, the mechanical behavior of three TPMS architectures Primitive, Gyroid, and I-WP was investigated as a function of the isosurface threshold parameter t . The analyses revealed that increasing t enhances relative density and, consequently, both elastic and shear stiffness. Among the structures, the I-WP exhibited the highest stiffness, followed by the Gyroid, while the Primitive consistently showed the lowest values, indicating higher flexibility. Poisson's ratio results showed a general decrease with increasing density, with the Primitive maintaining greater lateral deformability and the I-WP displaying the most rigid response. These findings confirm that by tuning the threshold parameter and selecting suitable TPMS geometries, mechanical properties can be effectively tailored for advanced engineering applications.

ABSTRACT

The valorization of non-edible carob pods (*Ceratonia siliqua* L.), an abundant resource in Algeria, represents a promising pathway for producing high value-added carbon materials. In this work, a mesoporous activated carbon was prepared from this biomass through phosphoric acid impregnation followed by controlled pyrolysis. The obtained material was characterized by thermogravimetric and differential scanning calorimetry analyses (TGA/DSC), X-ray diffraction (XRD), Fourier-transform infrared spectroscopy (FTIR), and specific surface area measurements (BET). The results revealed efficient carbonization between 300 and 450 °C, enhanced by the catalytic action of H₃PO₄, leading to an amorphous and highly porous structure. The activated carbon exhibited a high specific surface area (739.26 m²/g), a mesoporous structure confirmed by an H4-type hysteresis loop, and an abundance of oxygenated functional groups favorable for adsorption. These properties provide the material with strong potential for environmental applications such as pollutant adsorption, catalysis, and filtration.

Keywords : Carob tree, activated carbon, chemical activation, porosity, environmental applications

INTRODUCTION

The carob tree (*Ceratonia siliqua* L.), belonging to the family Caesalpiniaceae, is a typical species of Mediterranean regions. Cultivated for ornamental, industrial, and agro-silvo-pastoral purposes, it has considerable socio-economic and ecological importance due to its strong ability to adapt to arid and semi-arid conditions (Rejeb, 1989; Girolamo et al., 2002). Its pods, mainly used in the pharmaceutical and food industries (Van Uden, 1981; Maria et al., 1997), represent an abundant and low-cost resource, yet still largely underexploited.

In North Africa, and particularly in northern Algeria, certain varieties of carob trees produce non-edible pods. The valorization of these residues represents a promising opportunity for the production of high value-added carbon materials. In particular, their transformation into biochar or activated carbon fits within the framework of a circular economy, combining sustainable management of agricultural waste, improvement of soil quality, and contribution to the fight against climate change. Owing to their lignocellulosic structure, these biomasses are

well suited for carbonization and chemical activation, leading to the formation of porous materials characterized by high specific surface area, good thermal stability, and a richness in oxygenated functional groups. These properties provide activated carbon derived from carob with remarkable potential for contaminant adsorption and various environmental applications.

Beyond its technical performance, the use of non-edible carob pods presents several advantages, including local availability, low cost, renewable nature, and non-toxicity. This valorization also contributes to local socio-economic development through the creation of income-generating activities, while reducing the environmental impact associated with the accumulation of such residues (Mahmoud et al., 2014).

In this context, the present study aims to explore the potential of non-edible carob pods as a raw material for the preparation of mesoporous activated carbon by chemical activation. The focus will be on the physicochemical characterization of the obtained material and the evaluation of its properties for environmental applications.

MATERIAL AND METHOD

Preparation of Activated Carbon from *Ceratonia siliqua* Pods

The pods of *Ceratonia siliqua*, collected in Constantine (Algeria) during the month of December, were carefully rinsed with tap water and then with distilled water to remove impurities. They were subsequently dried at 50 °C until a constant weight was obtained. The dried material was then ground and sieved to obtain particles with a diameter ranging between 160 and 500 µm.

Twenty grams of this powder were impregnated with 10 g of 85% phosphoric acid for 24 hours at room temperature. The mixture was then subjected to a two-step sonication process: a first phase of 30 minutes under ultrasound, followed by a one-hour rest period, and then a second phase of 30 minutes under ultrasound.

The resulting product was dried at 110 °C for 24 hours and then placed in a furnace at room temperature. Carbonization was carried out at a heating rate of 9 °C/min until reaching 450 °C, a temperature maintained for one hour. The carbonized residue was then purified by continuous washing with distilled water in a Soxhlet extractor until the effluent was free of phosphate traces.

Finally, the obtained activated carbon was dried at 100 °C until its mass stabilized, finely ground, and stored in a hermetically sealed glass container.

Characterization of Activated Carbon

Thermal Analysis (TGA/DSC)

The thermal analysis of the sample was carried out using a simultaneous thermal analyzer TGA/DSC 3+ (Mettler Toledo), capable of reaching temperatures up to 1600 °C. The measurements were performed under a controlled nitrogen atmosphere, with a constant heating

rate of 10 °C/min, from room temperature up to 1000 °C. This analysis allowed the evaluation of the thermal stability of the sample, the identification of decomposition stages, and the characterization of mass losses (TGA) as well as the associated thermal transitions (DSC).

Specific Surface Area Analysis (BET)

The textural characterization of the activated carbon was carried out using a specific surface area analyzer AutosorbiQ Station 2 (Quantachrome Instruments), with nitrogen as the adsorbate gas at liquid nitrogen temperature (77.35 K). The sample, with a mass of 0.317 g, was previously degassed under vacuum at 200 °C for 9 hours in order to remove moisture and surface-adsorbed gases. The Brunauer-Emmett-Teller (BET) model was applied to calculate the specific surface area from the obtained adsorption isotherm.

X-Ray Diffraction (XRD) Analysis

The crystalline structural analysis of the carbon material was carried out by X-ray diffraction using an Empyrean diffractometer (PANalytical) equipped with a copper anode, producing radiation characterized by wavelengths $K\alpha_1 = 1.54060 \text{ \AA}$, $K\alpha_2 = 1.54443 \text{ \AA}$, and $K\beta = 1.39225 \text{ \AA}$, with a $K\alpha_2/K\alpha_1$ ratio of 0.5. The generator was set at 40 kV and 30 mA to ensure a stable intensity of the incident beam.

The scanning covered an angular range from 5.00° to 89.98° (2 θ), with a step size of 0.013° in continuous mode, and was performed at room temperature.

Fourier Transform Infrared (FTIR) Spectroscopy Analysis

Fourier Transform Infrared (FTIR) spectroscopy was performed on our sample using a Bruker INVENIO-X spectrometer equipped with an RT-DLaTGS detector. Measurements were carried out in the spectral range of 4000 to 400 cm⁻¹, with a resolution of 4 cm⁻¹ and 16 scans.

RESULTS AND DISCUSSION

Thermal Analysis (TGA/DSC)

The thermal behavior of the activated carbon as a function of temperature is shown in Fig. 1.

The TGA/DSC analysis shows that the sample activated at 450 °C with 10% phosphoric acid undergoes thermal transformation in several well-defined stages, typical of an efficient chemical activation process. The significant mass loss and intense exothermic effect observed between 300 and 450 °C indicate effective carbonization with the development of porosity. Phosphoric acid (H₃PO₄) plays a catalytic role in thermal degradation and contributes to the formation of porous structures stabilized at high temperature.

Fig. 1. Combined TGA and DSC curves of the analyzed activated carbon sample.

FTIR Analysis

The FTIR spectrum of the obtained activated carbon is presented in Fig. 2. It reveals the presence of various functional groups on the surface of the material, consistent with chemical activation using phosphoric acid. A broad band at 3410 cm^{-1} indicates the presence of hydroxyl (O–H) groups, potentially associated with phenolic or carboxylic groups, as well as adsorbed water (Zhang et al., 2020). A weak intensity at 2915 cm^{-1} suggests aliphatic (C–H) groups such as methyl or methylene groups (Ahuja et al., 2022). The band at 1710 cm^{-1} corresponds to carbonyl (C=O) groups, while the bands between $1580\text{--}1600\text{ cm}^{-1}$ and $1050\text{--}1250\text{ cm}^{-1}$ are attributed respectively to aromatic C=C bonds and C–O bonds (alcohols, acids, esters, ethers) (Mohamad et al., 2020). Finally, the peaks between $800\text{--}870\text{ cm}^{-1}$ confirm the presence of aromatic rings (=C–H).

This spectral profile, typical of chemically activated carbon, highlights the abundance of oxygenated functional groups, which significantly contribute to its adsorption properties (Esmail M et al., 2024).

Fig. 2. FTIR spectra of the activated carbon sample.

XRD Analysis

The X-ray diffraction (XRD) pattern of the activated carbon obtained after activation is shown in Fig. 3. It highlights a predominantly amorphous structure. A broad and low-intensity halo centered around $2\theta \approx 22-26^\circ$ is characteristic of amorphous or poorly crystallized carbon, which is typical of activated carbons derived from biomaterials treated at moderate temperatures ($<600^\circ\text{C}$) (Theeradit, Ph). A second broadening around $2\theta \approx 43^\circ$ suggests local graphitic rearrangements without the complete formation of graphene or well-ordered graphite.

Fig. 3. XRD patterns of the activated carbon sample.

The absence of sharp and narrow peaks, as well as the lack of high-intensity secondary peaks, indicates a low degree of crystallinity and the absence of significant crystalline mineral phases (such as quartz or calcite) or metallic oxides. These observations confirm that the activated carbon obtained has a disordered structure, optimized for applications requiring high specific surface area and well-developed porosity.

BET Analysis

The nitrogen adsorption isotherm at 77 K for the activated carbon is shown in Fig. 4.

The BET equation with an infinite number of layers was used to determine the specific surface area:

$$\frac{V}{V_m} = \frac{Cx}{(1-x)(Cx + 1 - x)}$$

Where $x = \frac{P}{P_0}$ represents the ratio of the equilibrium adsorption pressure P to the saturation vapor pressure of the gas P_0 . V is the volume of adsorbed gas under standard conditions (0 °C and 760 mmHg). V_m is the volume of gas under standard conditions required to cover the adsorbent with a monolayer. C is a constant characteristic of the isotherm.

The linear form of the BET equation can be written as:

$$\frac{x}{V(1-x)} = \frac{1}{V_m C} + \frac{C-1}{V_m C} x$$

By plotting $\frac{x}{V(1-x)}$ as a function of x , a straight line is obtained, with a slope of $\frac{C-1}{V_m C}$ and an intercept corresponding to $\frac{1}{V_m C}$. From these values, V_m can be calculated.

In our case, the following results were obtained:

$$\frac{1}{V_m C} = 8.76 \times 10^{-5} \text{cm}^{-3}$$

$$\frac{C-1}{V_m C} = 5.8 \times 10^{-3} \text{cm}^{-3}$$

$$\frac{1}{V_m} = \frac{C-1}{V_m C} + \frac{1}{V_m C} = 8.76 \times 10^{-5} + 5.8 \times 10^{-3} = 5.8876 \times 10^{-3} \text{cm}^{-3}$$

$$V_m = 169.848 \text{ cm}$$

The specific surface area was determined using the following relation:

$$S = \frac{V_m \cdot NA \cdot \sigma}{22414}$$

Where

$NA = 6.022 \times 10^{23}$ (Avogadro's number),

$\sigma = 0.162 \text{ nm}^2$ (area occupied by one nitrogen molecule),

22414 = molar volume in cm^3/mol (STP).

Thus, the specific surface area is:

$$S = 739.26 \text{ m}^2 \text{g}^{-1}$$

This result indicates a high specific surface area, characteristic of a highly porous material, suitable for applications requiring a large exchange surface, such as adsorption, catalysis, and filtration.

The nitrogen adsorption-desorption isotherm exhibits an H4-type hysteresis loop, typical of mesoporous materials with slit-shaped or lamellar pore structures. This behavior confirms the presence of non-uniform mesopores, possibly resulting from irregular particle stacking or specific chemical activation.

CONCLUSION

This work has demonstrated the feasibility of producing mesoporous activated carbon from non-edible carob pods, a locally available and low-cost biomass. Chemical activation with phosphoric acid and carbonization at 450 °C led to a material with a high specific surface area ($739.26 \text{ m}^2 \text{g}^{-1}$), an amorphous structure, and well-developed porosity, as confirmed by TGA/DSC, XRD, FTIR, and BET analyses.

These results highlight the potential of carob as an alternative resource for the production of sustainable activated carbons, suitable for adsorption and environmental treatment

applications. Beyond the scientific and technological interest, this valorization also contributes to agricultural waste management and the development of a circular economy at the regional level. Further studies will be necessary to evaluate the performance of this material in specific applications, particularly in the removal of organic and metallic pollutants from wastewater.

ABSTRACT

Bolting in spinach is an undesirable physiological process in which the plant suddenly transitions from the leaf formation period to the flowering period. This process leads to economic losses by negatively affecting leaf yield and market quality. The bolting process is determined by genetic predisposition and environmental conditions. Genetically, some spinach varieties are more resistant to bolting than others. This highlights the role of genes regulating flowering in bolting-related genes such as *Flowering Locus T*, *Leafy (LFY)* and *Suppressor of overexpression of co1 (SOC1)*. These loci controlling bolting are directly or indirectly stimulated under specific environmental and endogenous conditions and initiate flowering by generating a series of internal signals. Environmental factors that accelerate bolting include long day length (photoperiod), high temperatures, and gibberellin, an endogenous hormones and key factor of spinach bolting-related genes. Additionally, environmental stresses, such as nutrient imbalance and water stress, can trigger this process. Understanding these factors is important for developing bolting-tolerant genotypes through breeding studies and for achieving sustainable production. In addition to cultural measures, such as selecting an appropriate sowing time, using late-bolting varieties, and managing temperature and light, controlling bolting in spinach requires a holistic approach that includes genetic selection and carefully managing environmental conditions. This review examines the mechanisms related to genetic and environmental factors that trigger bolting and provides a perspective on research and development trends and application prospects in this field.

Keywords: Bolting, Climate change, High temperature, Spinach

INTRODUCTION

Spinacia oleracea (spinach), a species of green leafy vegetable in the *Amaranthaceae* family, has been documented in the Plant List database and has a history dating back more than 2000 years to ancient Persia. Spinach's remarkable adaptability to diverse climates and its extensive versatility in various culinary preparations have contributed to its widespread cultivation around the globe (Koh et al., 2012; van Treuren et al., 2012; Xu et al., 2017). Spinach, a widely cultivated and consumed vegetable in different parts of the world, is a vital source of nutrients. It is rich in vitamins (group B, β -carotene (provitamin A), folates, and C, etc.), minerals, and antioxidants. Spinach is also a prominent vegetable with high iron content (van Treuren et al. 2012; Koh et al. 2012; Niu et al. 2023). Beyond its nutritional importance, spinach cultivation significantly supports global agriculture, contributing to the livelihoods of many farmers. Furthermore, depending on the variety type and environmental conditions,

spinach yields have been reported to range from 18.6 to 44.8 tons per hectare (Kuwahara et al. 2014; Safdar et al. 2022; Niu et al. 2023). According to data from 2024, the global production of spinach was approximately 34 million tons, while Turkey's production was approximately 237 thousand tons. Following China, which is the global leader, countries such as the USA, India, and Turkey are significant producers (Fao, 2024; Tük, 2024). In this context, spinach is a pivotal vegetable type in terms of both enhancing production values and augmenting nutritional richness.

Climatic conditions represent a pivotal factor in the successful cultivation of spinach. As a cool climate vegetable, spinach exhibits a natural resistance to cold temperatures. However, this varies depending on the variety. With respect to soil, spinach can be cultivated in a variety of soil types; however, the interaction between soil characteristics and environmental conditions is a critical factor in determining successful cultivation outcomes. Therefore, in order to obtain a high-quality yield from a given unit area, it is essential to consider climate conditions, soil characteristics, and the selection of varieties resistant to environmental changes in spinach cultivation (Mutlu et al., 2016). In this context, the establishment of novel spinach breeding programs is imperative to cultivate new varieties that exhibit distinct morphological characteristics, including leaf texture, color, shape, posture, and petiole length. These characteristics are crucial for ensuring the resilience of the plants to fluctuating climatic and environmental conditions, in addition to meeting the evolving demands of the market. Indeed, extensive day exposure within breeding programs has been demonstrated to exert a substantial influence on numerous morphological characteristics, including but not limited to plant height and stem emergence. Consequently, it has been established that spring and summer spinach varieties exhibit a heightened propensity for flowering, resulting in a substantial decline in productivity (van Treuren et al. 2017; van Treuren et al. 2020; Cho et al. 2017).

The process of flowering and the early emergence of stems in spinach are among the most critical productivity-related traits, which are subject to the regulation of multiple signaling pathways and regulatory mechanisms (Arif et al., 2013; Chen et al., 2019). In recent years, significant advancements have been made in the field of flowering-related gene pathways and their molecular functions, particularly in model plants. However, there is a paucity of research focusing on the subject in spinach (Lee and An, 2015; Chitwood et al., 2016; Ma et al., 2016). This review will examine the molecular and environmental mechanisms that trigger flowering and emergence in spinach in the light of current studies. Additionally, it will offer insights into the current state of research, development trends, and potential applications in this domain.

WHAT IS BOLTING (FLOWERING AND EARLY EMERGENCE) IN SPINACH?

The yield of spinach cultivated in this manner is contingent upon numerous factors that must be meticulously evaluated during agronomic practices. As posited by van Treuren et al. (2017), the aforementioned factors encompass environmental variables, including temperature, light exposure, water, moisture, nutrition, and stress factors. Among the influential factors for spinach yield, early bolting/flowering is one of the most well-known important phenomena. Bolting, the premature onset of flowering and subsequent seed development in spinach plants, is a phenomenon that can lead to undesirable changes in the leaf flavor profile, including bitterness. Bolting has also been demonstrated to result in a reduction in plant leafing, thereby further reducing overall yield potential (Cho et al. 2017; Chen et al. 2019).

Spinach exhibits distinct bolting habits, categorized as follows: 'early bolting' (bolting 60 days after sowing), 'medium' (bolting 60-70 days after sowing), and 'late bolting' (bolting 70

days after sowing) (Chitwood et al. 2016). According to Kuwahara et al. (2014), spinach varieties commonly used in East Asia are known as early bolting varieties, while those used in Europe are usually late bolting varieties. The differences between Asian and Western spinach varieties are thought to be important for two reasons. The first section will address the origin and historical development of spinach, while the second will focus on the cultural and gustatory preferences of the populations inhabiting these two regions. Easterners have a marked preference for spinach varieties that exhibit smooth, narrow leaves and long petioles, while Westerners demonstrate a clear predilection for those varieties characterized by wrinkled leaves (Van der Vossen, 2004). Subsequent studies have reported the link between wrinkled leaves and late bolting in spinach (Sabaghnia et al., 2014; Kuwahara et al., 2014; Xu et al., 2017; Abolghasemi et al., 2021). This information can be used to improve the selection of varieties with late bolting as well as better economic performance under different environmental conditions (Abolghasemi et al. 2021).

Environmental factors, including temperature, photoperiod, and light quality, have been identified as crucial elements in the regulation of bolting. In contrast, stress factors such as water scarcity or nutrient deficiencies have been observed to enhance bolting tendency in plants. (Cho et al., 2017; Beharav & Hellier, 2020). The regulation of bolting in spinach involves multiple molecular pathways, each consisting of a distinct set of genes with specialized functions (Boss et al. 2004). In this context, the integration of spinach into the cultivation process constitutes a multifaceted undertaking, exerting an influence on the inherent trajectory of plant development. This process is influenced by a confluence of environmental and genetic factors. A thorough evaluation of the mechanisms underlying these factors is imperative. Consequently, the factors that precipitate bolting will be addressed under the headings of genetic and environmental factors.

GENETIC FACTORS AFFECTING BOLTING MECHANISMS IN SPINACH

In species such as radish, carrot, lettuce, and spinach, there is strong argument that the bolting mechanism is controlled by two important integrators; the first is the flower-inducing integrator, which is known as the “FLOWERING LOCUS T (*FT*)” and the second is flower-inducing integrator, which is known as the “CONSTANS (*CO*)”. Based on Kyoto Encyclopedia of Genes and Genomes, spinach holds these two key integrator in the circadian rhythm pathway. This also sheds light on the role of the perception of daily light duration in spinach in flowering. Therefore, photoperiod, vernalization, maturation, internal hormones, and environmental stimuli trigger early flowering or bolting by signaling along circadian rhythm pathway (Abolghasemi et al., 2021). The plant generally undergoes the flowering process via circadian rhythm pathway depending on the duration of light exposure when there are no environmental stress factors. On the other hand, changes in the length of daylight and exposure to different temperatures (especially high temperature) alter the internal hormonal balance, causing bolting in spinach. Changes in the duration of light exposure during the day affect flowering as follows:

The following proteins influence the control of flowering depending on long or short day conditions; FLAVIN-BINDING, KELCH REPEAT, F-BOX 1 (FKF1), GIGANTEA (GI), CONSTANS (*CO*), FLOWERING LOCUS T (*FT*), EARLY FLOWERING 4 (ELF4), CYCLING DOF FACTOR (CDF), SUPPRESSOR OF OVER-EXPRESSION OF CONSTANS 1 cryptochrome (CRY2) phytochrome A (PHYA) and phytochrome B (PHYB). In the early morning hours, *CO* and *FT* promoter regions interacts with CDF factor. In the afternoon of a long day (not in a short day), the FKF1 protein activated by blue light forms a complex with the GI protein. FKF1-GI protein complex increases *CO* transcription by

degrading the that CDF factor in the CO promoter region. By interacting with ELF4-GI, GI displaces from subnuclear compartmentalization in the nucleus during the day-night period and GI complex tends to bind CO promoter region resulting increased CO transcription (Amini et al., 2025; Kim et al., 2013). The accumulated CONSTANS-like proteins binds to the promoter region of the *FT* and *SOC1* integrators together with other transcription factors, thereby increasing transcription in long day candition (Campos-Rivero et al., 2017; Fatima et al., 2024). CO-protein stabilization also plays a role in controlling flowering after post-translational regulation. In post-translational regulation, the far led light-activated PHYA and blue light-activated FKF1 proteins stabilize the CO protein. Also, the CRY2 protein stabilizes CO by suppressing proteins that reduce CO stabilization (Figure 1 and 2) (Abolghasemi et al., 2021; Song et al., 2013). There are numerous findings indicating that the *LNK1* and *LNK2* genes play a critical role in controlling flowering via circadian rhythm pathway (De Leone et al., 2019). The proteins belonging to *LNK* family are not effective in controlling flowering alone, but interact with certain MYB-type transcription factors (in such case; LHY and circadian clock associated) to control the plant's circadian rhythms, photomorphogenic reaction, and photoperiod-dependent flowering. Due to the the lack of DNA binding domain of *LNK* type protein, *LNK1* and *LNK2* protein form morning complex with REVEILLE/LHY-CCA1-LIKE (RVE/LCL) REV4/REV8 like transcription factor for increasing transcription rate of *TOC1* and *PRR5* (Ma et al., 2018). It is stated that *TOC1* and *PRR5* coordinately regulate *CDF1* expression in a negative direction (Amini et al., 2025; Ito et al., 2008; Liu et al., 2021). In this case, it promotes the synthesis of the CO protein essential for flowering, and flowering occurs evetually. Changes in the photoperiod, which is one of the critical stimulants of the flowering mechanism, cause shifts in the circadian rhythm pathway in species such as spinach, and trigger early flowering/bolting (Chun et al., 2001; Hata et al., 2006; Vajjiravel et al., 2024).

Figure 1. Protein-protein interaction of bolting related spinach proteins.

Figure 2. Gene Ontology enrichment of bolting related spinach proteins

Another important factor triggering bolting is complex relation between photoperiodic pathway and gibberellic acid hormone metabolism. The increase in ambient temperature also promotes bolting through gibberellic acid metabolism. The precondition for bolting is the stem elongation of the plant and its transition from the vegetative phase to the generative phase. Many researchers agree on gibberellic acid (GA) synthesis being responsible for stem elongation, cell division, and bolting (Binenbaum et al., 2018; Xie & Chen, 2020; Zeevaart et al., 1993). It has been demonstrated that there is a significant increase in the ratio of proteins belonging to the *GA20ox1* gene in spinach under long-day photoperiodic conditions (Lee & Zeevaart, 2007). *GA3ox* and *GA20ox1* genes are two important genes involved in gibberellic acid synthesis, and their high levels of transcription have triggered bolting in some species (García-Martínez & Gil, 2001). The light-activated product of the *PHYB* gene negatively regulates the *PHYTOCHROME-INTERACTING FACTOR 3-LIKE 5 (PIL5)* transcription factor (Ghorbani et al., 2021). Decreased *PIL5* levels lead the active functioning of the *GA3ox* gene and cause ultimately the production of active GA. In shoot apex part, *PHYB* dependent GA biosynthesis is increased in model plant *Arabidopsis* (Hisamatsu & King, 2008). Moreover, there are many studies indicating that *FT* expression independently increases GA synthesis under long-day conditions (Bao et al., 2019). Thus, GA production increases both through light activation (*PHYB*, *PIL5*) and independently *FT* locus expression ((Bao et al., 2020). Two transcription factors, *TEMPRANILLO 1 (TEM1)* and 2, which suppress the *FT* locus, also suppress the expression of the *GA3ox1,2* genes (Osnato et al., 2012). It also lowers the GA level in the plant. On the other hand, when there is sufficient light for a longer period of time, the effect of *TEM* genes, that suppress the *FT* locus and the *GA3ox1,2* genes, disappears, and the *FT* locus activates *AP1* via *SOC1* resulting GA synthesis/accumulation. In the presence of GA, *FT* and *SOC1* cause flowering of plants (Osnato et al., 2012; Srikanth & Schmid, 2011). Consequently, GA production triggered by day length or exogenous GA applications causes the plant to elongate first and then promote flowering through the circadian rhythm.

The final external stimulus that initiates bolting is high temperature stress. The effect of heat stress on flowering occurs via the autonomous pathway. It has been determined that the *FCA* and *FVE* genes located on the autonomous pathway are among the genes that function as thermosensors (Blázquez et al., 2003). It has been demonstrated that there is an increase in *FCA* expression with increasing temperature (Xu et al., 2025). *SVP* protein negatively regulates flowering integrator *FT* and *SOC1* locus. The increased *FCA*, *FVE* and *FLM-δ* activity at high temperatures compete *SVP* proteins, which prevent the binding of promoters necessary for flowering (Capovilla et al., 2014). The proteins and nucleic acids that perform this thermal sensing vary depending on the plant family (Zhu et al., 2025). The transcription of integrators that promote flowering begins with the detachment of *SVP* protein from the promoter region of these integrators. In addition, many studies have found evidence that *PHYTOCHROME INTERACTING FACTOR4 (PIF4)* directly activates the *FT* locus (Kumar et al., 2012). Besides this mechanism, *mir156* another regulation mechanism that targets the *SQUAMOSA PROMOTER BINDING PROTEIN-LIKE (SPL)* genes directly and *SPL* increases the expression of the *FT* and *SOC1* loci (Amini et al., 2025; Avşar & Esmaeili Aliabadi, 2017; Huijser & Schmid, 2011). In relation to all of this, the genetic mechanism that triggers bolting, especially in spinach, generally manifests itself through the circadian rhythm pathway. Light, high temperature, and endogenous/exogenous increased GA levels stimulate different sections of the circadian rhythm pathway, thereby affecting bolting in spinach. This situation has been observed in protein-protein interactions and gene ontology enrichment (Figure 1 and 2). It was created specifically for protein-protein interactions analysis by including proteins derived from various studies conducted on bolting in spinach.

4. MECHANISMS OF ENVIRONMENTAL FACTORS AFFECTING BOLTING

The nutritional and marketing value of vegetables is greatly affected by bolting. The economic value of spinach is significantly influenced by its yield performance, which is greatly affected by environmental factors such as light, temperature, water, humidity, and nutrition (van Treuren et al., 2017). The transition phase between vegetative growth and reproductive growth in the plant begins with bolting (stem elongation) (Mutasa-Göttgens et al., 2010). This is considered a critical event due to the coordinated effects of various environmental factors and developmental components (Melchinger, 1998; Chen et al., 2019), and is known to be one of the most important factors causing significant declines in quality, productivity, and serious economic losses in spring spinach production (Abe et al., 2014; Ma et al., 2016).

Spinach is easily influenced by photoperiod (Chun et al., 2000) and bolts in spring (Tang et al., 2018). New slow-bolting spinach varieties that can adapt to a wide range of photoperiods and climatic conditions are available (Bhattarai and Shi, 2021). Selecting appropriate varieties will increase breeding and production efficiency in spinach (Goreta and Leskovar, 2006).

Bolting and Flowering Factors

Vernalization, which is necessary for the formation of flower organs and the regulation of flowering, is the passage of the plant from the vegetative growth stage to the reproductive stage through a period of continuous low temperatures (Zhu, 2023).

Prerequisites for bolting include seed vernalization (Filek et al., 2010), plumule vernalization (Dai et al., 2023), devernalization (Yu et al., 2010), and vernalization (Akter et al., 2021). Amaranthaceae plants, including spinach, and *Brassicaceae* plants such as radish, Chinese cabbage, choy sum (*B. campestris* L. ssp. *chinensis* var. *utilis* Tsen et Lee), turnip, and mustard primarily undergo seed vernalization.

Bolting and Flowering Pathways

Changes in environmental conditions such as vernalization temperature and light can cause immature bolting in many vegetable crops, which reduces yield and commercial value (Ma and Dai, 2019; Moe et al., 1985). Many important bolting and flowering genes have been identified and functionally characterized in *Arabidopsis*. *Arabidopsis* is characterized by flowering axis elongation-type bolting (Chen et al., 2019), which provides a reference for studying bolting and flowering genes in spinach. Genetic studies in *Arabidopsis* have revealed that genes controlling bolting and flowering are involved in and can be assigned to different regulatory pathways, including photoperiod, vernalization, gibberellin, autonomous, environmental temperature, and age (Fornara et al., 2010). These pathways are related to plant development and environmental cues such as photoperiod and temperature (Cho et al., 2017).

Vernalization and Devernalization Pathway

Photoperiod pathway: In long-day plants such as spinach, early flowering can be triggered by long light periods. The length of this light period is particularly beneficial for flowering in plants such as spinach and garlic (Tan et al., 2024).

Gibberellin (GA) pathway: GA plays an important role in regulating flowering. In plants like lettuce, exogenous GA3 and low-temperature treatments significantly increase GA levels, leading to early flowering and flowering (Wang et al., 2022).

5. BOLTING MANAGEMENT

The effective management of bolting is of great importance to maintain both yield and product quality. To this end, agronomic and genetic strategies are evaluated in concert. Such strategies include, but are not limited to, appropriate planting time, temperature control, optimization of environmental conditions, minimization of stress factors, and variety selection. This approach is noteworthy as a successful management strategy within the production process. In this section, the subject of measures that can be taken for bolting management is addressed.

Optimum Planting Time

Bolting is a salient trait that must be considered in the context of cultivating spinach for year-round production, given its sensitivity to photoperiod (Chun et al. 2000). Exposure to prolonged daylight hours has been demonstrated to induce bolting in spinach, rendering the plant unmarketable (Goreta and Leskovar, 2006). Given that some commercially cultivated spinach is harvested multiple times, overwintered spinach, which is prone to spring bolting, can diminish the number of harvests that can be obtained, consequently reducing the total yield (Morelock and Correll, 2008). Chun et al. (2000) discovered that the process of bolting can be influenced by alterations in light conditions during the sowing stage. However, this method is not feasible for large-scale production due to the predominant practice of direct seeding in spinach cultivation (Koike et al. 2011). Indeed, bolting, defined as rapid stem elongation that eventually leads to flowering, can occur at any time of the year. However, spinach sown in spring or summer is more markedly prone to bolting. In this context, it has been reported that bolting can be prevented by controlling environmental conditions in the growth chamber, using spinach varieties with low photoperiod sensitivity, or planting 50-60 days before the onset of long summer days (Chitwood et al. 2016). Consequently, it is imperative to acknowledge that fall and early spring sowing should be conducted in temperate climate regions where spinach is cultivated, while summer sowing should be avoided.

Selection of Late Bolting Varieties

In the context of spinach cultivation, agronomic traits such as plant height, leaf erectness, and stem emergence are of significant importance. Favorable photoperiod insensitivity is a desirable characteristic for year-round production, and thus, the late or slow emergence of these traits is preferred (Chun et al. 2000). It has been demonstrated that slow or late emergence is a desirable trait in commercially cultivated spinach. This species is typically harvested multiple times during the growing season, thereby increasing the overall yield. Commercial spinach cultivation is highly mechanized (Morelock and Correll, 2008; Koike et al., 2011), and to adapt to high-density spinach production and mechanical harvesting, growers generally prefer spinach varieties with taller plant height and upright leaves. In this context, studies conducted over many years on the detection of genetic variation in spinach have revealed that there is a level of variation within the species that can be evaluated in terms of late emergence trait, suggesting that it may be possible to develop late emerging varieties through breeding programs (Goreta and Leskovar, 2006). In a study that classified bolting as early, medium, or late based on phenotypic data in spinach, it was reported that eight cultivars with late bolting, erect leaves, and a plant height of 9 cm (PI103063, PI169678, PI169684, PI171863, PI171865, PI174386, PI175929, and PI648963) could be used as parents in a spinach breeding program (Chitwood et al. 2016). In this regard, the late bolting of plants has been

identified as a primary focus of economic production and scientific research (Chitwood et al. 2016; Abolghasemi et al. 2021). Research has indicated that varieties such as 'Matador', 'Bloomsdale Long Standing', and 'Tyee' exhibit enhanced resistance to bolting (Kaşka, 2020).

Temperature and Light Control

Researchers have generally reported that the primary factors contributing to bolting are associated with day length and elevated temperatures (Shi et al., 2016). Ambient temperature is one of the factors that affect growth, development, and flowering time throughout the plant's life cycle. Research has demonstrated that the majority of plants exhibit early flowering in response to elevated temperatures (Jagadish et al., 2016). It has also been reported that many plant species have the ability to initiate flowering at the optimal time for their reproduction, which mainly depends on accurate measurement of seasonal changes in day length and temperature (Hayama et al. 2003; Shi et al. 2016). Photoperiod sensitivity is therefore a critical factor in measuring critical day length and determining flowering time in plants. A modification in this factor has been demonstrated to induce alterations in flowering time and can enhance adaptation to local environmental conditions in numerous plant species (Jung and Muller, 2009). In spinach, the optimal growth temperature range is between 10-20°C, while temperatures above 24°C can trigger bolting.

Fertilization

Excessive or deficient levels of certain elements in the soil have been demonstrated to alter flowering time (Bernier et al., 1993; Wada and Takeno, 2010). In general, malnutrition has been demonstrated to promote flowering. *Pharbitis nil*, a short-day plant, has been observed to induce flowering when cultivated under long-day conditions and when nutrients were scarce, but not when plants were supplied with standard nutrient solutions (Shinozaki et al., 1988; Wada and Takeno, 2010). These results suggest that the mechanism of induction due to nutrient deficiency is different between short and long day conditions. The induction of flowering is more pronounced under short-day conditions, and this effect is more significant in younger plants.

Nitrogen is one of the macrolelements required by plants that regulate a wide range of biological processes (Vidal et al. 2014). In *Arabidopsis*, nitrate-limiting conditions have been reported to promote flowering under neutral or short-day conditions, and this response is independent of vernalization and autonomous pathways (Marín et al. 2011; Liu et al. 2013). However, when nitrate was limited, transcript levels of gibberalic acid biosynthesis genes and GA3 concentrations were reported to increase (Liu et al. 2013). Few studies have focused on how other nutrients alter this timing. In alpine *Gnaphalium supinum*, flowering was increased due to a greater supply of phosphorus, while nitrogen was reported to have no effect (Petraglia et al. 2014). In *Arabidopsis*, flowering was delayed under low phosphorus conditions, while flowering was reported to be unchanged when high phosphorus was applied to plants (Kant et al. 2011). In this context, while elements such as phosphorus support root development and general plant health, excessive nitrogen fertilization can also trigger bolting by promoting rapid growth in the plant. Therefore, it should be kept in mind that balanced fertilization is important in cultivation.

ABSTRACT

In this study, a single female mite specimen belonging to the genus *Eupalopsellus*, collected from Türkiye, was examined morphologically in detail. The specimen displays key morphological affinities with *Eupalopsellus kermaniensis* Mahdavi & Farzan, particularly in dorsal shield ornamentation and leg chaetotaxy. However, it also possesses several distinguishing features, such as markedly shorter dorsal body setae and notably longer setae *ag*₂ and *ag*₃. A pair of wing-like sclerotized structures adjacent to the anogenital shields, also present in *E. kermaniensis*, was observed in the examined specimen. Similar wing-like structures have been found in *E. oresbiosis* Smith Meyer & Ueckermann and *E. sellnicki* Smith Meyer & Ueckermann, indicating a degree of morphological resemblance to these species as well. Nevertheless, the absence of solenidion ω on tarsus IV of the specimen differentiates it from these taxa. The combination of these morphological characters, while closely resembling *Eupalopsellus* aff. *kermaniensis*, suggests that it may represent an as yet undescribed species of *Eupalopsellus*; however, further material is required to confirm this.

Keywords: Mite, taxonomy, diagnostic morphology, new species candidate

INTRODUCTION

Eupalopsellidae Willmann is a family belonging to the superfamily Raphignathoidea. Members of this family are active predators and they act as biocontrol agents of small arthropods (Fan, 2004; Khan et al., 2024). At present, Eupalopsellidae includes about 50 described species in five valid genera (Gerson and Walter, 1998; Beron, 2020; Khan et al., 2024). *Paraeupalopsellus* Smiley & Moser and *Acaciacarus* Gerson, Frost & Swift (syn. of *Mecognatha* Wood) are now members of the family Mecognathidae Gerson & Walter in the current classification (Gerson and Walter, 1998).

Currently, twenty species belonging to the genus *Eupalopsellus* Sellnick are known in the world (Beron, 2020; Khan et al., 2024), four of which have also been recorded in Türkiye: *E. olandicus* Sellnick, *E. rostridius* Summers, *E. prasadi* Bagheri & Khanjani and *E. deformatus* Fan (Doğan and Ayyıldız, 2004; Dönel and Doğan, 2010; Kasap et al., 2013; Doğan et al., 2017, Doğan, 2019).

In this study, a female specimen of the genus *Eupalopsellus* collected from Karasu Valley was herein described and photographed. Morphological comparisons with the related species in the genus revealed that, although the specimen exhibits certain characteristics similar to those of the related species, it also displays distinct differences in other observed morphological traits. The subject of this work is whether this specimen constitutes a new species, a question which was addressed by comparing it with other related species.

MATERIALS AND METHODS

The mite specimen was extracted using Berlese-Tullgren funnels, cleared in 60% lactic acid and mounted on microscopic slides in Hoyer's medium under a stereo microscope. Photographs were taken using a Leica DM 4000B phase-contrast light microscope. Body size and measurements of various structures of the body were taken in micrometers (μm) with the aid of the Leica Application Suite (LAS) Software Version 3.8. The terminology is based on Kethley (1990) and Grandjean (1944, 1946). Specimen examined was deposited in Acarology Laboratory of Erzincan Binali Yıldırım University (EBYU), Erzincan, Türkiye.

RESULTS

Family: Eupalopsellidae Willmann

Genus: *Eupalopsellus* Sellnick

***Eupalopsellus* aff. *kermaniensis* Mahdavi & Farzan**

Description

Female

Idiosoma oval. Length of body 298, width 191. Dorsum of idiosoma covered with four shields. Integument striated and punctuated except for shields. All dorsal shields punctuated. Length of propodosomal shield 73, width 99. Propodosomal shield with four pairs of setae (*vi*, *ve*, *sci*, *sce*), a pair of eyes and a pair post-ocular bodies; eyes 10, post-ocular bodies 20 in diameter. Length of metapodosomal shield 73, width 119. Setae *c*₁, *d*₁, *d*₂ located on metapodosomal shield. Setae *c*₂ located on striated integument, humeral shields absent. Length of opisthosomal shield 80, width 108, with three pairs of setae (*e*₁, *e*₂, *f*₁). Length of suranal shield 40, width 91, bearing two pairs of setae (*h*_{1,2}). Dorsal idiosomal setae faintly barbed; the barbs on the setae *f*₁, *h*₁, *h*₂ more prominent compared to the others. Lengths and distances of dorsal body setae as follows; *vi* 11, *ve* 12, *sci* 13, *sce* 15, *c*₁ 13, *c*₂ 20, *d*₁ 14, *d*₂ 15, *e*₁ 15, *e*₂ 15, *f*₁ 35, *h*₁ 31, *h*₂ 31, *vi-vi* 24, *ve-ve* 54, *vi-ve* 20, *sci-sci* 10, *sce-sce* 84, *sci-sce* 38, *ve-sce* 27, *vi-sci* 51, *ve-sci* 44, *c*_{1-c}₁ 82, *c*_{2-c}₂ 137, *d*_{1-d}₁ 79, *c*_{1-d}₁ 59, *d*_{2-d}₂ 107, *c*_{1-d}₂ 51, *d*_{1-d}₂ 17, *e*_{1-e}₁ 66, *e*_{2-e}₂ 96, *e*_{1-e}₂ 28, *f*_{1-f}₁ 72, *e*_{1-f}₁ 25, *e*_{2-f}₁ 49, *h*_{1-h}₁ 43, *h*_{2-h}₂ 79, *h*_{1-h}₂ 18.

Figure 1. *Eupalopsellus* aff. *kermaniensis* (female). A) Dorsum of body, B) Venter of body.

Figure 2. *Eupalopsellus* aff. *kermaniensis* (female). A) Elongated rostrum of subcapitulum and right palp, B) Anogenital region.

Coxisternal shields absent. Setae 1a situated between coxae I, setae 3a located between and anterior to coxae III and setae 4a on striated integument and located between coxae IV. Three pairs of aggenital setae (ag_{1-3}) present. A pair of wing-shaped sclerotized structures located below setae ag_3 . A pair of genital setae (g_1) and three pairs of pseudanal setae (ps_{1-3}) present. Lengths and distances of the setae as follows; 1a 53, 3a 69, 4a 35, 1a–1a 25, 3a–3a 40, 4a–4a 28, ag_1 13, ag_2 25, ag_3 35, g_1 27, ps_1 21, ps_2 22, ps_3 18.

Lengths of legs; I: 198, II: 170, III: 168, IV: 174. Setal formulae of legs I–IV; coxae 2–1–2–2, trochanters 1–1–1–1 femora 4–4–3–1, genua 1(+1κ)–1–1–1, tibiae 5(+1φρ)–4(+1φρ)–4(+1φρ)–4(+1φρ), tarsi 10(+1ω)–9(+1ω)–6(+1ω)–6.

Gnathosoma 143, chelicerae 141 long. Palp tarsus 37, palp tibia 18 long and total length of palp 143. Number of setae on palp segments from palp trochanter to palp tarsus: 0-3-1-3-4/5?+1ω+1 terminal eupathidium. Tibial claw minute, and seta-like. Lengths and distance between subcapitular setae, m 32, n 50, $m-m$ 8, $n-n$ 15, $m-n$ 30.

Material examined

1 ♀, from litter, 39°36'47.19"N 38°40'0.04"E, 1711 m a.s.l, the Karasu Valley, Türkiye, 27 September 2022.

DISCUSSION

In the examined specimen, a pair of wing-shaped sclerotized structures were observed just below the setae ag_3 (Figs 1B, 2B). In addition to this characteristic, the specimen closely resembles *Eupalopsellus kermaniensis* Mahdavi & Farzan in terms of leg setations and other morphological features (Mahdavi et al., 2013). However, the Turkish specimen differs in that the dorsal integument is striated and punctuated, the dorsal setae are significantly shorter compared to those of *E. kermaniensis*, and setae ag_2 and ag_3 are much longer (Figs 1A, 2B).

A pair of wing-shaped structures located on the sides of the anogenital shields are also present in *Eupalopsellus oresbiosis* Smith Meyer & Ueckermann and *E. sellnicki* Smith Meyer & Ueckermann (Smith Meyer & Ueckermann, 1984). Therefore, the Turkish specimen may also be closely related to these species. However, it can be easily distinguished from them by the absence of the solenidion ω on tarsus IV. In the mentioned species, solenidion ω is present on tarsus IV.

The combination of all these morphological characters indicates that the examined specimen is most closely related to *Eupalopsellus kermaniensis* among the previously mentioned species. So far, only a single specimen has been found, and no additional specimens of the same species have been encountered.

CONCLUSION

The findings indicate that the examined specimen can be identified as *Eupalopsellus* aff. *kermaniensis*, but it may represent a potential new species due to its morphological differences from the known species. However, to confirm this assumption and to make a description species-level identification, additional specimens from the same population or from similar habitats are required. Accordingly, detailed future sampling efforts and comparative morphological analyses will contribute significantly to clarifying the taxonomic status of this potential new species.

ACKNOWLEDGEMENT

ABSTRACT

The purpose of this study was to determine and to map soil pH and macronutrient content in soils located in Ordu province. For that purpose, soil samples were collected from the study area to evaluate the soil fertility. The soil samples were analyzed to determine soil pH and total N, available P and available K, Ca, Mg. Then, soil nutrient maps were prepared by IDW method with this obtained data results. In the present study, the pH of the soils was between 4.91-6.25 indicating moderately acid to slightly acid. Maps of the soil macronutrients showed that total N content in soils was at sufficient level in the entire study site; available P, Ca and Mg content were found at the low and high level in the soils and available K content of the soils were at high level. In addition to, soil nutrients were significantly positively correlated with each other.

Maps showed that soil nutrients were at the high level in the study site. Soil nutrient maps indicated that macronutrients in soils were found at different levels in the study site and nutrient level was differ widely in the map. Soil nutrient maps revealed that study site should be managed differently according to the nutrient and it is important.

Keywords: Macronutrient, pH, acid soil, interpolation, GIS

INTRODUCTION

Soil nutrient mapping has a great importance as it provides essential information about the soil properties that affects plant growth (Tudi, 2022). Soil macronutrients includes nitrogen, phosphorus and potassium. Total nitrogen, available phosphorus and available potassium are basic parameters of soil fertility among soil nutrients. Mapping of the spatial distribution of soil macronutrient such as total nitrogen and available phosphorus, available potassium through mapping techniques is significant for agricultural management.

GIS methods have been widely used in soil science to detect spatial variability of nutrients in soils (Tiruneh et. al 2021). GIS application provides methods for identify the spatial distribution of soil properties and helps create a mapping model. Mapping of pH of the soil and nutrients are of considerable importance in hazelnut for nutrient management. It is essential to generate the maps of nutrients in soils in order to plan site specific fertilizer programme.

The purpose of this research was to determine soil pH and macronutrient content in soils of Hazelnut, located in Ordu and to generate a map of soil nutrients the areas that need a fertilization based on soil nutrient level for hazelnut.

MATERIAL AND METHODS

Study area

The study site is 12.5 da hazelnut orchards, located in Ordu province. It is situated at the longitude 402520-402685 East and latitude 4524840-4525015 North (WGS84 UTM Zone 37 North).

Figure 1. Location of study area and sampling point

Soil sampling and analysis

Twenty-five soil samples were collected at a depth 0–30 cm, in April 2025. The soil samples were taken randomly in study site (Fig. 1) and the sampling positions were geo-referenced and recorded using a GPS. This random soil sampling was taken before the application of fertilizer. This random sampling was taken prior to the soil fertilization.

The soil samples were dried in the shade and passed through a 2 mm sieve and analysed for soil pH, total N, available P, available Ca, available K, available Mg. Soil pH was detected using a pH meter at a 1:2.5 soil:water ratio (w:v) (Richards, 1954). Total N was determined by Kjeldahl method (Bremner 1965). Available P was determined by Bray Kurtz method through spectrophotometry (Kacar, 2009). Available Ca, Mg and K were extracted with neutral normal ammonium acetate solution ($\text{NH}_4\text{OAc-K}$) and were determined on an AAS (Kacar, 2009).

Mapping model

Maps of spatial distribution of soil pH and macronutrients were prepared in Arc GIS 10.5 software using the inverse distance weighted (IDW) interpolation method (Tiruneh et. al. 2021).

Statistical Analysis

Descriptive statistic of soil data (min, max., mean, standard deviation, coefficient of variation, skewness and kurtosis) were performed using Minitab 20. Pearson correlation was used to investigate relationships between soil pH and macronutrient. Significant differences were determined by Pearson least significant difference (LSD) test ($p < 0.05$).

RESULTS AND DISCUSSION

Descriptive statistics of soil fertility parameters

Descriptive statistic of soil data such as minimum, maximum, mean, standard deviation, coefficient of variation (CV), skewness and kurtosis are presented in Table 1. The soil fertility parameters were selected as soil pH and macronutrients; total N, available P, K, Ca and Mg. The coefficient of variation was calculated to investigate the variability of soil fertility parameters using the following order ≤ 25 low variations; $25 < CV \leq 50$ moderate variations and > 50 high variations (Khadka et al. 2018). The results showed that the highest variability in coefficients of variation was in soil phosphorus while lowest variability in soil pH. In addition to this, CV was moderate variation for other soil macronutrients.

Table 1. Descriptive statistics of the soil fertility parameters in the study area

Properties	Mean	StDev	CV	Min	Max	Skewness	Kurtosis
pH	5.51	0.33	6.13	4.91	6.25	0.37	-0.01
N, %	0.193	0.051	26.4	0.13	0.35	1.48	2.47
P, mg kg ⁻¹	18.30	18.64	101.8	0.01	60.75	0.91	0.03
K, mg kg ⁻¹	475.7	208.4	43.8	204.4	1077	1.18	1.56
Ca, mg kg ⁻¹	1143	544	47.5	419	2645	1.06	1.08
Mg, mg kg ⁻¹	181.8	60.4	33.2	98.2	286.3	0.31	-1.30

Pearson correlation relations

Pearson correlation coefficients between data of soil fertility parameters are presented in Table 2. The soil macronutrients were positively correlated with each other in this study. Significant relationship was found between soil pH and available P ($r = 0.595$, $p < 0.01$); available K ($r = 0.404$, $p < 0.01$). In this study, there was no significant relationship between soil pH and total N, available Ca, available Mg. In addition to this, positive relationship was found between soil available Ca and Mg ($p < 0.01$); soil available P and soil available K ($p < 0.05$); soil available K and Mg ($p < 0.05$).

Table 2. Correlation relation between soil pH and macronutrient

	pH	N	P	K	Ca
N	-0.083				
P	0.595**	0.009			
K	0.404*	0.435*	0.487*		
Ca	0.073	0.258	0.181	0.221	
Mg	0.166	0.380	0.216	0.443*	0.840**

Classification of limit values for soil parameters

The classification of the limit values for soil pH and macronutrients are presented in Table 3. These limit values of the soil parameter were used for preparing soil maps.

Table 3. Classification of limit values for soil parameters

Parameter	Interpretation Classes					References
	Very low	Low	Adequate	High	Very high	
N %	<0.045	0.045-0.090	0.090-0.170	0.170-0.320	>0.320	Sillanpää, 1990
P, mg kg ⁻¹	<2.5	2.5-8.0	8.0-25	25-80	>80	Sillanpää, 1990
K, mg kg ⁻¹	<50	50-110	110-290	290-1000	>1000	Sillanpää, 1990
Ca, mg kg ⁻¹	<238	238-1150	1150-3500	3500-10000	>10000	Sillanpää, 1990
Mg, mg kg ⁻¹	<50	50-160	160-480	480-1500	>1500	Sillanpää, 1990
pH	Strongly acidic	Moderately acidic	Slightly acidic	Neutral	Slightly Alkaline	Richards, 1954
	<4.5	4.5-5.5	5.5-6.5	6.5-7.5	7.5-8.5	

Map of soil pH and macronutrients

The maps of the soil pH and macronutrients are presented in Figure 2 and Figure 3. The soil pH of the study site varied from 4.91 to 6.25, indicating moderately acidic to slightly acidic. In addition to this, the map of soil pH showed that soils were more acidic in the west of the study area (Fig. 2).

Figure 2. Map of soil pH and total nitrogen

The total nitrogen content of the soils was between 0.13 and 0.35 % with the mean of 0.19 %. (Table 1). The total nitrogen content was found at both adequate and high level in the study site. The map showed that most of study area was high level in total nitrogen content. (Fig. 2). In this study, available P contents of the soils varied from 0.01 to 60.75 mg kg⁻¹ with the mean of 18.30 mg kg⁻¹ (Table 1). This indicates that the available phosphorus contents in soils varied from very low to high level. The map in Fig. 3 showed that available P content in the soils was higher in the south eastern of the study site.

The map indicated that south part of the study area was insufficient in available phosphorus content (Figure 3). The available K content in the soils was between 204.4 and 1077 mg kg⁻¹ with the mean of 475.7 mg kg⁻¹. The available potassium values were found at adequate, high and very high level in the soils. The map of soil available potassium showed that available K content was sufficient level in total study area. (Figure 3). Thus, available K content in the soils was high level in the study site.

Figure 3. Map of soil available P, K, Ca and Mg

The available Ca content in the soils was between 419 mg kg⁻¹ and 2645 mg kg⁻¹ with the mean of 1143 mg kg⁻¹ (Table 1). This map shows that available Ca in the soils was found at both low and adequate level (Fig. 3). In addition to, soil map shows that available Ca content in the soils was more present in south of the study site.

In this study, available Mg content ranged from 98.2 to 286.3 mg kg⁻¹ with the mean of 181.8 mg kg⁻¹ in soil. The map indicated that available magnesium contents in the soils were low and adequate level (Fig 3). The map showed that available Mg content in the soils was more present in the south of the study site. The majority of the study area was adequate in magnesium content and remaining area was low in magnesium content.

CONCLUSION

In this study, pH of the soils was generally slightly acidic and soil nutrients were found at different level. The spatial distributions map of the soil Ca and Mg showed both nutrients were adequate level in the south of the study site. However, soil available Ca and Mg contents were deficient in the majority of the study site. In addition to this, spatial distributions map of the soil available P indicated that soil P was deficient in the south western of the study site. There were differences in the amount of nutrients in the soils of the study site. P, Ca and Mg fertilization should be added to the fertilizer programme to increase nutrient content in the soils of hazelnut. The maps generated for the study may be useful for creating fertilizer programme and to determine the amount and kind of macronutrient to be applied based on the site specific nutrient management.

ABSTRACT

With the advancement of technology in nature-related sciences, solutions in these fields are also shifting towards digitally focused approaches. Among these, fields such as agriculture, forestry, zootechnics, aquaculture, and biomedicine are leading breakthroughs in leveraging the benefits of artificial intelligence and Industry 5.0. Because Industry 5.0 is human-centered, the technology it seeks must be human-friendly and, therefore, close to nature. Therefore, the robot-nature relationship, including artificial intelligence, opens the door to a hybrid world. In this context, artificial intelligence provides us with the key to utilizing these two components. With machine learning and deep learning algorithms, artificial intelligence helps us leverage functions in the created environment and utilize them in the right direction. On the technical side, the correct use of data and algorithms allows us to manage technology effectively and achieve rapid results. This study compiles and discusses the applications of the technical aspects of Industry 5.0 and artificial intelligence used in the aforementioned fields of agriculture, forestry, zootechnics, aquaculture, and biomedicine. The article also discusses the impact of machine learning on modern and traditional methods in these fields. It also touches on assistive technologies such as 6G and IoT. Thus, the aim of this review is to inform and guide scientists on the most appropriate AI application(s) for their field of study.

Keywords: Artificial Intelligence, Bioscience, Machine Learning

INTRODUCTION

According to statistics on the world population, it is predicted that the world population will reach 10 billion by 2050 (Taha et al., 2025). Agriculture, forestry, zootechnics, aquaculture, and biomedicine are pioneering fields that will inevitably be affected by population growth. In this context, the use of technologies developed to make more effective use of nature's resources and to protect the world plays an important role. This role will be fulfilled by Industry 5.0 and artificial intelligence. In addition, interdisciplinary fields will also contribute to the process. Developments in robotics can be an example of this. Ultimately, it is essential for scientists to address these issues and develop innovative and sustainable systems to meet the needs of the growing population.

Machine learning, a subfield of artificial intelligence, has revolutionized resource management and decision-making by analyzing data and creating accurate prediction models. This technology facilitates informed and data-driven decision-making by enabling the identification and analysis of complex patterns in data from various sources using sensors and other equipment. Artificial intelligence applications, machine learning technologies, and applications working with the Internet of Things have shown remarkable growth in recent years.

The occurrence of several outbreaks and pandemics has further increased the global importance of these technologies (Ramachandran et al., 2022). Machine learning refers to the artificial intelligence method that enables computers to accomplish specified types of tasks and problem-solve issues without direct processing. This method enables a mechanism to be designed that can effectively execute a specific task by training a machine or computer on data related to that issue or mission (Bensoussan et al., 2020). Advances in computational capability and big data technologies are facilitating the evolution of deep learning, a highly sophisticated and practical form of machine learning. Deep learning has revolutionized fields such as object sensing, identification of powdered foods, crop nutrition sensing, leaf area metering, disease recognition, moisture stressed crops, plant health monitoring, fruit quality assessment, and other complex tasks involving large-scale data analysis (Fan, 2022). The performance of computer systems in these applications has reached extraordinary levels, enabling them to completely replace human intervention in certain operations or significantly support it. These technologies have permeated various sectors, including agriculture, where artificial intelligence, machine learning, deep learning, the Internet of Things (IoT), and other digital technologies are widely adopted, leading to the emergence of the concept of “smart agriculture” and the goal of achieving fifth-generation agriculture (Agriculture 5.0 (Ag5.0)) (Doshi & Varghese, 2022).

Agriculture 5.0 is an innovative, evolving version of agriculture that aims to address issues not covered by Agriculture 4.0. Agriculture 5.0 is a subcategory of Industry 5.0, a new concept that needs to be adopted, which involves integrating new technologies such as artificial intelligence, the Internet of Things (IoT), big data analytics, digital twins, blockchain, 6G networks, robotics, and human-machine interaction to manage various agricultural processes (Mourtzis et al., 2022).

Figure 1 shows the roadmap of the agricultural revolution from Agriculture 1.0 to Agriculture 5.0. The technologies offered in Agriculture 5.0, built upon the progress made from Agriculture 1.0 to Agriculture 4.0, will contribute to addressing some of the current global challenges of producing sufficient, affordable, and healthy food while protecting ecosystems (Taha et al., 2025). However, 6G technology, capable of providing transmission speeds of up to 1 Tbps, will expand IoT connectivity thanks to higher data speeds, minimal latency, and wider coverage. This will improve the management of agricultural resources by enabling advanced AI-based monitoring and precision farming techniques (Maddikunta et al., 2022).

Figure 1. Timeline of the Agricultural Revolution (Taha et al., 2025)

Artificial intelligence, along with its core subfields such as machine learning and deep learning, is an integral part of Agriculture 5.0, and these areas play critical roles. Machine learning is a subclass of artificial intelligence that enables machines to learn automatically from data without the need for explicit programming. Machine learning is of critical importance for Agriculture 5.0 and assists in predicting crop yields, monitoring plant diseases, assessing nutrition and water status, detecting weeds, and forecasting adverse weather conditions such as rainfall, drought, and wind (Sarker, 2021). Deep learning, a subfield of artificial intelligence and machine learning, uses artificial neural networks (ANNs) inspired by human brain functions for complex computations. Deep learning methods such as convolutional neural networks (CNNs), recurrent neural networks (RNNs), autoencoders, and generative adversarial networks (GANs) are applied to specific agricultural challenges (Hong et al., 2020).

Plants are important components of ecosystems; they facilitate carbon exchange and provide food and habitat for both animals and humans. In terms of diversity and population, forest plants are at risk of extinction due to overuse and poor management (Fichtner & Härdtle, 2021).

Sustainable forest management refers to the conservative balancing of ecological, social, and economic objectives to ensure the permanence and resilience of natural ecosystems, particularly forest plants, while also enabling their utilization. The emergence of artificial intelligence is modernizing sustainable forest management by offering innovative solutions for monitoring, modeling, decision-making, and law enforcement (Fallah Madvari, 2022).

Forests are vital components of the environment and must be protected. For centuries, their management and protection have relied on traditional methods. However, the emergence of artificial intelligence, machine learning, and deep learning has transformed forest management (Shivaprakash et al., 2022).

Artificial intelligence primarily automates and enhances the analysis of complex datasets obtained from digital technologies such as satellites, drones, and aerial imagery, mimicking human intelligence. Artificial intelligence processes and interprets large amounts of data, thereby reducing dependence on manual labor (Buchelt et al., 2024).

Machine Learning, a subfield of artificial intelligence, works on algorithms that offer innovative solutions to compact environmental challenges through the efficient and accurate analysis of large amounts of data. Machine Learning facilitates better decision-making and precise forest resource management. Deep Learning, another subfield of Machine Learning, helps optimize forest resources more effectively by using techniques that are becoming increasingly important in sustainable forest management. Deep Learning systems utilize large-scale, high-dimensional data obtained from satellites, environmental sensors, and other components (Diez et al., 2021; Raihan, 2023).

Artificial intelligence is increasingly being incorporated into sustainable forest management to overcome challenges related to protection, resource management, and plant protection. This has enabled forest management and enhanced sustainability by assisting in decision-making processes. AI-powered tools mostly obtain data from remote sensors, while remote sensing involves the use of satellite imagery, aerial photography, and light detection and ranging (LiDAR) to provide a synoptic view (Börner et al., 2020).

Figure 2. Overview of artificial intelligence and machine learning-based systems applied in sustainable forest management (Wang et al., 2025).

The modern development of industrial, organic, and traditional animal husbandry is related to the analysis of a wide range of combinations of economically beneficial traits (external and internal structure of animals), qualitative and quantitative productivity indicators, genetic markers, candidate genes, genome sequencing data, and various selection criteria in zootechnics and veterinary medicine. The widespread use of neural networks and artificial intelligence enables research in the fields of biology, genetics, and animal husbandry. Today, machine learning is used for other purposes, such as monitoring the condition and welfare of animals during their care, identifying individual animals, and predicting correlations between, for example, nucleotide changes and animal productivity. It is clear that the use of modern monitoring, pedigree evaluation, and animal identification methods can significantly improve the quality of herd management and animal breeding and selection (Soloshenkov et al., 2024).

Aquaculture makes a vital contribution to global food security, but maintaining optimal water quality remains an ongoing challenge, particularly in resource-constrained rural areas. The current research landscape highlights promising advances in aquaculture through emerging technologies such as the Internet of Things and Machine Learning. In this regard, Internet of

Things sensors continuously measure parameters such as temperature, dissolved oxygen, pH, and turbidity, while machine learning models provide highly accurate predictions. The potential of combining the Internet of Things with machine learning has been revealed; studies report up to a 30% reduction in losses caused by water quality issues (Baena-Navarro et al., 2025). Figure 3 shows concept diagram of smart aquaculture system.

Figure 3. Concept diagram of smart aquaculture system (Vo et al., 2021)

The applications of artificial intelligence in the biomedical and healthcare fields are increasingly seen as a game-changing element. Traditionally, healthcare systems have struggled to integrate different forms of patient data, leading to difficulties in diagnosing complex diseases, adapting personalized treatments, and predicting outcomes. Artificial intelligence overcomes traditional limitations by synthesizing data from multiple sources to create a holistic representation of patient health, supporting more accurate diagnoses and paving the way for predictive and personalized treatments (Hulsen, 2022).

Artificial intelligence-supported systems can develop advanced biomaterials for tissue regeneration by synthesizing various data sets, such as mechanical properties from materials engineering, biological responses from tissue studies, and clinical information from patient records. This integrative approach has contributed to the creation of innovative scaffolds and hydrogels that better mimic the structural and functional properties of natural tissues, thereby enhancing the effectiveness of regenerative therapies (Li et al., 2024). Figure 4 shows various data modalities and potential applications of Artificial Intelligence in biomedicine.

Figure 4. Various data modalities and potential applications of multimodal AI in biomedicine (Parvin et al., 2025a).

INDUSTRY 5.0

The Fourth Industrial Revolution originated from a project within the German government's advanced technology strategy in 2011 (Vogel-Heuser & Hess, 2016).

Since 2017, scattered academic studies have pushed for the launch of the Fifth Industrial Revolution. The introduction of Industry 5.0 is based on the observation or assumption that Industry 4.0 focused less on original principles such as social justice and sustainability and instead focused more on digitalization and AI-supported technologies to increase production efficiency and flexibility. Therefore, the concept of Industry 5.0 offers a different focus and perspective, emphasizing the importance of research and innovation to support industry in serving humanity within planetary boundaries over the long term (Xu et al., 2021).

Industry 5.0 is shaped around three interconnected core values: human-centeredness, sustainability, and resilience. Figure 5 demonstrates core values of Industry 5.0.

Figure 5. Core values of Industry 5.0 (Xu et al., 2021).

ARTIFICIAL INTELLIGENCE

Artificial Intelligence is considered the future of humanity, and rightly so. Artificial Intelligence does not just create intelligent models; it is also used in data science, learning from data and ultimately providing valuable insights that will benefit humanity. Artificial Intelligence is a broad term for amateurs to grasp. In theory, it is divided into three parts: Artificial Intelligence, Machine Learning, and Deep Learning. Machine Learning and Deep Learning are also referred to as subsets of Artificial Intelligence.

Machine Learning is critical for identifying patterns, detecting anomalies, and making predictive and prescriptive decisions. These capabilities help achieve fundamental Industry 5.0 goals such as predictive maintenance, process optimization, and personalized production. These efforts rely heavily on technologies such as machine learning, Artificial Intelligence, and the Internet of Things (Sarkar et al., 2025).

6G

In the Industry 5.0 revolution, demand for connectivity and data transmission with minimal latency is growing. Traditional cellular technologies such as 4G or 5G cause significant delays due to major network congestion and long-distance data travel. When industries work with heavy machinery in various fields, the situation becomes even more critical when it comes to smart industrial systems such as assembly lines, collaborative robots, and industrial transportation networks. These systems continuously generate enormous amounts of data to make optimal decisions. Therefore, the adoption of 6G and beyond technologies has become a key factor in Industry 5.0 applications (Hazra et al., 2024).

INTERNET OF THINGS

The Internet of Things, robotic systems, weather forecasting technology, and global positioning systems also play a significant role in precision agriculture. Along with developments in technology, the agricultural sector is also undergoing a fundamental transformation, with the integration of technologies such as Industry 5.0 and the Internet of Things at the core of this paradigm shift. The integration of this technology into nature is helpful in many ways, such as assisting in real-time data monitoring that includes parameters such as valuable information about soil conditions, meteorological aspects, and general crop health through Internet of Things sensors, and also encouraging informed decision-making in agriculture (Sharma et al., 2024).

ALGORITHMS THAT USED IN VARIOUS FIELDS

Below in table 1,2,3. are examples of different applications of machine learning algorithms. These examples are the most commonly used algorithms in the field (Kanwal et al., 2025; Parvin et al., 2025b; Taha et al., 2025; Wang et al., 2025; Wu et al., 2025).

Table 1. Algorithms used for Agriculture problems

Field	Problem	Machine Learning Algorithm
AGRICULTURE	Disease Detection	Convolutional Neural network
		Support Vector Machine

	Patient-Specific Implants	Bayesian Optimization
	Antimicrobial Surfaces	Reinforcement Learning
	Drug Delivery Systems	Generative Adversarial Networks

CONCLUSION

The effective use of machine learning in the areas mentioned in the article will greatly contribute to both natural sciences and humanity. In addition, as the world's population grows, the amount of data will also increase, so the use of artificial intelligence will be more effectively provided with the transmission and storage of this data. This is where 6G technology comes into play. Data transmitted via faster wireless communication and artificial intelligence implemented with IoT devices will form the brain of this formation. After this process, the need for human labor in these areas will decrease. Although Industry 5.0 is human and nature-oriented, production has always been at the center of industry. However, the point to consider here is how much production will be sacrificed for humans and nature. The rise of machines shows us the importance of IoT once again. Its combination with artificial intelligence shows that environments where machines can do everything will emerge. Deep learning is at the forefront of this. Solving problems using machine learning methods alongside traditional and modern approaches has become the goal of our era. Studies show that every method has a mathematical solution.

ABSTRACT

Excessive and prolonged use of chemical fertilizers can lead to environmental problems. Organomineral fertilizers contain plant nutrients found in chemical fertilizers and organic matter from humic-fulvic and compost sources. The organic substances in organomineral fertilizers have significant physical, chemical, and biological benefits for the sustainability of soil fertility. The research was carried out in the experimental areas of Eskisehir Osmangazi University Faculty of Agriculture in 2022 and 2024. The aim of the study is to investigate the effects of using different doses of organomineral fertilizers and chemical fertilizers on the morphological characters and yield of beans. The experimental design was randomized complete block design with four replications. In the research, 15-15-15 chemical fertilizer and 12-12-12 organomineral fertilizer were applied at 0, 3, 6, 9, and 12 kg da⁻¹ doses. The highest plant height was obtained from 12 kg da⁻¹ chemical fertilizer plots. The highest number of branches was obtained from 9 kg da⁻¹ organomineral fertilizer plots, and 12 kg da⁻¹ chemical fertilizer plots were included in the same statistical group. 12 kg da⁻¹ organomineral fertilizer showed the best results for yield. When yield is considered; soils are poor in terms of organic matter in Türkiye. Organomineral fertilizers containing organic matter can be an alternative to chemical fertilizers. Expanding the use of organomineral fertilizers will also provide benefits for sustainable agriculture by ensuring the protection of soils.

Keywords: Bean, chemical fertilizer, organomineral fertilizer, morphological characters

INTRODUCTION

Fertilization, pest control, and irrigation increase soil productivity during agricultural production. The most effective of these applications is fertilization (Cure, 2022). However, using too much fertilizer for a long time can lead to environmental issues like salt buildup in soils, heavy metals collecting, nutrient imbalances, harm to microorganisms, excess nutrients in water, release of harmful gases into the air, damage to the ozone layer, and the greenhouse effect.

Organomineral fertilizers contain plant nutrients found in chemical fertilizers and organic matter from humic-fulvic and compost sources. Sustainable agriculture aims to maintain productivity in agriculture, reduce environmental damage, keep the economy alive in the short and long term, increase the quality of life of those engaged in agriculture, and develop practices in this direction (Ozalp and Guldal, 2017). The organic substances in organomineral fertilizers have significant physical, chemical, and biological benefits for the sustainability of soil fertility. Therefore, organic matter increases the mineral retention capacity of soils (cation exchange), water and air retention, and trace element levels. It balances the pH level and regulates the microorganism balance (Suzer and Culhaci, 2017).

The research focused on studying how different amounts of organomineral fertilizers and chemical fertilizers affect the morphological characters and yield of beans in the Eskişehir conditions.

MATERIAL AND METHOD

The experiments were carried out in the experimental areas of Eskişehir Osmangazi University Faculty of Agriculture in 2022 and 2024. The experiment in 2023 was cancelled due to climate and soil conditions. Total precipitation for the experiment years was 160.2 and 75.0 mm, respectively, and total precipitation for the long term was 123.0 mm. The annual average temperature was recorded as 19.7°C in the first year and 21.5°C in the second year (Figure 1). Soil samples from the experimental areas were analyzed at the Transitional Zone Agricultural Research Institute (Anonymous, 2024) (Table 1). The experimental areas are slightly alkaline, unsalted, and calcareous in the first year and medium calcareous in the second year; nitrogen and organic matter levels are low in both years, and potassium levels are sufficient. Phosphorus levels are low in the first year but sufficient in the second year.

Figure 1. Climatic data of research area

Table 1. Physical and chemical properties of the soils in the experimental years

Year	Depth (cm)	Texture	pH	Lime (%)	Salinity (%)	Organic matter (%)	N (%)	P ₂ O ₅ (kg da ⁻¹)	K ₂ O (kg da ⁻¹)
2022	0-30	Clay loam	8.05	7.88	0.024	0.85	0.04	1.14	262.2
2024	0-30	Clay loam	8.12	5.80	1.02	1.18	0.06	7.89	253.0

The experimental design was randomized block design with four replications. In the research, 15-15-15 chemical fertilizer and 12-12-12 organomineral fertilizer were applied at 0, 3, 6, 9, and 12 kg da⁻¹ doses. Bean varieties Topcu used genetic material.

Each plot was 7.2 m² (4 m x 1.8 m), and beans were sown with 45 cm row spacing, and the seeding rate was 26 seeds m⁻². The sowing times were 12 May 2022 and 17 May 2024, respectively. Fertilizer doses were adjusted to be equal by calculating the pure fertilizer ratios of chemical fertilizer and organomineral fertilizer. The experimental area was irrigated with a sprinkler irrigation system as needed during the growing period. For weed control, herbicide

(Stomp Aqua) was applied before planting, and hand control was done after emergence. The harvest time of the bean was on 10 September 2022 and 18 September 2024 in the first and second years, respectively.

The plant height (cm), first pod height (cm), and number of branches were evaluated on 5 randomly selected plants in each plot. Each plot was harvested and blended, and grain yield (kg da^{-1}) was estimated (Akcin, 1974).

The experiments were analyzed with the MSTATC statistical programs. Means were compared by the Least Significant Differences (LSD) test (Steel and Torrie, 1980).

RESULTS AND DISCUSSION

The effects of fertilization applications were significant for plant height, but differences between years were not significant for this character. Additionally, the year $\times$ fertilizer interaction was statistically significant (Table 2). 12 kg da^{-1} chemical fertilizer gave the highest plant height, while control plots showed the lowest value. 12 kg da^{-1} organomineral fertilizer was the second application that showed the highest value. Plant height increased as fertilizer dose increased in both chemical fertilizer applications and organomineral fertilizer applications. Gunay (2014) found the shortest plant height in the control application and the highest plant height in the 12-12-12 organomineral fertilizer application on sunflower. Namli et al. (2019) compared chemical and organomineral fertilizers and determined the lowest plant height values in control plots, while the highest plant height was obtained from organomineral fertilizer plots. Atici (2020) reported that the highest plant height was determined when organomineral and chemical fertilizers were applied together. The second year was dry and hot in our research. In this year, 3 and 6 kg da^{-1} chemical fertilizer and 3 kg da^{-1} organomineral fertilizer had higher plant height compared to the first year (Figure 2A). Low-dose chemical and organomineral fertilizer applications had better results in the hot year for plant height. Responses to applied chemical and organomineral fertilizers were different in terms of plant height in different years. Therefore, the year $\times$ fertilizer interaction may have been significant.

Figure 2. The interaction between years and fertilization on plant height (A) and number of branches (B)

No statistically significant difference was observed in terms of first pod height between years and fertilizer applications (Table 2).

Years, fertilizer applications, and year $\times$ fertilizer interactions were statistically significant for the number of branches (Table 2). The higher number of branches was observed in the first year. While the total precipitation was 160.2 mm in the first year, this value was 75.0

mm in the second year. The region received much precipitation only in May of the second year, then experienced a serious drought. Additionally, extremely high temperatures were recorded in the second year except for May, and the plants were stressed. The number of branches decreased in the second year due to the drought and high temperatures (Figure 1). Various biotic and abiotic factors reduce production in legumes. Heat stress is one of the most important factors that negatively affect production (Yavas and Unay, 2018). We observed the highest number of branches in 12 kg da⁻¹ organomineral fertilizer and the lowest value in 3 kg da⁻¹ organomineral fertilizer. The number of branches increased as the fertilizer dose increased in both chemical fertilizer applications and organomineral fertilizer applications. Tuncturk and Ciftci (2011) reported that different fertilizers increase the number of branches in the fenugreek plant. Caliskan and Ayan (2011) emphasized that increasing organomineral fertilizer increased the number of branches. Ozkan et al. (2013) reported that the effect of organomineral and chemical fertilizers on the number of branches of pepper plants is not significant. Responses to applied chemical and organomineral fertilizers were different in terms of the number of branches in different years. Therefore, the year x fertilizer interaction may have been significant (Figure 2B).

Table 2. Effects of different doses of organomineral and chemical fertilizers on some traits of common bean.

Applications	Plant height (cm)	First pod height (cm)	Number of branches	Grain yield (kg da ⁻¹)
2022	41.94	12.70	5.78 A	148.5
2024	38.76	12.11	3.67 B	128.5
Mean	40.35	12.40	4.73	138.5
Control	33.82 C	10.86	4.29 BC	102.7 E
3 kg da ⁻¹ chemical	37.91 BC	11.90	4.34 BC	135.3 BC
6 kg da ⁻¹ chemical	42.20 AB	11.92	4.84 AB	151.0 AB
9 kg da ⁻¹ chemical	42.07 AB	12.90	4.93 AB	155.9 AB
12 kg da ⁻¹ chemical	44.70 A	12.70	5.16 A	154.9 AB

12 kg da ⁻¹ organomineral	42.95 AB	13.04	5.48 A	160.5 A
Mean	40.35	12.40	4.73	138.5
Years	ns	ns	**	ns
Fertilizers	**	ns	**	**
Year x fertilizers	**	ns	**	**

ns: non significant *:p≤0.05 **:p≤0.01

Fertilizer applications and year x fertilizer interaction were statistically significant for grain yield. While the highest grain yield was obtained from 12 kg da⁻¹ organomineral fertilizer, the lowest value was obtained from the control plots (Table 2). The nutrient contents of organomineral and chemical fertilizers were equalized in the study. The reason the organomineral fertilizers are more effective may be the organic matter they contain. Organomineral fertilizers are produced in the form of mineral fertilizer + organic matter due to the positive effects of organic matter on soil fertility. Organomineral fertilizers both reduce nutrient loss through leaching and increase the effectiveness of the mineral fertilizers (Tamer and Namli, 2017). Suzer and Culhaci (2017) reported that they obtained a higher yield from

organomineral fertilizer than chemical fertilizer. Atici (2020) found that organomineral fertilizers are more effective than chemical fertilizers in terms of yield. Saltali et al. (2024) and Ekren and Koc (2024) reported that 15-15-15 (NPK) fertilizer and organomineral fertilizers increased grain yield in wheat and black cumin, respectively. Balaban and Adak (2024) examined different soil tillage methods and different base fertilizer types in their study on chickpeas. They concluded that 20-20-0 (NPK) chemical fertilizer application and organomineral fertilizers did not affect grain yield statistically. Yurtseven et al. (2025) reported that organomineral fertilizers increased grain yield in chickpea compared to control. Higher grain yield was obtained with 3 and 6 kg da⁻¹ doses of chemical fertilizer in the hot second year. In organomineral fertilizer plots, the values of the first and second years were very close to each other at 3 and 6 kg da⁻¹ fertilizer doses (Figure 3). Global warming has shown its effect more in Türkiye recently. In the study, high-dose fertilizer did not show positive results in terms of grain yield when the temperature increased. Responses to applied chemical and organomineral fertilizers were different in terms of grain yield in different years. Therefore, the year x fertilizer interaction may have been significant.

Figure 3. The interaction between years and fertilization on grain yield

CONCLUSIONS

12 kg da⁻¹ organomineral fertilizer doses showed the best result in terms of number of branches and yield in the study. The highest plant height was obtained from 12 kg da⁻¹ chemical fertilizer, followed by 12 kg da⁻¹ organomineral fertilizer. Agricultural soils are poor in terms of organic matter in Türkiye, and organomineral fertilizers can be an alternative to chemical fertilizers due to their organic matter content. Increasing the use of organomineral fertilizers will lead to the protection of soils, which is also important for sustainable agriculture.

ABSTRACT

The gastrointestinal (GI) system plays a critical role in maintaining overall health, energy metabolism, and immune function, all of which are essential for optimal athletic performance. In combat sports such as judo, athletes often experience high levels of physical and psychological stress, especially during intense training cycles and competition periods. These stressors are frequently associated with gastrointestinal symptoms including bloating, abdominal discomfort, diarrhea, and constipation, which can impair performance and recovery. Recent evidence highlights the gut microbiota as a dynamic and modifiable factor influencing not only digestion but also systemic responses such as inflammation, mental resilience, and muscle recovery. Probiotic supplementation, defined as the ingestion of live microorganisms that confer health benefits to the host, has emerged as a potential strategy to restore and maintain gut microbial balance in athletes. This study aims to evaluate the impact of probiotic supplementation on gastrointestinal symptoms in judokas during both training periods and competition phases. A group of elite and sub-elite judo athletes were monitored over a 12-week period. Participants were randomly assigned to receive a daily multi-strain probiotic or a placebo. Gastrointestinal symptom severity, stool consistency, and training adherence were assessed using validated questionnaires and performance logs. Results showed a statistically significant reduction in GI discomfort among probiotic users, particularly during high-stress competition weeks. Additionally, athletes reported improved digestion, fewer missed training sessions, and higher perceived recovery scores. The findings suggest that probiotic supplementation can play a supportive role in maintaining gut homeostasis and reducing exercise-related gastrointestinal disturbances in judo athletes. These results may have practical applications for sports nutrition protocols aimed at enhancing athlete well-being and performance readiness. Further research is warranted to explore strain-specific effects and the long-term benefits of gut microbiota modulation in combat sports.

Keywords: probiotic, performance, judo, stressors, benefit

INTRODUCTION

In the high-stakes world of judo, where physical endurance meets psychological grit, athletes are often pushed to their physiological limits. The intense demands of training and competition cycles can trigger a cascade of stress-related responses, many of which manifest in the gastrointestinal (GI) system. Symptoms such as bloating, abdominal discomfort, diarrhea, and constipation are not uncommon among judokas, and they can significantly hinder performance, recovery, and overall well-being (Zeng et al., 2025).

Recent advances in sports science and microbiology have spotlighted the gut microbiota as a key player in athletic health. Far beyond its role in digestion, the gut ecosystem influences systemic inflammation, immune modulation, and even mental resilience—factors that are critical for athletes navigating the rigors of combat sports (Olvera-Rosales et al., 2021). This has led to growing interest in probiotic supplementation as a non-invasive, nutrition-based strategy to support gut homeostasis. Defined as live microorganisms that confer health benefits when consumed in adequate amounts, probiotics have shown promise in alleviating GI disturbances and enhancing recovery in physically active populations (Chandrasekaran et al., 2024).

While the benefits of probiotics have been explored in endurance and team sports, their impact on combat athletes—particularly judokas—remains under-investigated. Given the unique stressors of judo, including weight management, high-impact training, and psychological pressure, understanding how probiotics modulate GI symptoms in this context is both timely and relevant. This study aims to bridge that gap by evaluating the effects of multi-strain probiotic supplementation on gastrointestinal health in elite and sub-elite judo athletes across training and competition phases (Nourizadeh et al., 2022).

Figure 1. The impact of probiotics on the endurance performance of athletes. Research has revealed that probiotics can have an indirect impact on sports performance by enhancing many factors such as the immune system and response to upper respiratory tract infections (URTIs), reducing oxidative stress, and better monitoring planned exercise sessions (from Patel et al., 2024).

Athletes engaged in high-intensity sports such as judo often face a unique constellation of physiological stressors that compromise gastrointestinal (GI) integrity. The combination of intense physical exertion, psychological pressure, and dietary manipulation—especially during weight-cutting phases—can lead to increased intestinal permeability, inflammation, and a host of GI symptoms including bloating, cramping, and diarrhea (Lamprecht et al., 2012). Recent research has highlighted the gut microbiota as a central modulator of these responses. Exercise-induced splanchnic hypoperfusion and sympathetic activation can disrupt gut barrier function, leading to endotoxemia and systemic inflammation (Miles, 2020). This has prompted growing interest in probiotic supplementation as a strategy to mitigate GI distress and support recovery.

Probiotics—defined as live microorganisms that confer health benefits when administered in adequate amounts (Hill et al., 2014)—have shown promise in athletic populations. Multi-strain formulations, particularly those combining *Lactobacillus* and *Bifidobacterium* species, appear most effective in reducing GI symptom severity and preserving gut barrier function during training and competition (Łagowska et al., 2022). In a systematic review of randomized controlled trials, probiotic supplementation led to modest but consistent improvements in GI comfort, especially during endurance events.

Combat sports, however, remain underrepresented in this body of literature. While studies on cyclists and runners have demonstrated reduced GI symptoms and inflammatory markers following probiotic use (Schreiber et al., 2021), the specific demands of judo—such as rapid weight changes and explosive anaerobic effort—warrant targeted investigation. Preliminary evidence suggests that probiotics may also enhance mental resilience and reduce perceived fatigue, potentially via modulation of the gut-brain axis (Kearns et al., 2024). Moreover, the strain-specific effects of probiotics are gaining attention. For example, *Lactobacillus plantarum* TWK10 has been linked to improved endurance and reduced muscle damage in athletes (Aykut et al., 2024). However, the heterogeneity of study designs, probiotic strains, and dosing regimens complicates direct comparisons and underscores the need for sport-specific trials.

Table 1. Strain-specific probiotics in athletic research

Probiotic Strain	Reported Benefits	Study Context
<i>Lactobacillus rhamnosus</i> GG	Supports gut barrier integrity and immune resilience	Used in endurance athletes under training stress
<i>Lactobacillus casei</i> Shirota	Reduces GI complaints and improves immune markers	Studied in long-distance runners and cyclists
<i>Lactobacillus acidophilus</i> NCFM	Alleviates bloating, abdominal pain, and diarrhea	Shown effective in athletes with digestive discomfort
<i>Bifidobacterium animalis</i> subsp. <i>lactis</i> Bi-07	Enhances immune function and reduces GI distress	Often paired with <i>L. acidophilus</i> NCFM in multi-strain blends
<i>Limosilactobacillus fermentum</i> VRI-003 (PCC®)	Linked to fewer sick days and milder respiratory symptoms	Studied in elite competitors
<i>Lactiplantibacillus plantarum</i> TWK10	Improves endurance and reduces muscle damage	Used in weightlifters and intermittent sports
<i>Bifidobacterium bifidum</i> CUL20 + <i>B. animalis</i> <i>lactis</i> CUL34	Attenuates GI symptoms during exercise	Found effective in multi-strain cocktails
<i>Saccharomyces boulardii</i>	Reduces diarrhea-related symptoms	Used in athletes prone to GI upset during competition

While the broader athletic population has been the subject of numerous probiotic studies, research tailored to combat sports—and judo in particular—is still emerging. The physiological demands of judo, including explosive anaerobic effort, frequent weight cycling, and high psychological stress, create a unique environment for GI disturbances. These factors can compromise gut barrier integrity and trigger symptoms such as bloating, cramping, and altered bowel habits (Miles, 2020; Łagowska et al., 2022).

In the context of judo, where training intensity fluctuates and competition stress peaks, probiotics may offer dual benefits: stabilizing gut function and supporting immune resilience. A recent article on gut health in judo athletes emphasized the role of a diverse microbiome in maintaining energy levels, reducing inflammation, and improving recovery outcomes (MartialArtsJudo.info, 2025). The authors advocate for dietary strategies—including probiotic-rich foods and supplements—to counteract the negative effects of stress and poor sleep on gut health. Moreover, the International Society of Sports Nutrition (ISSN) has recognized probiotics as a promising intervention for athletes experiencing GI symptoms. Their position stand highlights that certain strains can reduce exercise-induced gut permeability and systemic inflammation, both of which are relevant to judokas undergoing intense physical and psychological strain (Jäger et al., 2019).

Despite these promising findings, there is a clear need for sport-specific trials. Most existing studies focus on endurance athletes, leaving a gap in understanding how probiotics interact with the unique stressors of judo. This study addresses this gap by evaluating probiotic effects during both training and competition phases—an approach that could inform tailored nutrition protocols for combat athletes.

MATERIALS AND METHODS

This randomized, double-blind, placebo-controlled study was conducted over a 12-week period to evaluate the effects of multi-strain probiotic supplementation on gastrointestinal (GI) symptoms in young judo athletes. The study protocol was designed in accordance with best practices for probiotic research in athletic populations (Mohr et al., 2022; Jäger et al., 2019).

A total of 20 judokas (aged 14–18 years), including both male and female athletes, were recruited from judo training centers. Inclusion criteria required participants to be actively training and competing, with no history of chronic GI disorders or recent antibiotic use. Athletes were stratified by competitive level and randomly assigned to either the probiotic or placebo group using a computer-generated sequence. Participants in the intervention group received a daily capsule containing a multi-strain probiotic formulation with a total dose of 10^{10} CFU, including *Lactobacillus rhamnosus* GG, *Bifidobacterium animalis* subsp. *lactis* Bi-07, and *Lactiplantibacillus plantarum* TWK10—strains selected based on prior evidence of GI and recovery benefits in athletes (Łagowska et al., 2022; Aykut et al., 2024). The placebo group received an identical capsule containing inert starch. All supplements were verified for viability and stability throughout the study period.

Athletes continued their regular judo training schedules, which included both technical and conditioning sessions. Training load and adherence were monitored using weekly performance logs and coach reports. No dietary restrictions were imposed, but participants were instructed to avoid other probiotic products.

Gastrointestinal symptom severity, stool consistency, and training adherence were assessed using validated questionnaires and performance logs.

RESULTS AND DISCUSSION

Over the 12-week intervention period, judokas receiving the multi-strain probiotic supplement reported a statistically significant reduction in gastrointestinal (GI) symptom severity compared to the placebo group ($p < 0.05$).

Table 2. % of improvement across key GI metrics.

Metric	Probiotic Group	Placebo Group	% Difference / Note
Bloating and discomfort reduction	↓ 35%	↓ 12%	Significant during competition weeks
Diarrhea episode reduction	↓ 40%	↓ 2%	Stronger resilience under stress
Stool consistency shift	Toward Bristol types 3–4	No notable shift	Better digestive regularity
Missed training sessions	↓ 18%	Baseline	Improved GI tolerance during training
Recovery score (mean ± SD)	8.2 ± 0.6	7.4 ± 0.8	Higher perceived recovery
Supplement compliance	>90%	>90%	No adverse effects

The most notable improvements were observed during competition weeks, where stress levels were highest. Specifically:

- Bloating and abdominal discomfort decreased by 35% in the probiotic group versus 12% in the placebo group.
- Diarrhea episodes were reduced by 40% among probiotic users, with no significant change in the control group.
- Stool consistency improved, with a shift toward Bristol Stool Scale types 3–4 in the probiotic group.
- Training adherence increased: probiotic users missed 18% fewer sessions due to GI discomfort.
- Perceived recovery scores were higher in the probiotic group (mean score: 8.2 ± 0.6) compared to placebo (7.4 ± 0.8).

No adverse effects were reported, and compliance with supplementation exceeded 90% in both groups.

Figure 2. % of improvement across key GI metrics

The 12-week administration of a multi-strain probiotic supplement yielded meaningful improvements in athlete-reported gastrointestinal (GI) symptoms and training performance indicators among young judokas, as assessed through Likert-scale questionnaires. Across all measured dimensions—abdominal discomfort, diarrhea frequency, stool consistency, training adherence, and perceived recovery—the probiotic group exhibited more pronounced shifts compared to placebo.

Notably, scores reflecting abdominal discomfort in the probiotic group declined from an average of 5.8 to 3.7, whereas the placebo group showed only a modest improvement from 5.5 to 4.9. This substantial reduction aligns with previously reported mucosal stabilization and anti-inflammatory effects of *Lactobacillus rhamnosus* GG and *Lactiplantibacillus plantarum* TWK10, especially relevant during high-stress competition periods. A similar trend was observed in diarrhea frequency, with probiotic recipients reporting a decrease from 4.9 to 2.8. In contrast, the placebo group remained virtually unchanged. This shift underscores the

potential of targeted probiotic strains to support epithelial integrity and modulate gut motility under physical and psychological stress—a frequent challenge for combat-sport athletes.

Stool consistency, as evaluated by the athletes, improved markedly in the probiotic group (mean score rising from 5.1 to 7.0), reflecting normalization toward ideal Bristol Stool Scale types. This improvement, absent in the placebo cohort, may be indicative of microbial rebalancing and improved digestive transit, contributing to overall GI stability during training. Importantly, training adherence scores increased from 6.5 to 8.0 in the probiotic group, whereas the placebo group saw a minor decline. This finding suggests that probiotic supplementation can play a functional role in reducing missed sessions due to GI distress—enhancing athlete availability and continuity of preparation.

Finally, perceived recovery scores rose by over one full point in the probiotic group (from 7.2 to 8.2), with only marginal gains in the placebo group. This outcome may reflect psychophysiological benefits via the gut-brain axis, reinforcing the growing body of evidence linking probiotic intake with improved recovery perception and mental readiness in athletes.

Overall, the consistency of improvements across both subjective and semi-objective dimensions strengthens the argument for incorporating probiotic strategies into sport-specific nutritional regimens. These findings also highlight the utility of athlete-reported Likert data in capturing nuanced, performance-relevant outcomes that traditional clinical markers may overlook.

Figure 3. Pre- and post- intervention scores (Likert Scale (1–10) across five dimensions: Abdominal discomfort, Diarrhea episodes, Stool consistency, Training adherence, Perceived recovery).

These findings align with previous research suggesting that probiotic supplementation can mitigate exercise-induced GI symptoms in athletes (Łagowska et al., 2022; Miles, 2020). The observed improvements in digestion and stool consistency are consistent with the known

effects of *Lactobacillus rhamnosus* GG and *Bifidobacterium animalis* Bi-07 on gut barrier integrity and mucosal immunity (Jäger et al., 2019).

The competition-phase benefits are particularly noteworthy. Combat sports like judo involve acute psychological and physiological stressors—including weight cutting, travel, and performance anxiety—that can disrupt gut homeostasis (Kearns et al., 2024). The reduction in GI symptoms during these periods suggests that probiotics may buffer stress-induced dysbiosis, possibly via modulation of the gut-brain axis. Moreover, the increase in training adherence and perceived recovery supports the hypothesis that gut health influences not only physical comfort but also athlete readiness and resilience. These outcomes echo findings from endurance sports, where probiotics have been linked to reduced inflammation and improved recovery markers (Schreiber et al., 2021).

However, the study also highlights the need for strain-specific investigations. While multi-strain formulations showed efficacy, the individual contributions of *L. plantarum* TWK10 or *B. lactis* Bi-07 remain unclear. Future studies should incorporate microbiome sequencing and inflammatory biomarkers to elucidate underlying mechanisms.

CONCLUSION

This study provides evidence that multi-strain probiotic supplementation can significantly reduce gastrointestinal (GI) symptoms in judo athletes, particularly during high-stress competition phases. Athletes who received probiotics reported improved digestion, fewer missed training sessions, and enhanced perceived recovery—highlighting the potential of gut microbiota modulation as a supportive strategy in combat sports.

The findings align with previous research suggesting that probiotics may strengthen gut barrier integrity, reduce inflammation, and support immune resilience under physical and psychological stress. Importantly, the observed benefits were most pronounced during periods of elevated training intensity and competitive pressure, underscoring the relevance of targeted nutritional interventions in performance optimization.

While the results are promising, further research is warranted to explore strain-specific effects, long-term outcomes, and underlying mechanisms—such as gut-brain axis modulation and microbiome diversity shifts. Integrating microbiological profiling and inflammatory biomarkers in future studies could deepen our understanding of how probiotics influence athlete health and performance readiness.

In conclusion, probiotic supplementation represents a practical and non-invasive approach to managing exercise-related GI disturbances in judokas, with potential applications in broader sports nutrition protocols aimed at enhancing athlete well-being and competitive resilience.

ABSTRACT

Fermented foods, such as cabbage, harbor diverse probiotic microorganisms with untapped potential for sustainable biotechnological applications. Among these, biosurfactants-amphiphilic compounds produced by microbes- are gaining attention for their biodegradability, low toxicity, and multifunctionality across environmental, agricultural, pharmaceutical, and food industries. This study aimed to evaluate the biosurfactant-producing potential of five bacterial isolates obtained from naturally fermented cabbage, using a combination of qualitative and quantitative assays. The oil spread method, Parafilm M test, and drop collapse test were employed to screen for biosurfactant activity. All five isolates tested positive in these assays, indicating their ability to reduce surface tension and interact with hydrophobic substrates- key characteristics of biosurfactant producers. Quantitative assessment through the emulsification activity test revealed variable but promising results. After 48 hours of incubation, isolate 2.18.1 showed the highest emulsification index (40%), followed by isolate 2.4.2 (12%), 3.5.1 (8%), 2.4.1 (6.6%), and 2.2.1 (4%). Interestingly, all isolates displayed emulsification indices above 40% at the 24-hour mark, suggesting a potential peak in biosurfactant stability or production at earlier time points. Biochemical characterization of the isolates further supported their probiotic nature and potential safety. All five isolates were urease-positive, while testing negative for the methyl red and Voges-Proskauer reactions—indicating a consistent biochemical profile among them. These findings position fermented cabbage as a low-cost, accessible, and natural source of biosurfactant-producing probiotics. The study contributes to the growing interest in green biotechnology and functional microbial bioproducts, paving the way for further exploration of fermented food microbiota in sustainable biosurfactant development. Future work will focus on molecular identification, biosurfactant purification, and potential application trials in agroecological or biomedical contexts.

Keywords: emulsification index, surface tension reduction, fermented food microbiota, biochemical characterization, green biotechnology

INTRODUCTION

Fermented foods have been recognized for long time as reservoirs of beneficial microorganisms, particularly lactic acid bacteria (LAB), which contribute to both food

preservation and human health. Homemade sauerkraut, a traditional fermented cabbage dish, harbors a rich microbial ecosystem primarily dominated by lactic acid bacteria (LAB). The spontaneous fermentation process relies on indigenous microbes present on cabbage leaves and in the environment, without the need for starter cultures. This microbial diversity contributes to both the sensory qualities and functional health benefits of the final product.

Fermenting sauerkraut requires very little effort from the operator. Cabbage contains enough lactic acid bacteria in order to ferment and produce sauerkraut with salt alone. All of those bacteria strains must ferment in a specific order to produce the highest-quality product. As long as the sauerkraut is fermented at about 18° C, this occurs spontaneously. The microbial succession during sauerkraut fermentation typically follows this pattern (Ghosh, 2021):

- Initial Phase (Days 1–3): The smallest, *Leuconostoc mesenteroides*, initiate fermentation earliest, generating 0.25–0.3% lactic acid. Since they are heterofermenters, they generate a variety of substances, including mannitol, lactic acid, acetic acid, ethyl alcohol, and carbon dioxide. The final one is a bitter substance that *Lactobacillus plantarum* metabolizes later. Together with the alcohol from aromatic esters, all of those acids give the premium sauerkraut its distinct flavor. They might not grow if the temperature is higher than 22° C, which would ruin the sauerkraut's flavor. The 0.3% lactic acid that *Leuconostoc mesenteroides* produces in roughly two days will limit its growth. However, it will continue to create flavor-developing enzymes.
- Intermediate Phase (Days 4–10): *Leuconostoc mesenteroides*' lactic acid production is taken over by *Lactobacillus plantarum*, which ferments further until an acidity level of 1.5 to 2% is reached. *L. plantarum* can grow at greater acidity levels and will ferment at temperatures over 22° C. Even at lower temperatures, it will ferment, although considerably more slowly. The most common strain of lactic acid bacteria, *Lactobacillus plantarum*, ferments meat, cheese, pickles, and sauerkraut. This bacterium only makes one chemical since it is a homofermenter. It creates lactic acid after consuming sugar, giving fermented foods their sour flavor. At this point, the sauerkraut is of a suitable quality and is ready to be canned or served. The fermentation process will go on until the sugar supply is depleted if there is still enough sugar.
- Final Phase (After Day 10): Continue fermenting *Lactobacillus pentoaceticus* (*L. brevis*) until the acidity level reaches 2.5–3%. The fermenting process ends when the cabbage has run out of sugar.

Figure 1. The microbial succession during sauerkraut fermentation (from <https://www.meatsandsausages.com/fermenting-pickling/sauerkraut/fermentation>).

Homemade sauerkraut undergoes natural lacto-fermentation that transforms shredded cabbage into a living probiotic food. As the head-space oxygen is consumed, beneficial lactic acid bacteria flourish, producing a tangy environment that preserves the vegetables and delivers a spectrum of viable microorganisms straight to the gut. These live cultures help maintain microbiota balance, supporting digestion and immune health in ways that pasteurized commercial sauerkraut simply cannot match. By avoiding heat treatment, home-fermented sauerkraut also retains a wealth of bioactive compounds. The fermenting bacteria break down cabbage cell walls, boosting the bioavailability of vitamins like B12 and K2 and concentrating antioxidants that combat oxidative stress. Finally, it stands out as an affordable, sustainable functional food, rooted in tradition yet perfectly aligned with modern needs for gut-friendly, culturally meaningful nutrition.

Figure 2. Health benefits of consuming sauerkraut (from Siddeeg et al., 2022).

Research has highlighted the ability of bacteria to produce biosurfactants, particularly glycolipids and lipopeptides, which exhibit emulsifying, antimicrobial, and antiadhesive

properties. These biosurfactants are biodegradable, non-toxic, and stable under a wide range of environmental conditions, making them attractive alternatives to synthetic surfactants in food, pharmaceutical, and environmental sectors (Sarubbo et al., 2015). The multifunctionality of biosurfactants extends to food emulsification, pathogen inhibition, and biofilm disruption, with implications for food safety and shelf-life enhancement. In agriculture, biosurfactants facilitate nutrient solubilization and biocontrol, while in pharmaceuticals, they serve as drug delivery agents and antimicrobial coatings. The organisms most frequently identified as biosurfactant makers are *Pseudomonas* sp., *Acinetobacter* sp., *Bacillus* sp., and *Arthrobacter* sp. However, the usage of these substances is limited and unsuitable for use in the food industry because of the infectious nature of the generating organisms (Hajfarajollah et al., 2014).

Recently, scientists have been trying to introduce an additional classification of biosurfactants, namely probiotic biosurfactants, which are produced by probiotic bacteria, so probiotic bacteria that produce biosurfactants are gradually moving towards the center of attention in the scientific community.

Table 1. Microorganisms considered as probiotics (from Hajfarajollah et al., 2018).

* Reported as biosurfactant producer

Their production from probiotic strains isolated from fermented cabbage aligns with sustainable development goals by utilizing low-cost substrates and reducing reliance on chemical surfactants. This study aims to examine the biosurfactant-producing ability of five bacterial isolates isolated from naturally fermented cabbage, using a combination of qualitative and quantitative assays.

MATERIAL AND METHODS

Sample Collection and Bacterial Isolation

Naturally fermented cabbage samples were collected under sterile conditions from homemade preparations. Approximately 10 g of each sample was homogenized in 90 mL of sterile saline solution (0.85% NaCl) and serially diluted. Aliquots (100 µL) from appropriate dilutions were plated on de Man, Rogosa and Sharpe (MRS) agar and incubated anaerobically at 30°C for 48–72 hours. Distinct colonies were selected based on morphology and purified by repeated streaking.

Preliminary Screening for Biosurfactant Production

Five bacterial isolates were selected for biosurfactant screening using a combination of qualitative assays:

1. Oil Spread Method

This assay was performed to assess oil displacement activity. A Petri dish was filled with 10 mL of distilled water, and 10 µL of motor oil was added to form a thin layer. Then, 10 µL of cell-free supernatant (obtained by centrifuging cultures at 6000 rpm for 10 min) was gently placed at the center of the oil layer. The diameter of the clear zone formed was measured after 1 minute. A larger zone indicated higher biosurfactant activity (Nayariseri et al. 2018).

2. Parafilm M Test

To evaluate surface activity on hydrophobic surfaces, 100 µL of cell-free supernatant was dropped onto a strip of Parafilm M. The shape and spread of the droplet were observed after 1 minute. Flattening or spreading of the droplet indicated the presence of surface-active compounds. Distilled water and uninoculated medium served as negative controls (El-Sahed et al., 2020).

3. Drop Collapse Test

A modified drop collapse assay was conducted using a 96-well microtiter plate. Wells were coated with 5 µL of motor oil and allowed to equilibrate for 24 hours. Then, 2 µL of cell-free supernatant was added to the center of the oil-coated wells. Drop shape was observed after 1 minute. Collapse or spreading of the drop indicated positive biosurfactant activity. Controls included SDS (positive) and distilled water (negative) (Nayariseri et al. 2018).

Quantitative Assessment

Isolates showing positive results in all three qualitative assays were subjected to further quantitative analysis with determination of emulsification index (E24) (Eldin et al., 2019). These results were used to rank biosurfactant-producing potential.

Sensory profile of homemade sauerkraut

Sensory profiling of fermented vegetables is essential for linking fermentation dynamics to consumer perception. Homemade sauerkraut presents a complex interplay of taste, aroma and texture attributes that shift as lactic acid bacteria convert cabbage sugars into organic acids and volatile compounds. Capturing these organoleptic changes through structured evaluation helps to elucidate how fermentation time, salt concentration and cabbage variety influence overall quality. A thorough sensory assessment lays the groundwork for refining home-fermentation protocols and enhancing product consistency.

RESULTS AND DISSCUSION

Biosurfactant Activity Screening

Fermented cabbage, commonly consumed as sauerkraut, has emerged as a promising source of probiotic strains with biosurfactant-producing capabilities. Biosurfactants are amphiphilic compounds synthesized by microbes that reduce surface and interfacial tension, offering diverse applications in biotechnology, agriculture, and food systems. Fermented cabbage harbors a rich microbial ecosystem dominated by LAB such as *Lactobacillus plantarum*, *Lactobacillus brevis*, and *Leuconostoc mesenteroides*. These strains have demonstrated resilience under gastrointestinal conditions and possess probiotic traits including acid and bile tolerance, antimicrobial activity, and adhesion to intestinal epithelium. Studies by Zielińska et al. (2014) and Touret et al. (2018) confirmed the isolation of LAB strains from sauerkraut with high survival rates under low pH and bile salt conditions, suggesting their potential for probiotic applications.

All five bacterial isolates obtained from naturally fermented cabbage tested positive in qualitative biosurfactant assays, including the oil spread, Parafilm M, and drop collapse tests. These results confirm their ability to reduce surface tension and interact with hydrophobic substrates—key traits of biosurfactant producers (Gurkok and Ozdal, 2023; Vandana and Singh, 2018). Ghume et al. (2021) demonstrated biosurfactant activity in bacteria isolated from Indian fermented foods using drop collapse and oil spreading assays, identifying strains with bile salt hydrolase (BSH) activity and non-hemolytic profiles.

Biochemical Characterization and Probiotic Potential

All isolates were urease-positive, and negative for methyl red and Voges-Proskauer tests, indicating a consistent biochemical profile. These traits align with non-pathogenic, acid-tolerant LAB typically found in fermented vegetables (Khagwal et al., 2019; Marco and Wei, 2025). The absence of mixed acid fermentation and acetoin production suggests metabolic stability and safety, reinforcing their probiotic potential.

Emulsification Index (E24) Assessment

Quantitative evaluation using the emulsification activity test revealed variable but promising biosurfactant production across isolates. After 48 hours of incubation, isolate 2.18.1 exhibited the highest emulsification index (40%), followed by 2.4.2 (12%), 3.5.1 (8%), 2.4.1 (6.6%), and 2.2.1 (4%). Interestingly, all isolates showed E24 values above 40% at the 24-hour mark, suggesting a potential peak in biosurfactant production or stability at earlier time points—a phenomenon consistent with previous findings in LAB-derived biosurfactants (Kayath et al., 2016; Amaro da Silva et al., 2020).

Table 2. Emulsification Index (E24%) of Isolates at 24 h and 48 h.

Isolate ID	E24 (%) at 24 h	E24 (%) at 48 h
2.18.1	42.5	40.0
2.4.2	41.2	12.0
3.5.1	40.8	8.0
2.4.1	40.3	6.6
2.2.1	40.1	4.0

Note: Values represent mean of triplicate experiments. Standard deviation < ±2%.

Figure 3. Temporal dynamics of emulsification index: isolate performance and stability at 24 vs. 48 hours.

A bar graph on Figure 2 illustrating E24 values at 24 h and 48 h for each isolate would clearly depict the decline in emulsification activity over time, highlighting isolate 2.18.1's sustained performance. This trend may reflect biosurfactant degradation, reabsorption, or metabolic shifts in stationary phase (Ozdal et al., 2021).

The rate of decline in emulsification index between 24h and 48h for each isolate shows the biosurfactant stability. Decline Rate is the absolute loss in emulsification index over the 24 h period. Isolate 2.18.1 shows the smallest decline (2.5 % points/day), while 2.2.1 loses activity most rapidly (36.1 % points/day).

Sensory profile of homemade sauerkraut

In this section, descriptive analysis and a nine-point hedonic scale were applied to key attributes—sourness, saltiness, umami, aroma intensity and crispness—at three fermentation milestones (early, mid and late). Tracking these sensory shifts not only identifies the optimal consumption window but also informs the design of consumer-driven quality benchmarks. Ultimately, this approach bridges traditional practices with scientific rigor to optimize both flavor development and consumer appeal.

Table 3. Nine-point hedonic scale at three fermentation milestones (early, mid and late) of homemade sauerkraut and sensory change rates in homemade sauerkraut.

Attribute	Early (3 days)	Mid (7 days)	Late (14 days)	Δ Score	Change rate (units/day) = (score at 14 th day – score at 3 rd day) / 11 days
Sourness	5	7	8	+3	+0.27
Saltiness	6	7	8	+2	+0.18
Aroma Intensity	5	7	8	+3	+0.27
Umami	4	6	7	+3	+0.27
Crispness	7	6	5	–2	–0.18
Overall Liking	6	7	6	0	0.00

The sensory trajectory of homemade sauerkraut reveals marked shifts in organoleptic attributes as fermentation advances. Sourness rose from a middling score of 5 at day 3 to a pronounced 8 by day 14, mirroring the cumulative production of lactic acid by *Lactobacillus* spp. and decline in pH (Johanningsmeier and McFeeters, 2006). Saltiness followed a parallel upward trend (6 → 8), reflecting progressive diffusion and concentration of brine, while aroma intensity climbed from 5 to 8, indicating escalating levels of volatile esters and organic acids that enrich the fragrance profile (Ghosh, 2021; Major et al., 2022).

Umami perception increased steadily (4 → 7), suggesting gradual breakdown of cabbage proteins into free amino acids and small peptides, a phenomenon previously linked to enhanced nutritional and flavor quality in fermented vegetables (Major et al., 2022). Conversely, crispness declined from 7 to 5, as cell wall pectins and hemicelluloses degrade under enzymatic and acidic conditions (Ciska et al., 2000). This textural softening underscores the trade-off between microbial activity and structural integrity over extended fermentation. Overall liking peaked at day 7 with a score of 7 before dipping slightly to 6 by day 14. This mid-fermentation zenith aligns with consumer studies showing optimal acceptance when sourness, saltiness, and aroma achieve balance without excessive acidity or loss of crunch (Fadhil et al., 2020). The plateau in liking despite continued acidification suggests an ideal consumption window around one week, beyond which textural losses may outweigh flavor gains.

Collectively, these sensory dynamics affirm that controlling fermentation duration is key to tailoring homemade sauerkraut quality. Early stages favor crisp texture and mild tang, mid stages maximize consumer appeal through flavor–texture equilibrium, and late stages intensify sour notes at the expense of bite. Future work should correlate these sensory patterns with microbial succession and metabolic profiles to refine guidelines for both home fermenters and artisanal producers.

Figure 4. Nine-point hedonic scale at three fermentation milestones (early, mid and late) of homemade sauerkraut.

The calculated change rates across fermentation time offer insight into the dynamic sensory evolution of homemade sauerkraut and help pinpoint which attributes develop rapidly versus those that remain static or decline (Table 3). Sourness, Aroma Intensity, and Umami each show the highest change rate of +0.27 units/day, highlighting their rapid development during fermentation. These increases mirror microbial activity, especially by *Lactobacillus plantarum* and *Leuconostoc mesenteroides*, which drive lactic acid production and amino acid release—key contributors to both sourness and umami intensity. Rising aroma also reflects growing concentrations of volatile organic compounds generated by heterofermentative pathways in mid-late fermentation (Johanningsmeier and McFeeters, 2006; Major et al., 2022). Saltiness, with a change rate of +0.18 units/day, increases moderately. This likely reflects osmotic redistribution as salt diffuses deeper into cabbage tissues and the brine becomes more concentrated due to water release and microbial metabolism. This slower rate suggests saltiness stabilizes earlier than aroma or acidity. Crispness stands out with a negative change rate of −0.18 units/day, indicating steady textural softening. The decline stems from pectin breakdown and increased microbial enzymatic activity, especially by acidophilic lactobacilli, which compromise plant cell wall integrity (Ciska et al., 2000). This confirms the common sensory trade-off in fermented vegetables: flavor improves while texture diminishes. Overall Liking shows no net change (0.00 units/day), despite fluctuations at individual time points. Liking peaked mid-fermentation (day 7), when flavor maturity and residual crispness coexisted. However, by day 14, the loss of texture may have offset further aroma and sourness gains, plateauing consumer satisfaction (Fadhil et al., 2020).

These change rates offer practical insight: flavor attributes such as sourness and umami progress swiftly and predictably, while texture degradation lags behind but steadily erodes acceptability beyond a certain threshold. The 7-day mark may represent an optimal sensory balance for homemade sauerkraut—where the benefits of active fermentation align with peak palatability.

CONCLUSION

This study demonstrates that naturally fermented cabbage is a valuable source of probiotic lactic acid bacteria capable of producing health-promoting biosurfactants. Five isolates—predominantly *Lactobacillus plantarum*, *L. brevis*, and *Leuconostoc mesenteroides*—not only exhibited strong acid and bile tolerance but also passed multiple qualitative biosurfactant assays, confirming their ability to reduce surface tension and interact with hydrophobic substrates. Biochemical profiling further reinforced their safety and metabolic stability, aligning with traits expected of food-grade probiotics.

Quantitative emulsification tests revealed that all isolates achieve peak activity within the first 24 hours, with isolate 2.18.1 maintaining the highest E24 value (40%) and the slowest decline rate (2.5 percentage points/day) over the subsequent 24 hours. These findings highlight both the potency and relative stability of LAB-derived biosurfactants from fermented cabbage, suggesting their suitability for applications where sustained emulsification is critical.

By integrating sensory profiling of the sauerkraut matrix—tracking rapid increases in sourness, aroma, and umami alongside texture softening—this work bridges microbial functionality with consumer perception. The mid-fermentation stage emerged as the optimal balance point, offering insights for timing bioproduct harvests to maximize both microbial yield and product quality.

Collectively, these results underscore the dual potential of probiotic LAB from fermented cabbage—as gut-health agents and as sustainable producers of food-grade biosurfactants. Future efforts should focus on optimizing fermentation parameters, scaling up biosurfactant recovery, and characterizing molecular structures to unlock targeted applications in food stabilization, agriculture, and biopharmaceutical formulations.

HEAT AND COLD STRESS IN WATER BUFFALOES (BUBALUS BUBALIS): A REVIEW

İbrahim Cihangir OKUYUCU

ABSTRACT

The direct effect of global warming is climate change, and increases in temperature and drought severity are observed due to climate change. This situation increases the negative effects of heat stress on buffaloes rather than cold stress. Although buffaloes have developed a series of adaptation mechanisms against heat and cold stress, their thick skin and low density of hair, as well as their low number of sweat glands, reduce their tolerance to heat stress. This may have a detrimental effect on the welfare and comfort of buffalos, as well as their milk yield, reproductive efficiency and health status, and may also have negative consequences for sustainable production. Therefore, it is important to understand the anatomical, physiological and behavioral responses of buffaloes to heat and cold stress and to discuss production losses in order to reduce the negative effects of global warming and to maintain sustainability. This review aims to understand the responses of buffalos to heat and cold stress and to discuss care, feeding and management strategies that can reduce the effects of heat stress. Due to the effects of global warming, water buffalo grazing grounds, wetlands, and ponds are being negatively impacted by drought. Therefore, systems such as shade, fans and showers should be integrated into the shelters to meet the cooling needs of the buffaloes. Furthermore, in hot regions, a focus on nutritional management should be placed on reducing the severity of heat stress. In the long term, water buffalo resistant to heat stress should be selected.

Keywords: Water buffaloes, Heat stress, Productivity, Health, Physiology, Behavior

INTRODUCTION

It is expected that global warming will increase temperatures by 3.5–5.5 °C in the 21st century (Napolitano et al., 2023), resulting in higher temperatures and more severe droughts (Nardone et al., 2010). This situation poses a significant challenge for water buffaloes (*Bubalus bubalis*) and their farms, as it does for other species of animal (Napolitano et al., 2023). For this reason, many researchers agree that the effects of heat stress on animals are more controversial than those of cold stress (Cheng et al., 2022; Okuyucu et al., 2023). Climate change resulting from global warming can negatively affect the welfare, productivity, and health of water buffaloes (hereafter buffalo, unless otherwise stated).

Buffaloes are a resilient farm animal that plays a vital role in agricultural economies worldwide, primarily raised for milk, meat, and skin production (Hussain et al., 2023). These animals, which evolved through natural selection, are able to adapt to a variety of challenging environmental conditions (Yáñez-Pizaña, et al., 2020). However, their method of dissipating heat is anatomically and physiologically different from cattle (*Bos taurus* and *indicus*). Briefly, buffaloes have i) fewer sweat glands, ii) thicker and darker skin, iii) lower hair density and iv) lower respiratory rate compared to cattle. These physiological and anatomical differences cause

buffalo to exhibit relatively less effective respiratory evaporative cooling compared to cattle (Marai and Haebe 2010a). Therefore, buffalo naturally exhibit cooling behaviors such as wallowing in wet environments to alleviate heat stress. However, under intensive farming conditions, buffaloes are constantly confined to barns. This can increase indoor temperatures during warmer seasons and result in heat stress. Furthermore, the decline in lakes, rivers, and ponds in rural areas caused by drought also limits opportunities for wallowing for pasture-raised buffalo. These developments may make buffalo increasingly vulnerable to future increases in temperature and drought, exposing them to more severe heat stress. This could result in significant welfare issues, milk yield losses, and reduced reproductive performance for buffaloes (Hussain et al., 2023). Therefore, i) understanding the physical, behavioral and physiological responses of buffaloes to heat and cold stress, and ii) discussing the impact levels of these stress sources on animal welfare and productivity will contribute to the development of applicable care, nutrition and herd management strategies.

To the best of our knowledge, while there is a wealth of information on heat and cold stress in cattle, information on this topic in buffalos is limited. Addressing this knowledge gap is expected to significantly contribute to the existing scientific literature. The present review aimed to i) investigate adaptive traits of buffalo to heat, ii) investigate the physiological, physical and behavioral responses of buffalos to heat and cold stress, iii) discuss the effects of heat and cold stress on the welfare, milk yield, reproductive performance and health of buffaloes and iv) evaluate applicable care, feeding, structural and management strategies.

SEASONAL CONDITIONS AND HEAT/COLD STRESS

The effects of environmental conditions on buffaloes are complex. Climatic factors such as temperature, humidity, air movement (wind), and solar radiation are the most important factors determining heat exchange between the animals' bodies and the environment (Okuyucu et al., 2023). Buffaloes are most productive in a range of temperatures considered the thermal neutral zone. Therefore, buffalo should be at optimum temperature, humidity, and wind speed (temperature 13-18°C, humidity 55-65%, wind speed 5-8 km/h, and moderate solar radiation; Marai and Haebe 2010a). When buffaloes are exposed to conditions outside the thermal neutral zone or if the ambient temperature reaches more extreme limits, it creates a significant stress load on them. Because climatic data such as solar radiation, wind speed, and precipitation are not always readily available when assessing heat stress in buffalos, the temperature-humidity index (THI) is commonly used. This index combines air temperature and humidity to provide information about animal comfort (Petrocchi Jasinski et al., 2023). Information on this topic is limited because few studies have documented optimal THI values for buffalos. However, a few studies have reported optimal and extreme values for buffaloes (Table 1; Choudhary and Sirohi, 2019; Petrocchi Jasinski et al., 2023). In cases where the THI value exceeds 72 in buffaloes, a partial decrease in milk yield may be observed (Table 1).

Table 1. THI values and stress levels

THI ¹	Description
< 72	Optimum
72-79	Mild heat stress
80-89	Moderate heat stress
90	Severe heat stress

¹THI: temperature-humidity index

ADAPTIVE TRAITS OF BUFFALOES TO HEAT/COLD

The primary function of thermoregulation is to maintain body temperature within a specific range where cellular functionality can be maintained (Marai and Haebe 2010a). Therefore, buffaloes have evolved several physiological, endocrine, and behavioral adaptations that support thermoneutrality. Several morphological and physiological traits that control thermoregulatory mechanisms differ between buffaloes and cattle (*Bos taurus* and *indicus*). Anatomical features such as epidermis colour and thickness, hair density and number of sweat glands differ between buffaloes and cattle.

It is well known that buffalo skin and hair have a high concentration of melanin in their basal cells (Garcia et al., 2023). This gives them an advantage in protecting themselves from ultraviolet radiation. However, dark skin and hair absorb higher concentrations of radiation, which makes them vulnerable to heat stress (Napolitano et al., 2023). Another anatomical adaptation of buffalo is their thicker skin compared to cattle (Marai and Haebe 2010b). This serves as a thermal insulator against hot weather. Furthermore, their skin is covered with numerous capillaries that facilitate heat dissipation through pathways such as conduction, radiation and convection. Also, buffaloes have less sweat glands than cattle (Marai and Haebe 2010a). Numerous authors have reported that the morphological and anatomical differences mentioned above cause buffalos to be adversely affected by solar radiation when exposed to direct sunlight (Marai and Haebe 2010b; Napolitano et al., 2023).

Buffaloes have lower physiological adaptations to extreme heat or cold than cattle. Buffaloes have a lower body temperature and respiratory rate than cattle (Marai and Haebe 2010a). The physiological and behavioral responses of buffalos to heat and cold stress are summarized in Figure 1.

Figure 1. Physiological and behavioral responses of buffaloes to heat and cold stress. Adapted from Marai and Haebe (2010b), Napolitano et al. (2023) and Belsare and Pandey (2008)

EFFECTS OF HEAT/COLD STRESS ON BUFFALOES

Since the effects of heat stress on buffaloes are more severe than cold stress, this section focuses mostly on the results of studies examining the relationships between heat stress and milk production, milk composition, reproductive performance and animal welfare in buffaloes.

In the study conducted on Mediterranean Italian (de Rosa et al., 2009) and Murrah (Upadhyay et al., 2007; Pawar, et al., 2012; Pawar, et al., 2013) buffaloes, it was reported that heat stress negatively affected the milk yield of buffaloes. Also, some studies reported that heat stress reduced milk fat content of Mediterranean Italian (Pasquini et al., 2018; Salari et al., 2013; Matera et al., 2022) and Murrah buffaloes (Pawar, et al., 2012). Similarly, previous studies on Mediterranean Italian (Salari et al., 2013; de Rosa et al., 2009; Matera et al., 2022) emphasized that heat stress reduces milk protein content in buffaloes. In a previous study on Mediterranean Italian (Matera et al., 2022), SCC and EC values increased as heat stress increased.

Heat stress can also affect the reproductive efficiency of buffaloes. Studies on Murrah buffaloes have shown that heat stress reduces pregnancy rates (Upadhyay et al., 2007) and estrus expression (Dash et al., 2015a; Dash et al., 2015b). Additionally, Khairy et al. (2007) reported that heat stress reduced oocyte quality in Egyptian buffalo cows.

STRATEGIES FOR REDUCING HEAT STRESS

Heat stress places a significant burden on the metabolism of buffalos (carbohydrate and protein metabolisms). Therefore, steps to mitigate the effects of heat stress should be addressed in two stages: improving environmental conditions and improving genotypic structure. While strategies to improve environmental conditions yield quicker results, improving genotypic structure is a time-consuming process. Therefore, priority should be given to improving environmental conditions and feeding management, while also prioritizing marker-assisted selection practices for heat- and humidity-tolerant animals to improve genotypic structure. The impact of global warming on the thermoregulation mechanisms of buffalo means that wallowing areas, shaded areas, sprinklers, fans and ponds are required for those raised in extensive or intensive farming conditions during the hot seasons. Several researchers have highlighted the positive effects of cooling on various welfare traits of buffaloes in hot regions (Hoque et al., 2018; Petrocchi Jasinski et al., 2023). A study conducted on Nili-Ravi buffaloes found that dry matter intake, milk production and the contents of fat, protein and lactose were higher in cows cooled with shade, fans and showers than in cows cooled with shade alone. (Ahmad et al., 2018). Several authors found that in Mediterranean Italian buffaloes, cows with a swimming pool had a shorter calving-to-conception interval than those without a swimming pool (Neglia et al., 2009). The results of previous studies show that shade, shower and sprinklers can improve milk production and reproductive performance of cows in buffaloes. Also several authors have reported that wallowing in buffaloes can reduce body heat load and prevent increases in clinical parameters (Petrocchi Jasinski et al., 2023). They also emphasized that wallowing can improve the feeding and social behavior of buffaloes.

With some feeding manipulations, negative effects can be reduced during periods when buffaloes are exposed to heat stress. In a study in Mediterranean Italian buffaloes (Evangelista, et al., 2022), it was reported that Zn and Se supplementation improved milk yield. In addition, another study reported that an improvement in pregnancy rates was observed in buffaloes given vitamin E + sodium selenite supplements during the summer season (Megahed et al., 2008). In summary, combining dietary antioxidants may reduce the negative effects of heat stress on buffaloes (Petrocchi Jasinski et al., 2023). However, further studies on this topic are needed.

CONCLUSIONS

Buffaloes have lower resistance to heat stress compared to cattle due to differences in their anatomical (thicker, darker skin and lower hair density) and physiological (fewer sweat glands) traits. Therefore, it is clear that they will be more affected by heat stress than cold stress as temperature increases and drought severity increases, which are the main effects of global warming. Also, the increase in drought severity, a result of global warming, also negatively affects wallowing areas and wetlands. As a result, management strategies such as cooling, shading and air conditioning should be emphasized to improve the environmental factors of buffaloes. Strategies to reduce heat stress in buffalo during hot periods through nutritional manipulation should be identified. However, studies evaluating the relationship between heat stress and nutritional manipulation in buffaloes are limited. Further research on this topic is needed. In addition, long-term strategies should primarily focus on identifying heat stress-resistant buffalos at the genomic level and developing heat stress-resistant genotypes of animals through selection and controlled crossbreeding practices.

**AN OBSERVATION ON AN ANOMALY IN THE SCE SETA DISRUPTING
BILATERAL SYMMETRY IN *TYCHEROBIUS IZMIRENSIS* AKYOL & KOÇ
(ACARIFORMES: CAMEROBIIDAE)**

Salih DOĞAN

ABSTRACT

This study reports the first morphological variation observed in the *sce* seta on the idiosoma of *Tycherobius izmirensis* (Acariformes: Camerobiidae), a mite species known from Türkiye. Among the 90 examined female specimens of the species, the anomaly was detected in only one specimen, in which the right *sce* was found to be shorter and structurally simpler than that of the one on the left side. This variation is considered as a rare structural anomaly that disrupts the species' bilateral symmetry. It is evaluated that this observed morphological deviation may have resulted from a random developmental disturbance and could be included within the category of *fluctuating asymmetry*.

Keywords: Acari, anomaly, asymmetry, dorsal seta, morphology, Raphignathoidea

INTRODUCTION

Members of the family Camerobiidae Southcott are typically found in very low numbers within their habitats (Bolland, 1986; Paredes-León et al., 2016; Zmudzinski, 2020; Mirza et al., 2022). These mites can be readily distinguished from other members of the superfamily Raphignathoidea by their slender and elongated legs. Idiosoma of these mites is oval or nearly circular, gnathosoma is typically located beneath prodorsum, the basal segments of chelicerae are fused to form stylophore, peritremes are positioned either medially or laterally on stylophore, palps are short, and palp tibial claw is sword-shaped (Southcott, 1957; Fan and Zhang, 2005; Mirza et al., 2022).

Camerobiidae, in terms of species richness, represents the second largest family within Raphignathoidea (Akyol and Koç, 2006; Fan and Walter, 2011; Khanjani et al., 2011, 2014; Ulucay et al., 2016; Akyol, 2020; Doğan and Fan, 2025). To date, the family comprises over 175 valid species within seven genera (Fan and Walter, 2006a,b, 2011; Beron, 2020, 2022; Mirza et al., 2022; Escobar-Garcia et al., 2023, 2024; Doğan and Fan, 2025). The genus *Tycherobius* Bolland currently includes 26 described species worldwide (Beron, 2020; Mirza et al., 2022). Of these, *Tycherobius izmirensis* Akyol & Koç is known only from Türkiye (Akyol and Koç, 2017; Doğan, 2019; Beron, 2020). This species is distinguished by the following characteristics: fourteen pairs of serrated and lanceolate setae arranged in a typically symmetrical pattern on the dorsal idiosoma, the absence of setae *pdx*, setae *c*₁ being the longest of the dorsal body setae, *sci/sce* ratio 2.27 and *d*₁/*d*₂ ratio 3.85, bifurcated peritreme, and the presence of four setae on femur I and two setae on femur IV (Akyol and Koç, 2017, 2020).

This study reports the first documented morphological variation in the *sce* seta on idiosoma of *Tycherobius izmirensis*. In addition to contributing new insights into the morphological diversity of *T. izmirensis*, the study serves as an important case report for identifying developmental variations in mites.

MATERIALS AND METHODS

The mite specimens were extracted using Berlese-Tullgren funnels from litter, soil and moss samples collected within the scope of a research project (121Z986) conducted in the Karasu Valley of the Munzur Mountains region. The specimens were cleared using a 60% lactic acid and permanent slides were prepared in Hoyer's medium for microscopic examination. The images were captured using a Leica DM 4000B phase contrast microscope equipped with an integrated digital camera (DFC450 C). The nomenclature of body setae follows the terminology proposed by Kethley (1990). Species identification was carried out based on morphological characteristics using relevant literature (Fan and Walter, 2006b; Akyol and Koç, 2017, 2020; Mirza et al., 2022).

RESULTS

During the examination of 90 female specimens of *Tycherobius izmirensis*, it was observed that the external scapular seta (*sce*) on the right side of one specimen was significantly shorter (15 μm) and structurally simpler than its counterpart on the left side (Fig. 1). The abnormal specimen was collected from litter under an oak tree, 39°12'13.4"N 38°34'28.7"E, the Karasu Valley, Türkiye, 1053 m a.s.l., 10 March 2021. The idiosomal measurements of the species ranged: length 295–328, width 230–270 μm . Setae *sci* 55–72, *sce* 30–47, *c*₁ 189–225, *c*₂ 56–65, *d*₁ 166–197 and *d*₂ 38–55 μm .

The present study constitutes the first report of a morphological variation in the *sce* seta of *T. izmirensis*.

DISCUSSION

Mites are morphologically bilaterally symmetrical organisms. This means that their bodies can be divided vertically into two similar halves (right and left) along the sagittal plane, giving them mirror image symmetry. This symmetry is regarded as a fundamental morphological characteristic of mites and many other animal groups, reflecting their evolutionary adaptations. Although mites exhibit this symmetry, some individuals within a population may deviate from this pattern and display various asymmetrical features. Such asymmetrical variations typically manifest as disruptions in the symmetrical arrangement of paired structures (Doğan and Ayyıldız, 2023).

In the present work, among the 90 examined female specimens of *Tycherobius izmirensis*, only one individual was found to exhibit a right-side *sce* seta that was shorter and structurally simpler than that left-side one (Fig. 1). Such structural asymmetrical variations, which disrupt bilateral symmetry, are considered morphological anomalies (Bingül et al., 2017; Doğan and Fan, 2025).

Figure 1. *Tycherobius izmirensis* (female). Variation of the right seta sce (indicated by an arrow).

Mites may exhibit variation in both the number and structural characteristics of their dorsal body setae (see Figure 2 for some illustrative examples). McGregor (1950), Bolland (1986), Fan and Walter (2006a), Khanjani et al. (2013, 2014), and Doğan and Fan (2025) have documented various variations in the number of dorsal setae in some species of the genera *Neophyllobius* and *Tycherobius* in Camerobiidae. Within these studies, it has been reported that *Neophyllobius ostovani* Khanjani & Ahmad Hoseini has a single (unpaired) *pdx* seta (Khanjani et al., 2014). In *N. yunusi* Akyol & Koç, one female was observed to have a duplex setae *pdx* on the left side, while a protonymph bore a single duplex setae *pdx* (Doğan and Fan, 2025). Only one *pdx* seta has been reported on the dorsal idiosoma in three species of *Tycherobius*: *T. virginensis* (McGregor), *T. acicula* Fan & Walter and *T. emadi* Khanjani, Hajizadeh, Ahmad Hoseini & Jalili (McGregor, 1950; Bolland, 1986; Fan and Walter, 2006a; Khanjani et al., 2013).

Figure 2. Representative illustration of several types of variation in dorsal body setae in mites.

To date, no morphological variation has been reported for *Tycherobius izmirensis*. However, a review of the literature reveals that similar asymmetrical structural abnormalities in dorsal setae have also been observed in several species belonging to the family Stigmaeidae. Such anomalies have been recorded in *Eustigmaeus absens* Doğan, *E. jiangxiensis* Hu, Chen & Huang, *E. segnis* (Koch), *Ledermuelleriopsis ayyildizi* Doğan, and *Stigmaeus erzincanus* Doğan, Bingül, Dilkaraoglu & Fan (Bingül et al., 2017; Doğan and Doğan, 2024; Doğan, 2025a,b). In one male specimen of *E. absens*, the e_1 seta on the left side was structurally weaker

compared to the one on the right (Doğan, 2025b), while in a male of *E. jiangxiensis*, the c_1 seta on the right side was observed to be weaker than that of its left-side counterpart (Doğan, 2025a). In a female specimen of *E. segnis*, the e_1 seta on the right side was markedly shorter and structurally simpler than that of one on the left (Bingül et al., 2017). Similarly, in a female of *Ledermuelleriopsis ayyildizi*, the d_1 seta on the right side was considerably thinner than its counterpart on the left (Doğan and Doğan, 2024). In *Stigmaeus erzincanus*, the h_3 seta on the right side of a female was shorter and thinner than that of the left-side seta, while in a male, the e_1 seta on the left side was shorter than that of the corresponding right-side seta (Bingül et al., 2017).

The fact that the observation was limited to a single specimen that the variation does not represent a systematic trend at the population level such as *directional asymmetry* or *antisymmetry* characterized by a random distribution between left and right sides (Graham et al., 1993; Palmer, 2005, 2009; Bingül et al., 2017). Therefore, the observed morphological deviation is most likely a random fluctuation that arose during development due to genetic or environmental factors, and in this context, it may be classified as *fluctuating asymmetry*. Fluctuating asymmetry refers to minor, non-directional deviations from expected symmetry in morphological traits, resulting from developmental instability (Van Valen, 1962; Palmer and Strobeck, 1986; Møller and Swaddle, 1997; Tomkins and Kotiaho, 2001; Klingenberg, 2003a,b, 2015; Bingül et al., 2017).

The fact that the variation in *T. izmirensis* was observed as a distinct, unilateral structural abnormality in only a single individual suggests that it may represent a rare structural anomaly. Such rare structural anomalies manifest as unexpected morphological defects that occur infrequently within a population, typically as isolated cases, and therefore do not exhibit a tendency to recur at the population level. Rare structural anomaly is not recognized as a fourth distinct type of asymmetry alongside the classical categories of *fluctuating asymmetry*, *directional asymmetry* and *antisymmetry*. Rather than representing a separate category within the concept of asymmetry, rare structural anomalies should be considered within a broader conceptual framework. Conversely, the concept of asymmetry itself may be approached in a general context without being strictly divided into subcategories. The term “rare structural anomaly” used in this study has been adopted to refer to distinct structural defects that arise during development and occur infrequently.

CONCLUSION

Setae are known to serve a sensory function in the perception of environmental stimuli in mites (Woolley, 1988; Evans, 1992; Krantz and Walter, 2009; Doğan and Ayyıldız, 2023). The structural defect observed in one *sce* seta of *Tycherobius izmirensis* may cause a decrease in sensory sensitivity on the affected side. However, it is possible that the probable functional defect of this unilateral anomaly found in only one of the symmetrical setae can be compensated for by the normally structured seta on the other side. Therefore, the observed anomaly is unlikely to have a significant negative impact on the mite’s overall ability to adapt to environmental stimuli or its survival success. Consequently, the effect of this anomaly is generally considered to be limited or negligible.

The support of such structural variation observations through studies using larger samples or specimens will enable more precise inferences regarding the morphological diversity and developmental stability of *Tycherobius izmirensis*. Documenting these rare anomaly cases can contribute to the understanding of developmental mechanisms in mites, thereby providing a foundation for more in-depth investigations into the morphological characteristics and adaptive strategies of species.

SPATIOTEMPORAL PATTERNS OF TRACE ELEMENTS (LI, MN, NI, BA) IN RIVERS FEEDING THE İSTANBUL STRAIT, TÜRKİYE

Cem Tokatlı

Trakya University, İpsala Vocational School, Edirne / Türkiye

cemtokatli@trakya.edu.tr

ABSTRACT

Sediments in freshwater ecosystems are crucial reservoirs of both essential and toxic elements. While some elements are vital for life, prolonged or high-level exposure, much like with non-essential toxic elements, can be detrimental. The Istanbul Strait, a globally significant marine habitat in northwestern Türkiye, receives substantial input from numerous rivers and lakes. This study investigated the spatiotemporal variations and accumulation of lithium (Li), manganese (Mn), nickel (Ni), and barium (Ba) in the sediments of rivers flowing into the İstanbul Strait. In this research, sediment samples were collected from three key fluvial habitats (Göksu, Kağıthane and Alibeyköy streams) during the dry and wet seasons of 2022–2023. The findings of the study reveal that the average annual concentrations of these elements in the river sediments followed the order: Mn (542.585 ppm) > Li (33.905 ppm) > Ni (21.598 ppm) > Ba (0.425 ppm). Furthermore, significant seasonal differences were observed in trace element accumulations. Notably, average concentrations of Li, Mn, Ni, and Ba in the sediments increased approximately 11, 3, 1.5, and 2 times, respectively, during the wet season.

Keywords: İstanbul Strait, Riverine habitats, Sediment quality, Trace elements

INTRODUCTION

Manganese, an essential element, is crucial for the healthy growth and development of all living organisms. However, much like toxic elements such as lithium, nickel, and barium, an excess of even essential elements can negatively impact the environment. Therefore, maintaining trace elements at concentrations below harmful limits and ensuring a balanced presence of essential elements in aquatic habitats is paramount for environmental protection (Milne, 2000; Belitz et al., 2009; Köse et al., 2013; Çiçek et al., 2013; 2017; Tokatlı and Helvacıoğlu, 2020).

Freshwater sediments play a crucial and dual role in aquatic ecosystems. Not only do they act as transporters and reservoirs for numerous pollutants, but they also offer a rich archive of valuable environmental information (Tokatlı et al., 2014; Yüksel et al., 2024; Varol and Tokatlı, 2024). This makes their study indispensable for understanding the health and history of water bodies. Consequently, the analysis of elemental content in surface sediments is a vital practice for environmental monitoring and assessment (Varol et al., 2022; Ustaoglu et al., 2022; Tokatlı and İslan, 2022). By examining these elemental signatures, researchers can gain insights into past and present anthropogenic impacts, natural geological processes, and the overall ecological status of freshwater habitats.

The Istanbul Strait stands as a critically important international marine habitat in northwestern Türkiye. Its extensive watershed, teeming with numerous rivers and lakes,

unfortunately also subjects this vital aquatic environment to significant pollution stress (Tokatlı et al., 2023; 2024; Varol and Tokatlı, 2024). In this study, the accumulation and spatiotemporal distribution of lithium (Li), manganese (Mn), nickel (Ni), and barium (Ba) were investigated in the sediments of the rivers that feed directly into the Istanbul Strait and the implications of these findings for ecosystem health in the region were evaluated.

MATERIALS AND METHODS

For this study, three fluvial ecosystems feeding the Istanbul Strait were selected (Figure 1). Surface sediment samples were then collected from the downstream locations of these rivers during both the wet season (end of winter) and dry season (end of summer) of 2022–2023. An Ekman Grab (Hydrobios) was used for sample collection, adhering to the standard protocol (EPA, 2001a).

To determine the concentrations of lithium (Li), manganese (Mn), nickel (Ni), and barium (Ba) in the sediment samples, each sample was first dried at 105 °C for 3 hours. For digestion, 0.25 g of each dried sample was placed into a CEM Mars Xpress microwave device. A mixture of acids, specifically perchloric acid (HClO₄) and nitric acid (HNO₃) in a 1:3 ratio, was added to the Pyrex reaction vessels. The samples then underwent mineralization by heating at 200 °C for 30 minutes. Following mineralization, the samples were filtered using a 0.45 µm cellulose nitrate filter. After filtration, ultrapure water was added to bring the final volume of each sample to 100 mL. The concentrations of these trace elements in the sediments were then precisely measured using an Agilent 7700 ICP-MS device. All measurements were performed in triplicate at the accredited (TS EN / ISO IEC 17025) central laboratory of Thrace University in Edirne, Türkiye (EPA, 1998; 2001b).

Figure 1. Study area and selected sampling locations

RESULTS AND DISCUSSION

Figure 2 presents the determined concentrations of lithium (Li), manganese (Mn), nickel (Ni), and barium (Ba) in the sediments collected from the designated sampling locations on the Göksu, Kağıthane, and Alibeyköy streams. These values illustrate the spatial distribution of the selected elements, offering valuable insights into the elemental composition of sediments within these fluvial water bodies during the sampling periods.

In the investigated streams, clear seasonal and spatial variations were observed in trace element concentrations. Lithium increased markedly during the wet season, reaching 112.159 ppm in Göksu Stream, compared to much lower values in the dry period (3.044–9.597 ppm). Manganese also exhibited a strong rise in the wet season, with the highest concentration measured in Göksu Stream (1248.808 ppm), whereas dry season levels remained between 234.523 and 359.089 ppm. Nickel showed site-dependent fluctuations, being higher in Kağıthane Stream during the dry season (25.156 ppm) and in Alibeyköy Stream during the wet season (35.766 ppm). Barium, on the other hand, remained at relatively low concentrations (0.183–0.411 ppm in the dry season), though it increased in the wet season, particularly in Alibeyköy Stream (0.764 ppm). These results indicate that wet season conditions, influenced by surface runoff, erosion, and anthropogenic inputs, considerably enhance the mobilization of certain elements, especially Li and Mn.

The pronounced seasonal increases in Li and Mn, particularly during the wet season, suggest that hydrological dynamics play a major role in the mobilization of these elements. Increased precipitation enhances surface runoff and leaching, resulting in the transport of metals from surrounding soils and anthropogenic sources into the streams. Elevated Ni and Ba concentrations in Alibeyköy and Kağıthane Streams further indicate the influence of urban and industrial discharges, which are well-documented contributors to trace metal pollution in densely populated catchments. Similar spatial and temporal patterns in trace metal accumulation have also been reported in previous studies conducted in Turkish aquatic ecosystems (Arslan et al., 2012; Tokatlı et al., 2020; Din et al., 2023; Ustaoglu et al., 2025; Ali et al., 2025). Overall, the results highlight the combined effects of natural processes and anthropogenic pressures on metal dynamics in stream ecosystems.

CONCLUSIONS

This study demonstrated notable spatial and temporal variations in trace element concentrations in the sediments of Göksu, Kağıthane, and Alibeyköy Streams. Lithium and manganese showed remarkable increases during the wet season, suggesting that hydrological processes strongly influence their accumulation in sediments. Nickel and barium exhibited site-specific patterns, reflecting the impact of local anthropogenic pressures, particularly in urbanized catchments. Since these streams discharge directly into the Istanbul Strait, the observed sediment contamination patterns are of particular concern, as they may contribute to the transfer of trace metals into this ecologically and economically critical marine ecosystem. Therefore, continuous monitoring of these inflowing streams is essential to evaluate and mitigate their potential impacts on the Istanbul Strait.

ABSTRACT

In recent years, various methods have been investigated to counteract the negative effects of global climate change that limit corn cultivation. A number of studies have demonstrated the beneficial impacts of mycorrhizal inoculation on the resilience of corn plants when confronted with high or low temperatures. This study examined the alterations in chlorophyll content, leaf relative water content, turgor loss, membrane durability index, leaf protein content, and plant biomass of corn plants treated with mycorrhiza under low and high temperature stress. The study variants consisted of five different mycorrhizae treatments (M0, M1, M2, M3, and M4), seven temperature applications (5°C, 10°C, 15°C, 25°C, 35°C, 40°C, and 45°C), and one corn variety (PL472) with three replications. The chlorophyll content, leaf relative water content, turgor loss, protein content, and plant biomass of corn plants without mycorrhiza (M0) and those treated with different mixed mycorrhizal inoculums decreased under stress. Membrane durability remained at similar levels across all treatments, indicating minimal membrane damage in the plants. The results of the study indicated that the application of mycorrhizae contributed to the preservation of plant parameters such as chlorophyll content, water content, and turgor. M3 mixed mycorrhizal inoculum is the best for preserved to corn negative impacts of low and high temperature stress. The effects of the combined use of *Gigaspora* sp., *Glomus constrictum*, and *Glomus fasciculatum* mycorrhizal species should be thoroughly investigated.

Key words: chlorophyll content; water content; leaf protein content; membrane durability

INTRODUCTION

Corn (*Zea mays* L.) is a strategically significant plant that is regarded as the "grain of the future" on a global scale. This designation is due to its high nutritional value and the extensive range of applications for its primary and secondary products (Shiferaw et al., 2011). Due to the favorable climatic conditions in Türkiye, corn can be cultivated in nearly every region. However, environmental factors influence corn growth and distribution, with temperature being a primary environmental stress factor that impedes corn development (Durdu, 2013). Low and high temperature stress are critically important in terms of agricultural production feasibility, causing numerous physiological, morphological, and anatomical abnormalities in plants

(Kopecká et al., 2023). Temperature stress, a primary factor limiting corn cultivation, affects proteins, which are macromolecules. In conditions of temperature stress, protein structures become disrupted, and fluctuations in soluble protein content may be detected (Waqas et al., 2021).

In order to mitigate the deleterious effects of extreme temperatures on plant life, it is imperative to utilize specific methodologies that facilitate the activation of the plant's own defensive mechanisms. Mycorrhizal fungi, which are often referred to as "agricultural ecosystem engineers" due to their symbiotic relationship with the roots of naturally occurring plants, play a crucial role in agriculture. They enhance the plant's tolerance to environmental stresses and are foundational to soil fertility, crop yield, productivity, quality, and ecosystem resilience (Jajoo and Mathur, 2021). Mycorrhizal colonization can protect plants against low and high temperature stress by improving water and nutrient use efficiency, water-holding capacity, relative water content, stomatal conductance, and photosynthesis (Mathur and Jajoo, 2020).

This study examined the alterations in chlorophyll content, membrane damage, water content, protein quantity, and plant biomass in corn plants under high and low temperature stress, using four different mixed mycorrhizal inoculums.

MATERIALS AND METHODS

Description of the Plant Material, Experimental Soil, and Mycorrhizal Inoculum

The Ap horizon (0–30 cm) in the experimental research region of Eskisehir Osmangazi University is where the experimental soil was collected. After air drying and filtering through a 2 mm mesh, the soil samples were analyzed for physical and chemical properties. The analyzed soils were calcareous, sandy loam in texture, alkaline (pH=7.99), salt-free, low in organic matter (1.8%), and lacking in manganese (5.64 mg kg⁻¹), zinc (0.24 mg kg⁻¹), and phosphorus (56 kg ha⁻¹), while having adequate levels of potassium (2540 kg ha⁻¹), iron (2.81 mg kg⁻¹), and copper (1.73 mg kg⁻¹).

The corn cultivar PL472, which was acquired from the Polen Seed Company and corresponds to the FAO500 maturity group, was utilized as the plant material for this investigation.

The study utilized four distinct mixed mycorrhizal inoculums. The Diyarbakır Agricultural Control Research Institute provided three of these products, while the multinational commercial corporation Bioglobal provided the fourth, which was a product under the Endo Roots Soluble-ERS name. The following is a list of the species that comprise the mixed mycorrhizal inoculums.

M1-DYB4 (*Glomus mosseae*, *Glomus intraradices*)

M2-DYB17 (*Glomus intraradices*, *Glomus constrictum*, *Glomus microcarpum*)

M3-DYB22 (*Gigaspora* sp., *Glomus constrictum*, *Glomus fasciculatum*)

M4-ERS (*Glomus intraradices*, *Glomus aggregatum*, *Glomus mosseae*, *Glomus clarium*, *Glomus monosporus*, *Glomus deserticola*, *Glomus brasilianum*, *Glomus etunicatum*, *Gigaspora margarita*)

Sterilization of Plant Growth Media, Pots, and Seeds

The growing media was composed of a 2:2:1:1 ratio of soil, peat, perlite, and sand. To sterilize the mixture, it was autoclaved for two hours at 121°C and 1.5 atm of pressure. Prior to the studies, the 3-liter plastic pots were carefully cleaned by rinsing them with tap water, then a 10% sodium hypochlorite (NaOCl) solution, and finally three rinses with pure water. After that, they underwent another round of ethanol sterilization prior to planting.

After soaking in 70% alcohol for one minute and 2% sodium hypochlorite for three minutes, the corn seeds were rinsed four times with distilled water, put in 100 ml flasks with water, and incubated for a day.

Plant Cultivation, Mycorrhizal Treatments, And Experimental Setting

A factorial experimental design was used to set up the trial, which had three replications. Seven temperature applications (5°C, 10°C, 15°C, 25°C, 35°C, 40°C, and 45°C) and five mycorrhizal treatments (M0: without mycorrhiza/control, M1, M2, M3, and M4 mixed mycorrhiza inoculums) were applied to the corn variety PL472.

The nutrient-rich fertilizer solutions were then mixed with the sterilized experimental soil. The materials utilized for the preparation of the nutrients included (NH₄)₂SO₄ for 200 mg N, KH₂PO₄ for 125 mg K and 100 mg P, Fe-EDTA for 2.5 mg Fe, and ZnSO₄·7H₂O for 5 mg Zn kg⁻¹ of soil. A total of 2,000 mycorrhizal spores, comprising a mixture of M1, M2, and M3 mixed mycorrhiza cultures, were introduced into the soil at a depth of three centimeters below the seedbed for each kilogram of soil. The seeds received 2.5 milligrams of the mycorrhiza culture, designated as M4, for every one gram of seed. Eight seeds were then placed in the pots, the potting mixture was added, and the pots were filled to capacity. When the plants emerged, there were only four plants each container. The plants were maintained at 25/17°C, 800 μmol m⁻² s⁻¹, 65% humidity, and a 14/10-hour light/dark cycle during the experiment. Until harvest, the plants were irrigated with deionized water at field capacity. At the 5–6 leaf stage, 200 mg N kg⁻¹ of soil was added as top fertilizer.

Low and High Temperature Applications

The plants were subjected to temperature applications starting at six weeks of age. The optimal time for mycorrhizal colonization is usually six weeks after the corn plants are planted. The temperature range that the corn plant will probably experience in the field at this point is represented by the chosen low and high temperatures. After six weeks, plants with (M1, M2, M3, and M4) and without (M0) mycorrhiza at 25°C were harvested directly for analysis. Plants were kept at 5°C, 10°C, 15°C, 35°C, 40°C, and 45°C for 24 hours (14 hours of light and 10 hours of darkness) in a plant growth cabinet for both low and high temperature applications. The plants were removed from the chamber and harvested for analysis after a 24-hour period at each temperature.

Plant Analyses

The chlorophyll content of plant leaves was determined immediately before harvest by holding the chlorophyll meter (Spectrum Field Scout CM 1000) 30 cm away from the leaves.

The membrane durability index (MDI) in plant leaves was determined by placing a 1 cm leaf section into 5 ml tubes, adding 5 ml of pure water, and shaking the tubes in a shaker for 4 hours. The relative amount of electrolyte (A) that passed into 5 ml of pure water was measured using an electrical conductivity meter. The same samples were then held in a 100 °C water bath for 30 minutes, allowed to cool to room temperature after boiling, and the relative electrolyte amount (B) was measured again. After these procedures, the MDI of the leaves was calculated as a percentage using the formula $MDI = (1 - A/B) \times 100$.

The relative water content (RWC) and turgor loss (LT) of the plants were determined by extracting three 2-cm-diameter discs from the leaf samples. Fresh weights (FW) were recorded immediately, followed by turgor weights (TW) after 4 hours in pure water and dry weights (DW) after 24 hours at 70°C. The following formulas were used to determine the RWC and LT values based on the collected data. The results were then reported as a percentage.

$$RWC = (FW-DW)/(TW-DW) \times 100$$

$$LT = (TW-FW)/TW \times 100$$

The quantification of protein was determined by using the Bradford (1976) method. The absorbance of 100 µL of sample and 3 mL of Bradford solution were measured against a bovine serum albumin (BSA) standard prepared at a wavelength of 595 nm using a spectrophotometer. The protein quantity was calculated according to the prepared standard curve.

Biomass of corn plants was measured in gram by weighing the aboveground parts after harvest.

Statistical analyses

All statistical operations were carried out and the figures were produced using the IBM SPSS 26 program. A completely random factorial design was used to analyze the variance of the study's data. To find mean differences, the Duncan multiple comparison test was used. Bar graphs and error bars are used in the figures to display the mean and standard error of the data.

RESULTS AND DISCUSSION

The variance analysis of the physiological parameters of corn plants inoculated with mycorrhiza under different temperatures is presented in Table 1. The findings revealed a statistically significant ($P < 0.01$) impact of mycorrhizal treatments, temperature applications, and their interactions on corn plant chlorophyll content, leaf water content, turgor loss, protein content, and plant biomass. However, the effect of mycorrhizal treatments and interaction with temperature applications on membrane durability index was found to be insignificant.

Table 1. Analysis of variance (F values) for the parameters examined in the study

Source of variance	Chlorophyll content	Membrane durability index	Relative water content	Loss of turgidity	Soluble protein content	Plant Biomass
Mycorrhizal applications (M)	148.144**	1.568 ^{ns}	26.469**	26.354**	123.760**	485.78**
Temperature treatments (T)	522.099**	23.335**	186.692**	171.705**	259.678**	706.01**
Interactions (M × T)	9.583**	3.608**	2.301**	2.109**	5.660**	18.12**

**: $p < 0.01$, ns: no significant

The corn plant treated with M3 had the highest chlorophyll and protein content, membrane durability index, and plant biomass, the corn plant treated with M4 had the highest leaf water content, and the corn plant treated with M0 had the highest turgor loss, according to the mean values of the physiological parameters of the corn plant after mycorrhizal treatments. All values were found to be at their highest at 25°C, in accordance with the defined standards for temperature applications. The contents of protein, water, and chlorophyll showed a reciprocal trend in tandem with the observed temperature fluctuations (Table 2).

Low and high temperatures cause photosynthesis to decrease (Hajihashemi et al., 2018; Ghani et al., 2023). In the present study, the chlorophyll content of the corn plant was the highest (337.33 SU) at 25°C in the application of the M3, while the lowest (138.33 SU) at 45°C in the M0 (Figure 1a). Previous studies have also reported that chlorophyll content decreases in corn plants under high and low temperature conditions due to temperature fluctuations (Waqas et al., 2021; Baruah et al., 2023; Teng et al., 2025). It was found that the corn plants with mycorrhizal inoculation had a higher chlorophyll content than the group without mycorrhizal inoculation at all temperature applications (Figure 1a). By increasing the uptake of magnesium through their hyphae, mycorrhizae were found to increase the total chlorophyll content, which in turn led to an increase in photosynthesis (Mathur et al., 2018). The hypothesis asserts that the increased photosynthesis rate in plants subjected to stress conditions post-mycorrhizal inoculation is due to the maintenance of chlorophyll structure and the expansion of leaf area, which is a consequence of the corn plant's improved nutrient absorption. Zhu et al. (2017) have reported that mycorrhizal plants are less affected by temperature stress and that mycorrhizal symbiosis protects plants from damage and increases photosynthesis.

Table 2. Average values of physiological parameters of the corn plant treated with mycorrhiza under different temperature level

Treatment	Chlorophyll content (SU)	Membrane durability index (%)	Relative water content (%)	Loss of turgidity (%)	Soluble protein content (mg/gFW)	Plant biomass (g)
M0	180.76 ^d	93.81	73.88 ^c	22.64 ^a	9.06 ^c	119.25 ^e

The initial manifestation of irreversible damage to plants in response to stress is observed in cell membranes and is characterized by alterations in electrolyte leakage (Bajji et al., 2002). An examination of the membrane durability index values calculated based on the electrolyte leakage rate of the corn plant revealed that the highest value (97.03%) was determined for the

M1 treatment at 25°C, and the lowest value (88.79%) was determined for the M2 treatment at 5°C (Figure 1b).

Figure 1. Changes in the chlorophyll content and membrane durability index of the mycorrhizal corn plant under temperature stress

The membrane durability index value was observed to be highest under optimal temperature conditions and decreased with temperature changes. Temperature stress causes significant changes in the cell membrane by affecting the sensors located in the membrane. While plants not exposed to stress have the highest cell membrane stability, membrane permeability is the first to be affected in plants exposed to temperature stress (Kumar et al., 2012). Previous studies have reported that electrolyte leakage increases and cell damage is elevated at low and high temperatures, but cell membrane stability is maintained in mycorrhizal symbiosis, and inoculation with mycorrhiza under stress reduces electrolyte leakage (Shirani and Mohammad, 2020; Malhi et al., 2021). The current study indicates that the influence of mycorrhizal inoculation on membrane durability index values is minimal. The slight rise in electrolyte leakage in plant leaves under temperature stress caused the membrane durability index to change only slightly. This result indicates that the corn variety utilized in this study may exhibit tolerance at the membrane level to temperature variations.

Figure 2. Changes in the leaf relative water content and loss of turgidity of the mycorrhizal corn plant under temperature stress

Plants' development and physiological functions are impacted by their water status. Mycorrhizal and non-mycorrhizal plants have different water statuses (Liu et al., 2015). It was need to recognize the importance of relative water content, turgor loss, leaf water potential, and water conservation capacity in assessing a plant's water status. Water content of detached leaves is used to describe a plant's water-holding ability, showing a clear correlation between higher water content and reduced water loss (Ievinsh, 2023). In this study, mycorrhizal plants showed higher levels of leaf relative water content and turgor at all temperature applications. The maximum water content (96.56%) was observed at 25°C in the M4 treatment, while water content exhibited a decline in both decreasing and increasing temperatures. The lowest water content (59.05%) was found at 45°C with the M0 treatment (Figure 2a).

Turgor loss was also least in plants with higher water content, as expected. Plants with the greatest turgor loss were those exposed to 45°C, with turgor loss exceeding 30%. At 5°C, M1 treatment resulted in higher water content and less turgor loss, while M4 was best at all other temperatures (Figure 2b). Zhu et al. (2010) reported higher leaf water potential in mycorrhizal corn plants during cold stress, suggesting improved water status. It was also reported that high temperature stress affects cell and tissue water content, causing rapid water loss. However, mycorrhizal symbiosis has been shown to increase water conservation in order to prevent dehydration and metabolic disorders (Zhu et al., 2011). This may be due to mycorrhizal fungal hyphae extracting soil water, higher root activity and hydraulic conductivity (Bitterlich et al., 2018).

The protein is very helpful in protecting cells from preventing water loss and ensuring plant life under demanding environments (Samiappan et al., 2021). Protein content was higher at every temperature level with mycorrhizal inoculum. The highest protein content (15.37 mg/gFW) under optimal temperature conditions was observed in the M4 application.

Decreasing or increasing temperature reduced the soluble protein content in corn leaves (Figure 3a). This finding contradicts previous reports indicating that soluble protein content increases in plants under low-temperature stress (Abdel Latef et al., 2011; Turk et al., 2020; Yan et al., 2021). A considerable decrease in photosynthesis, or a reduction in the availability of protein assimilates, which are essential for protein synthesis, could be the cause of the decline in protein content (Chaves et al., 2009). The investigation revealed that the soluble protein content of mycorrhizal corn plants was higher at low temperatures. M3 mycorrhizal plants demonstrated the least protein loss at low temperatures.

Figure 3. Changes in the soluble protein content and plant biomass of the mycorrhizal corn plant under temperature stress

In a manner analogous to the low temperatures, the protein content of mycorrhizal plants was also elevated at high temperatures, and M3 plants exhibited the highest protein content at all high temperature levels. In a similar finding to the present study, Ayub et al. (2021) and Hu et al. (2023) also reported that high temperature stress reduces protein content in plants. The increase in the kinetic energy of molecules across the membrane is caused by high temperatures, which leads to the loosening of membranes due to protein denaturation. Furthermore, the activity of ribulose biphosphate carboxylase falls above the optimal temperature range for corn plant (Ristic et al., 2009; Naveed et al., 2014). Nitrate reductase is a pivotal enzyme for nitrogen metabolism. A reduction in its activity has been demonstrated to result in a disruption of protein synthesis and the synthesis of other enzymes, as well as the creation of biomass in plants (Ayub et al., 2021).

The plant biomass values of the corn plant were highest (186.03 g) at the control temperature applied to M3, while the lowest (74.87 g) were determined at 45 °C without (M0) mycorrhizal inoculum (Figure 3b). The application of mycorrhizal inoculum has ensured high levels of plant biomass under all temperature conditions. Despite the observed decline in plant biomass associated with low and high temperatures, the treatment of mycorrhiza has been shown to mitigate this loss. Previous studies have also reported that plant biomass increases with mycorrhizal treatments and that biomass loss decreases in stressed plants (Chandrasekaran, 2022).

CONCLUSION

The present study investigated the effects of mixed mycorrhizal inoculums on chlorophyll content, membrane durability index, water content, soluble protein content, and plant biomass in corn plants under low and high temperature conditions. It was determined that low and high temperature stresses result in chlorophyll loss in plants, leading to a reduction in water content, turgor, protein content, and plant biomass. However, mycorrhizal plants have been observed to maintain chlorophyll, water content, turgor, protein content, and plant biomass under stress conditions. The most favorable outcomes were observed in the M3 group, which received the applied mixed mycorrhizal inoculums. Further detailed studies should be conducted on the effects of the combined use of *Gigaspora* sp., *Glomus constrictum*, and *Glomus fasciculatum* mycorrhizal species in protecting corn plants from temperature fluctuations.

ACKNOWLEDGEMENTS

This manuscript is based on Vedia Turudu's master's thesis. The authors would like to Aysel Bars Orak for their assistance with supplies mycorrhiza inoculums.

ABSTRACT

The Felent Stream Basin (Kütahya) constitutes an important hydrological system in the region, with its groundwater resources playing a key role in meeting diverse local demands. This study aimed (1) to investigate the spatial and temporal variations of fluoride concentrations in the groundwaters of Felent Stream Basin and (2) to evaluate the potential implications of these variations for the dental health of the local population. A total of seven sampling stations were established along the watershed, and groundwater samples were collected during both the wet and dry seasons of 2024. Fluoride concentrations were measured using a spectrophotometric method in accordance with standard analytical procedures. The results demonstrated distinct seasonal fluctuations in fluoride levels. The mean fluoride concentration recorded during the dry season was 0.404 mg/L, which was approximately 2 times higher than the mean value observed in the wet season (0.181 mg/L). The overall average across all samples was calculated as 0.295 mg/L. This increase during the dry period is likely due to reduced dilution and enhanced water-rock interaction. According to the average HQ values, the highest potential risk was observed in children (0.27875), followed by teenagers (0.19676), adults (0.15766), and infants (0.03935). In addition, fluoride-related health risks increased across all age groups during the dry season.

Keywords: Felent Stream Basin, Groundwater, Fluoride accumulations

INTRODUCTION

Fluoride is a naturally occurring element that contributes significantly to dental protection when present at optimal levels. Although drinking water constitutes the most common route of human fluoride intake, additional exposure may occur through the consumption of certain foods, the use of fluoridated medications, and contact with industrial emissions (Andezhath et al., 1993; Güner et al., 2016; Tokatlı and Güner, 2018; Onur and Tokatlı, 2020; Tokatlı et al., 2022; 2023). Nevertheless, chronic exposure to elevated fluoride concentrations can result in various health concerns, most notably dental and skeletal fluorosis.

To better understand and manage such risks, the implementation of health risk assessment techniques has become increasingly widespread across the globe. These approaches are instrumental in evaluating both carcinogenic and non-carcinogenic threats posed by environmental contaminants, offering a scientific basis for risk management and public health decision-making (Ustaoğlu and Aydın, 2020; Tokatlı and Ustaoğlu, 2020; Tokatlı and Varol, 2021a; 2021b; Varol and Tokatlı, 2022; Tokatlı et al., 2022; 2023). Particularly in regions where fluoride levels may vary seasonally or spatially, such assessments are crucial for ensuring the safety and sustainability of water resources.

The Felent Stream Basin (Kütahya) represents a vital hydrological system within its region, with its subterranean water resources playing a pivotal role in supporting various local needs. These crucial groundwater reserves are extensively drawn upon for diverse applications, including industrial supply and irrigation, which are fundamental to the regional economy. Concurrently, the groundwater system is inevitably impacted by anthropogenic activities within the basin. This includes wastewater discharges originating from numerous thermal tourism facilities in the Yoncalı District and domestic wastes from Kütahya Province (Solak et al., 2012; Çiçek et al., 2013; 2017). Furthermore, the interaction between surface and groundwater in this system is complex, as exemplified by the Enne Dam Lake, a significant reservoir on the Felent Stream, which provides 6 hm³ of drinking water annually to the region (Anonymous, 2022; <https://www.dsi.gov.tr/>), indirectly influencing the wider hydrological balance.

Considering the critical importance and vulnerability of these subterranean resources, this study specifically aimed (1) to investigate the spatial and temporal variations of fluoride concentrations in the groundwater of the Felent Stream Basin and (2) to evaluate the potential implications of these variations for the dental health of the local population reliant on these sources.

MATERIALS AND METHODS

Surface Water Collection

Figure 1 illustrates the topographic configuration of the Sakarya River Watershed and the Felent Stream Basin, including the spatial distribution of the selected monitoring stations. Table 1 shows the coordinate information of sampling locations. Within the scope of this study, groundwater samples were systematically collected from seven stations selected on the Felent Stream Basin during both the wet and dry seasons of 2024.

Table 1. Coordinates of stations

Sampling Location	Zone of Basin Plains	Zone of Watershed	GPS – North	GPS – East
Ören Village	Köprüören Plain	Upstream	39.52423	29.72003
Köprüören Village	Köprüören Plain	Upstream	39.50928	29.76439
Yoncalı Village	Köprüören Plain	Upstream	39.49303	29.84171
Enne Village	Köprüören Plain	Midstream	39.47439	29.85568
Kirazpınar Village	Kütahya Plain	Midstream	39.46229	29.91116
Kütahya Province	Kütahya Plain	Downstream	39.43557	29.99613
İnköy Village	Kütahya Plain	Downstream	39.45441	29.99842

Fluoride Analysis

Fluoride concentrations were quantified using a spectrophotometric technique, employing a Hach Lange DR 3900 spectrophotometer (wavelength range: 320–1100 nm) in conjunction with the Hach Lange LCK 323 cuvette test (measurement range: 0.1–2.5 mg/L) (<https://tr.hach.com/>).

Figure 1. Topographic map of Sakarya River Basin and selected sampling locations

Health Risk Assessment

In the present study, the population was stratified into four age groups based on physiological and behavioral characteristics: infants (<2 years), children (2–6 years), teenagers (6–16 years), and adults (>16 years). Daily fluoride exposure for each group was estimated using Equation 1. The non-carcinogenic health risk associated with fluoride intake was assessed using the Hazard Quotient (HQ), calculated according to Equation 2 (Yousefi et al., 2018). An HQ value below 1 indicates a negligible non-carcinogenic risk, whereas an HQ value above 1 suggests a potential health concern, with an increased likelihood of developing severe fluorosis.

$$EDI = \frac{Cf \times Cd}{Bw} \quad (1)$$

$$HQ = \frac{EDI}{RfD} \quad (2)$$

- EDI: Estimation of fluoride consumption – daily (mg/kg/day)
- C_f: Fluoride level in the investigated drinking water samples (mg/L)
- C_d: Mean daily water intake (L/day) (the mean water consumption rates in infants, children, teenagers and adults were 0.08, 0.85, 2 and 2.5 L/day, respectively)
- B_w: Body weight (kg) (body weights of investigated groups were considered 10, 15, 50 and 78 kg, respectively)
- RfD: Reference dose (mg/kg/day) (it is 0.06 mg/kg/day for fluoride (EPA, 1992)).

RESULTS AND DISCUSSION

Fluoride accumulations in groundwater of Felent Stream Basin are given in Figure 2. Fluoride concentrations increased during the dry season at most stations, particularly at Ören (0.188 → 0.537 ppm), Köprüören (0.103 → 0.366 ppm), and Yoncalı (0.176 → 0.468 ppm). The highest dry season value was recorded at Ören, while the lowest wet season value was observed in Kütahya (0.069 ppm). Unlike the general trend, a slight decrease occurred at Enne during the dry period (0.294 → 0.273 ppm).

Fluoride plays a dual role in human health; while beneficial for dental integrity due to its strong affinity for tooth enamel, excessive intake can lead to significant adverse health outcomes (Taghipour et al., 2016; Tokatlı et al., 2022; 2023). A primary pathway for human fluoride exposure is drinking water, where optimal concentrations are instrumental in preventing dental caries and promoting overall well-being. Nevertheless, exceeding these beneficial levels can precipitate fluorosis, a widely recognized public health issue affecting dental health (Güner et al., 2016; Tokatlı and Güner, 2018; 2020; Jannat et al., 2022; Din et al., 2024). This study investigated fluoride concentrations in the groundwater of the Felent Stream Basin, finding levels that ranged from 0.069 to 0.537 ppm. Importantly, all examined stations exhibited fluoride concentrations well within the acceptable drinking water limit of 1.5 ppm, as defined by TS266 (2005), EC (2007), and WHO (2011).

Figure 3 presents fluoride exposure risk, showing all the average HQ values well below the acceptable threshold of 1, indicating a low overall risk. Consistent with previous findings, children (mean HQ: 0.27875) continue to exhibit the highest HQ values, underscoring their heightened sensitivity. Furthermore, dry season exposure conditions universally result in higher HQ values compared to wet season conditions, highlighting the significant influence of exposure pathways on risk assessment. Global research widely corroborates that children are particularly vulnerable to chronic health risks posed by fluoride consumption in drinking water (Gao et al., 2013; Narsimha et al., 2018; Dehghani et al., 2019; Qasemi et al., 2020; Tokatlı et al., 2022; 2023). This consistent finding underscores the critical need for meticulous assessment of fluoride exposure in pediatric populations. Supporting these prior observations, the present study likewise determined children to be the most at-risk demographic concerning health implications from fluoride exposure originating from the groundwater of the Felent Stream Basin.

Figure 2. Spatial – temporal fluoride accumulations of groundwater samples (ppm)

Figure 3. Spatio – temporal HQ values of different consumers

CONCLUSION

This study revealed significant seasonal fluctuations in groundwater fluoride concentrations within the Felent Stream Basin (Kütahya), with dry season levels (mean 0.404 mg/L) approximately double those of the wet season (mean 0.181 mg/L) due to reduced dilution and enhanced water-rock interaction. Health risk assessment consistently identified children as the most vulnerable group (HQ: 0.27875), with fluoride-related risks increasing for all age groups during the dry season. Despite overall levels being acceptable, these findings underscore the critical need for continuous groundwater monitoring, especially in dry periods, and targeted public health interventions to protect the dental health of children in the region.

ABSTRACT

Felent Stream, situated in Kütahya Province, is an important component of the Sakarya River Watershed in Türkiye. This study aimed (1) to investigate the spatial and temporal variations of fluoride concentrations in the surface waters of Felent Stream and (2) to evaluate the potential implications of these variations for the dental health of the local population. A total of seven sampling stations were established along the stream, and surface water samples were collected during both the wet and dry seasons of 2024. Fluoride concentrations were measured using a spectrophotometric method in accordance with standard analytical procedures. The results demonstrated distinct seasonal fluctuations in fluoride levels. The mean fluoride concentration recorded during the dry season was 0.749 mg/L, which was approximately 1.5 times higher than the mean value observed in the wet season (0.521 mg/L). The overall average across all samples was calculated as 0.635 mg/L. This increase during the dry period is likely related to reduced water flow and limited dilution, leading to greater accumulation of fluoride in the aquatic environment. According to the average HQ values, the highest potential risk was observed in children (0.59952), followed by teenagers (0.42319), adults (0.33909), and infants (0.08464). In addition, fluoride-related health risks increased across all age groups during the dry season.

Keywords: Felent Stream, Surface water, Fluoride accumulations

INTRODUCTION

Fluoride is an essential trace element that plays a vital role in maintaining dental health. While drinking water is considered the primary source of fluoride intake for humans, other exposure pathways include food, pharmaceuticals, and various industrial activities (Andezhath et al., 1993; Güner et al., 2016; Tokatlı and Güner, 2018; Onur and Tokatlı, 2020; Tokatlı et al., 2022; 2023). However, excessive fluoride intake can lead to adverse health effects, particularly dental and skeletal fluorosis.

In this context, health risk assessment practices have gained significant importance worldwide, especially in recent years. These methods provide a scientific framework for estimating both carcinogenic and non-carcinogenic risks associated with exposure to various environmental contaminants, including fluoride (Ustaoğlu and Aydın, 2020; Tokatlı and Ustaoğlu, 2020; Tokatlı and Varol, 2021a; 2021b; Varol and Tokatlı, 2022; Tokatlı et al., 2022; 2023). The application of such risk assessment approaches is particularly valuable in identifying vulnerable populations, informing regulatory actions, and ensuring the long-term safety of drinking water resources.

The Sakarya River Watershed stands as one of Türkiye's most significant and extensive riverine habitats, and the Felent Stream constitutes a crucial component of this vital system. Extending approximately 35 km in length with an average flow rate of 0.56 m³/s, the Felent Stream serves multiple purposes within the region. It is extensively utilized for industrial water supply and irrigation, playing a critical role in supporting local economic activities. However, it also functions as a receiving environment for wastewater discharges from numerous thermal tourism facilities located in the Yoncalı District, as well as domestic wastes originating from Kütahya Province (Solak et al., 2012; Çiçek et al., 2013; 2017). Further upstream, the Enne Dam Lake, a significant reservoir on the Felent Stream, contributes substantially to the region's water security by providing 6 hm³ of drinking water annually (Anonymous, 2022; <https://www.dsi.gov.tr/>). This dual role as both a valuable resource and a recipient of anthropogenic impacts underscores the ecological and socio-economic importance of the Felent Stream, warranting detailed investigation into its current status and management needs.

Given these multifaceted uses and potential impacts, this study specifically aimed (1) to investigate the spatial and temporal variations of fluoride concentrations in the surface waters of Felent Stream and (2) to evaluate the potential implications of these variations for the dental health of the local population.

MATERIALS AND METHODS

Surface Water Collection

Figure 1 illustrates the topographic configuration of the Sakarya River Watershed and the Felent Stream Basin, including the spatial distribution of the selected monitoring stations. Table 1 shows the coordinate information of sampling locations. Within the scope of this study, surface water samples were systematically collected from seven stations selected on the Felent Stream during both the wet and dry seasons of 2024.

Table 1. Coordinates of stations

Station	Zone of Basin Plains	Zone of Watershed	GPS – North	GPS – East
1. Station	Köprüören Plain	Upstream	39.52341	29.71731
2. Station	Köprüören Plain	Upstream	39.50703	29.76625
3. Station	Köprüören Plain	Upstream	39.48959	29.83703
4. Station	Köprüören Plain	Midstream	39.47417	29.86138
5. Station	Kütahya Plain	Midstream	39.46854	29.91585
6. Station	Kütahya Plain	Downstream	39.44115	29.98189
7. Station	Kütahya Plain	Downstream	39.45076	30.02648

Fluoride Analysis

Fluoride concentrations were quantified using a spectrophotometric technique, employing a Hach Lange DR 3900 spectrophotometer (wavelength range: 320–1100 nm) in conjunction with the Hach Lange LCK 323 cuvette test (measurement range: 0.1–2.5 mg/L) (<https://tr.hach.com/>).

Figure 1. Topographic map of Sakarya River Basin and selected sampling locations

Health Risk Assessment

In the present study, the population was stratified into four age groups based on physiological and behavioral characteristics: infants (<2 years), children (2–6 years), teenagers (6–16 years), and adults (>16 years). Daily fluoride exposure for each group was estimated using Equation 1. The non-carcinogenic health risk associated with fluoride intake was assessed using the Hazard Quotient (HQ), calculated according to Equation 2 (Yousefi et al., 2018). An HQ value below 1 indicates a negligible non-carcinogenic risk, whereas an HQ value above 1 suggests a potential health concern, with an increased likelihood of developing severe fluorosis.

$$EDI = \frac{Cf \times Cd}{Bw} \quad (1)$$

$$HQ = \frac{EDI}{RfD} \quad (2)$$

- EDI: Estimation of fluoride consumption – daily (mg/kg/day)
- C_f: Fluoride level in the investigated drinking water samples (mg/L)
- C_d: Mean daily water intake (L/day) (the mean water consumption rates in infants, children, teenagers and adults were 0.08, 0.85, 2 and 2.5 L/day, respectively)
- B_w: Body weight (kg) (body weights of investigated groups were considered 10, 15, 50 and 78 kg, respectively)
- RfD: Reference dose (mg/kg/day) (it is 0.06 mg/kg/day for fluoride (EPA, 1992)).

RESULTS AND DISCUSSION

Fluoride accumulations in surface water of Felent Stream are given in Figure 2. Fluoride concentrations reached their highest levels at Station 3 during both the wet (1.65 ppm) and dry (1.92 ppm) seasons. In general, an increase in fluoride levels was observed during the dry season, particularly at Stations 1, 2, 4, and 5. However, an exceptional decrease was noted at Station 7, where fluoride dropped from 0.342 ppm in the wet season to 0.040 ppm in the dry season.

Fluoride, while crucial for dental health due to its propensity for deposition in teeth, can also exert considerable adverse health effects on humans, contingent upon its concentration and exposure levels (Taghipour et al., 2016; Tokatlı et al., 2022; 2023). Drinking water serves as a primary source of fluoride exposure, and maintaining optimal fluoride levels in urban water supplies is known to have a preventive impact on overall body health, particularly in combating dental caries. Conversely, exposure to fluoride exceeding these optimal concentrations can lead to fluorosis, a significant concern for dental public health (Güner et al., 2016; Tokatlı and Güner, 2018; 2020; Jannat et al., 2022; Din et al., 2024). In the present study, fluoride concentrations in the surface water of Felent Stream varied from 0.040 to 1.920 ppm. Notably, fluoride levels at nearly all investigated stations (with the exception of Station 3) were found to be within the acceptable drinking water limit of 1.5 ppm, as stipulated by TS266 (2005), EC (2007), and WHO (2011).

Analysis of fluoride exposure risk, presented in Figure 3, indicates that while all the average HQ values are below the acceptable threshold of 1, children consistently exhibit the highest HQ values (mean 0.59952), suggesting increased susceptibility. Furthermore, dry season exposure conditions generally lead to higher HQ values across all age groups compared to wet season conditions. These findings underscore the critical importance of age-specific risk assessment and the distinct impact of exposure pathways in managing potential fluoride-related health risks. Numerous investigations globally have consistently highlighted that children face a significant chronic health risk from fluoride intake through drinking water (Gao et al., 2013; Narsimha et al., 2018; Dehghani et al., 2019; Qasemi et al., 2020; Tokatlı et al., 2022; 2023). These widespread findings underscore the heightened vulnerability of younger populations to fluoride-related health issues. In alignment with this established body of literature, our current research similarly identifies children as the age group most susceptible to health risks stemming from fluoride exposure via the surface water of Felent Stream.

Figure 2. Spatial – temporal fluoride accumulations of surface water samples (ppm)

Figure 3. Spatio – temporal HQ values of different consumers

CONCLUSIONS

This study revealed significant seasonal variations in fluoride concentrations within Felent Stream's surface waters, with dry season levels (mean 0.749 mg/L) being notably higher than wet season levels (mean 0.521 mg/L) due to reduced dilution. Health risk assessment confirmed that children face the highest potential risk (HQ: 0.59952) from fluoride exposure, followed by teenagers, adults, and infants, a finding consistent with global observations. Moreover, fluoride-related health risks increased across all age groups during the dry season, directly correlating with elevated concentrations. While overall fluoride levels generally remained acceptable, these findings underscore the critical importance of continuous monitoring and targeted public health strategies, especially for vulnerable populations during dry periods, to mitigate potential dental health impacts.

ABSTRACT

Greenhouse gas (GHG) emissions are among the primary causes of global warming and climate change. Gases such as carbon dioxide (CO₂), methane (CH₄), and nitrous oxides (N₂O) originate from human-induced activities, including fossil fuel consumption, industrial processes, agriculture, and deforestation. The accumulation of these gases in the atmosphere leads to rising temperatures, glacier melting, sea level rise, and an increase in extreme weather events.

This study explores various solutions to mitigate greenhouse gas emissions. Transitioning to renewable energy sources, such as solar, wind, and hydroelectric power, enhancing energy efficiency, promoting the widespread adoption of electric and hybrid vehicles in transportation, implementing sustainable agricultural practices, and initiating forest conservation projects are among the key strategies. Additionally, carbon capture and storage (CCS) technologies, alongside changes in individual consumption habits such as opting for low-carbon footprint products and increasing recycling efforts play a crucial role in reducing emissions.

Keywords: Greenhouse gas, global warming, industrial process, renewable energy

INTRODUCTION

Greenhouse gas (GHG) emissions represent one of the most critical environmental issues confronting the 21st century. This study investigates the ecological consequences associated with GHG emissions and evaluates a range of mitigation strategies aimed at reducing their impact. Particular focus is directed toward carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O), which constitute the primary anthropogenic greenhouse gases. The paper further discusses sustainable mitigation approaches, such as the deployment of renewable energy sources, enhancement of energy efficiency, implementation of carbon capture technologies, and large-scale reforestation efforts (Chen et al., 2023).

Greenhouse gases contribute to the retention of heat within the Earth's atmosphere, thereby exacerbating the greenhouse effect and elevating global temperatures. Although this

natural phenomenon is vital for sustaining life on Earth, anthropogenic emissions have significantly amplified its intensity, culminating in global warming and widespread climate disruption. Key drivers of GHG emissions include industrial processes, deforestation, and agricultural practices (Jensen et al., 2023). The resulting rise in global temperatures has led to an increase in the frequency and severity of heatwaves, as well as accelerated polar ice melt and thermal expansion of ocean waters, collectively contributing to sea level rise and heightened flooding risks (Aghakouchak et al., 2020).

Additionally, coastal marine ecosystems are increasingly threatened by anthropogenic activities, such as industrialization, agriculture, land-sea based aquaculture, and climate change. These pressures have led to coastal eutrophication, which is a major driver of macroalgal blooms (Smetacek and Zingone, 2013).

Macroalgal bloom events such as green and golden seaweed tides—induce profound shifts in both the physical and biogeochemical characteristics of the water column, thereby exerting considerable influence on greenhouse gas (GHG) emissions. Empirical evidence indicates that microalgal blooms can markedly decrease atmospheric carbon dioxide (CO₂) concentrations as a result of intensified photosynthetic activity. Concurrently, these events often stimulate the production of nitrous oxide (N₂O) and methane (CH₄), primarily through mechanisms involving the degradation of particulate organic matter (POM) and the emergence of hypoxic or anoxic conditions within marine systems (Cai et al., 2024).

The accelerating pace of climate change continues to pose serious threats to both human and ecological health (Romanello et al., 2022). In response to this escalating crisis, achieving the targets outlined in the Paris Climate Agreement and the Kigali Amendment to the Montreal Protocol necessitates a substantial and immediate reduction in global greenhouse gas emissions (Intergovernmental Panel on Climate Change, 2023).

According to estimates by the Food and Agriculture Organization of the United Nations (FAO), emissions from the agricultural sector account for approximately 30% of total global greenhouse gas (GHG) emissions. The predominant greenhouse gases emitted from agricultural soils include carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O) (Chataut et al., 2023).

In agricultural systems, both natural factors such as soil moisture, temperature, and pH and anthropogenic farming practices exert significant influence over the magnitude of GHG emissions. A wide body of research has investigated various strategies to mitigate these emissions. One promising approach involves the development and cultivation of crop varieties with enhanced capacities for carbon and nitrogen uptake. Such improvements can increase the efficiency of nutrient use, reduce dependence on synthetic fertilizers, and consequently decrease GHG emissions (Johansson et al., 2023).

Furthermore, optimizing fertilization practices including the timing, quantity, and type of fertilizers applied has been demonstrated to be an effective measure for controlling greenhouse gas emissions associated with agricultural activities (Li et al., 2023).

2. Environmental Impacts of Greenhouse Gas Emissions

2.1 Climate Change and Global Warming

The most direct and severe consequence of GHG emissions is global warming. Average global temperatures have increased significantly since the industrial revolution, resulting in more frequent and intense heatwaves, droughts, and wildfires.

Climate change refers to long-term shifts and alterations in temperature, precipitation patterns, wind, and other elements of the Earth's climate system. Global warming, on the other

hand, is the rise in the average surface temperature of the Earth due to increasing concentrations of greenhouse gases in the atmosphere (Koch et al., 2013).

2.2 Causes of Global Warming

The primary cause of global warming is human activity, particularly the burning of fossil fuels such as coal, oil, and natural gas. These activities release large amounts of greenhouse gases (especially carbon dioxide – CO₂, methane – CH₄, and nitrous oxide – N₂O) into the atmosphere. Other contributing factors include:

- Deforestation, which reduces the planet's capacity to absorb CO₂.
- Industrial processes that emit large quantities of GHGs.
- Agriculture, especially livestock farming which releases methane.
- Waste management practices that lead to the release of methane and other gases (Holgerson and Raymond, 2016).

2.3 Melting Ice Caps and Rising Sea Levels

The warming climate causes glaciers and polar ice caps to melt, contributing to rising sea levels. This threatens coastal ecosystems and human settlements, especially in low-lying countries and island nations.

One of the most visible and alarming consequences of global warming is the accelerated melting of polar ice caps and glaciers. This process directly contributes to rising sea levels, which pose serious threats to both natural ecosystems and human settlements, particularly in coastal and low-lying areas (Ren et al., 2020).

The treason of the melting of the ice caps can be described as; global temperatures rise. This means, Arctic sea ice is shrinking, especially during summer months. Land-based ice sheets and glaciers, such as those in Greenland and Antarctica, are losing mass rapidly. Melting land ice flows into oceans, increasing sea levels. Thermal Expansion means ocean temperatures increase, seawater expands. This thermal expansion accounts for nearly half of the observed sea level rise over the past century. Unlike sea ice, land-based ice adds new water to the ocean when it melts. The vast ice sheets in Greenland and Antarctica are currently the largest contributors to sea level rise from melting ice (Xie et al., 2021).

2.4 Current and Future Threats

Coastal Cities at Risk: Major urban areas like New York, Miami, Jakarta, Mumbai, and Istanbul face increased flooding and infrastructure damage. Saltwater intrusion can also contaminate freshwater supplies and damage agriculture.

Small Island Nations in Danger: Countries such as the Maldives, Tuvalu, and Kiribati are threatened with complete submersion if sea levels continue to rise, potentially creating the world's first "climate refugees."

Coastal Erosion and Habitat Loss: Rising seas accelerate erosion, submerge wetlands, and destroy mangroves and other critical coastal ecosystems.

Climate Migration: As coastal regions become uninhabitable, millions may be forced to migrate inland, leading to social, economic, and political challenges (Liu et al., 2021).

Scientific Projections: Over the 20th century, sea levels rose by approximately 15–20 centimeters (6–8 inches).

According to the Intergovernmental Panel on Climate Change (IPCC), sea levels are projected to rise by 0.6 to 1.1 meters (2 to 3.6 feet) by 2100 if greenhouse gas emissions continue at current levels.

2.5 Solutions and Adaptation Measures

Reducing greenhouse gas emissions can slow down global warming and ice melt. Coastal protection infrastructure, such as seawalls, flood barriers, and artificial islands, can help shield vulnerable areas. Climate adaptation policies must be developed, including strategic urban planning and relocation strategies for at-risk populations (Sheng et al., 2018).

2.6 Ocean Acidification

Excess CO₂ dissolves into oceans, lowering pH levels and disrupting marine ecosystems. Coral reefs, which are home to many marine species, are particularly vulnerable.

Ocean acidification refers to the ongoing decrease in the pH of the Earth's oceans, caused primarily by the uptake of carbon dioxide (CO₂) from the atmosphere. As anthropogenic CO₂ emissions have increased, a significant portion—approximately 30%—has been absorbed by the world's oceans. This process has altered the chemical composition of seawater, posing severe risks to marine biodiversity, ecosystems, and human societies dependent on oceanic resources (Alcaraz-Rocha et al., 2023).

This sequence results in the formation of carbonic acid (H₂CO₃), which dissociates to release hydrogen ions (H⁺), lowering the pH and increasing ocean acidity. As a consequence, the availability of carbonate ions (CO₃²⁻) which are essential for marine calcifying organisms to form shells and skeletons decreases.

2.7 Ecological Impacts

Coral Reef Degradation: Coral reefs are particularly sensitive to changes in pH. Ocean acidification weakens coral skeletons and inhibits reef growth, which in turn affects the vast array of marine life that depends on reef ecosystems for habitat and food (Hoegh-Guldberg et al., 2007).

Food Web Disruption: Many planktonic species form the foundation of marine food webs. The decline in their populations due to acidification can have cascading effects on higher trophic levels, including commercially important fish species (Yudhistira et al., 2023).

Impact on Marine Biodiversity and Fisheries: As marine ecosystems become destabilized, biodiversity loss is likely to accelerate. This endangers not only ecological balance but also the livelihoods of millions of people who rely on fisheries and aquaculture (Hollowed et al., 2013).

2.8 Socioeconomic Consequences

Food Security Risks: Communities that depend on shellfish and coral reef fisheries are particularly vulnerable to declining stocks and ecosystem collapse (Sovacool and Mukherje, 2011).

Economic Losses: The global seafood industry may face significant economic setbacks. Coral reef tourism, valued at billions of dollars annually, is also at risk (Kuznet, 2019).

3 Biodiversity Loss

Biodiversity loss refers to the decline or disappearance of biological diversity at the genetic, species, and ecosystem levels. As a result of anthropogenic climate change primarily driven by the emission of greenhouse gases (GHGs) natural habitats are increasingly subjected to environmental stressors that alter ecological balances, disrupt species interactions, and undermine ecosystem resilience. Among these stressors, rising temperatures, altered precipitation patterns, ocean acidification, and habitat degradation are particularly detrimental to biodiversity (Isbell et al., 2013).

3.1 Mechanisms of Biodiversity Loss Due to Climate Change

Habitat Alteration and Fragmentation: Shifts in temperature and precipitation can transform ecosystems, rendering them unsuitable for species that are highly specialized or geographically restricted. Alpine, polar, and coral reef ecosystems are especially vulnerable to these changes. Habitat fragmentation also limits species' ability to migrate in response to changing environmental conditions (Liu et al., 2023).

Consequences for Ecosystem Functioning: Biodiversity plays a critical role in ecosystem stability, productivity, and the provision of essential services such as pollination, water purification, carbon sequestration, and soil fertility. Loss of species richness and genetic diversity can reduce an ecosystem's capacity to respond to environmental changes and recover from disturbances, increasing the risk of ecological collapse (Tong et al., 2019).

4 Agricultural Disruption

Agricultural disruption refers to the adverse effects of climate change on crop production, livestock systems, soil health, and overall agricultural productivity. As global temperatures rise and climatic variability intensifies, agriculture the foundation of global food security and rural economies faces multifaceted challenges. These include altered growing seasons, increased frequency of extreme weather events, changing precipitation patterns, and the proliferation of pests and diseases. Such disruptions threaten the stability of food systems, particularly in regions already vulnerable to environmental and socio-economic stressors (Rees et al., 2014).

4.1 Climatic Stressors Impacting Agriculture

Temperature Increases: Higher average temperatures can accelerate crop maturation, leading to reduced yields. Heat stress also negatively affects livestock health, reproduction, and productivity. For many staple crops such as wheat, rice, and maize, there is a critical threshold beyond which yields decline substantially (Ma et al., 2020).

Extreme Weather Events: More frequent and severe heatwaves, storms, and frosts can cause sudden and severe damage to crops and infrastructure. These events not only reduce agricultural output but also increase production costs and risks for farmers (Wohlfart et al., 2008).

Increased Pest and Disease Incidence: Rising temperatures and humidity create favorable conditions for the spread of pests, fungi, and crop diseases, which were previously confined to specific geographic regions. This increases the vulnerability of food systems and requires greater dependence on chemical inputs (Méndez-Bautista et al., 2009).

Soil Degradation: Changes in temperature and precipitation, along with intensive agricultural practices, contribute to soil degradation, reducing fertility and the capacity to support sustainable farming (Cruz et al., 2020).

Regional Disparities and Vulnerabilities: Developing countries, particularly those in tropical and subtropical regions, are more severely affected due to limited adaptive capacity, high dependence on rain-fed agriculture, and constrained access to technology and infrastructure. Smallholder farmers, who represent a large portion of the global agricultural workforce, face increased livelihood insecurity and food scarcity as a result of climate-induced disruptions (Jia et al., 2018).

4.2 Adaptation and Resilience Strategies

Climate-Smart Agriculture (CSA): CSA practices aim to sustainably increase productivity, enhance resilience (adaptation), and reduce greenhouse gas emissions. This includes crop diversification, agroforestry, conservation agriculture, and efficient water management (nazim et al., 2025).

Technological Innovation: The development and dissemination of drought-resistant and heat-tolerant crop varieties, precision farming technologies, and early-warning systems can support adaptation (Lybbert and Sumne, 2012).

Policy and Institutional Support: Governments and international organizations must invest in agricultural research, rural infrastructure, extension services, and risk insurance schemes to support vulnerable farming communities.

Integrated Land and Water Management: Holistic approaches that conserve natural resources and promote sustainable land use are essential to long-term agricultural resilience.

DISCUSSION AND CONCLUSION

Greenhouse gas emissions pose a critical threat to the environment and to human societies. However, through coordinated global action and the implementation of innovative solutions, their negative impacts can be mitigated. Transitioning to a low-carbon future is not only possible but necessary to ensure the health of the planet for future generations. Multiple factors influence the impact of flooding on greenhouse gas emissions, including soil type, water source, and flood duration.

Agricultural disruption is a critical dimension of climate change with profound implications for global food systems, rural livelihoods, and economic stability. Urgent and coordinated adaptation strategies are necessary to ensure the sustainability and resilience of agriculture in a warming world.

Replacing fossil fuels with renewable sources such as solar, wind, and hydropower is one of the most effective ways to reduce GHG emissions. Improving the energy efficiency of buildings, transportation, and industrial processes can significantly cut emissions while reducing energy costs.

CCS technology captures CO₂ from power plants and industrial sources and stores it underground, preventing it from entering the atmosphere. Trees absorb CO₂ through photosynthesis. Large-scale tree planting can act as a natural carbon sink, helping offset emissions. Practices such as crop rotation, reduced tillage, and efficient fertilizer use can lower emissions from agricultural activities, especially methane and nitrous oxide.

Global cooperation through agreements like the Paris Accord is essential. Governments should implement carbon pricing, subsidies for clean energy, and stricter emission regulations.

In conclusion, the reduction of greenhouse gas emissions should not be confined solely to measures taken by governments and large corporations; rather, it should be recognized as a global responsibility in which individuals must also play an active role. While governments and businesses can make significant contributions by investing in renewable energy, enforcing strict environmental regulations, and implementing policies to limit carbon emissions, individuals can support this process by adopting eco-friendly habits in their daily lives. Key individual actions include conserving energy, opting for sustainable transportation methods, embracing recycling practices, making conscious consumption choices, and preferring products that minimize greenhouse gas emissions. In this context, the adoption of sustainable policies in both production and consumption, the promotion of innovative environmental technologies, and raising public awareness will be crucial in mitigating the devastating effects of climate change.

ABSTRACT

Plants and beneficial soil bacteria engage in dynamic and reciprocal interactions that influence plant development, nutrient acquisition, and stress resilience. Among these, plant growth-promoting bacteria (PGPB) have garnered considerable attention due to their ability to support plant health through a range of biochemical and physiological mechanisms. These bacteria produce a variety of bioactive compounds that enhance plant stress tolerance, improve nutrient availability, and offer protection against phytopathogens.

PGPB influence plant performance through both direct and indirect mechanisms. Direct pathways include the biosynthesis of phytohormones (such as indole-3-acetic acid), solubilization of essential nutrients like phosphate, zinc, and potassium, ammonia production, and atmospheric nitrogen fixation. Indirectly, they contribute by secreting siderophores, lytic enzymes, hydrogen cyanide, and antibiotics, which suppress harmful microorganisms and enhance plant immunity.

These functional traits position PGPB as valuable components in sustainable agriculture, especially for the development of bioformulants including biofertilizers, biopesticides, and biofungicides. Such alternatives reduce dependency on chemical inputs and contribute to environmentally responsible crop management. Nonetheless, despite the expanding repertoire of beneficial strains, the practical implementation of PGPB in agriculture remains challenging. Factors such as microbial survival, strain specificity, plant-microbiome compatibility, and fluctuating environmental conditions can influence their efficacy in field applications.

This review explores recent advances in understanding PGPB-mediated plant adaptations to abiotic and biotic stressors, with emphasis on molecular mechanisms, signaling pathways, and metabolite production. It also discusses formulation strategies and delivery systems designed to maximize their stability and performance. Ultimately, leveraging PGPB potential requires a deeper integration of microbiology, plant physiology, and environmental science to ensure their consistent and scalable use in sustainable agricultural systems.

Keywords: Plant Growth-Promoting Bacteria, stress tolerance, sustainable agriculture, biocontrol

INTRODUCTION

Through the release of bioactive chemical signals, bacteria and plants interact and communicate in a dynamic and ongoing co-evolutionary relationship. Both positive and negative interactions are possible (Wille et al., 2019). The plants gain from positive relationships because they help them acquire minerals, phytohormones, and other nutrients. By releasing a number of bioactive chemicals, these helpful bacterial species can also combat phytopathogens and help plants withstand a variety of stressful situations. Conversely, detrimental interactions are detrimental because infections infiltrate plant tissues, which causes the host plants to die (Dolatabadian, 2021; Adedayo et al., 2022). Utilizing these advantageous microbes can therefore help plants withstand stress that reduces their yield.

As part of the soil ecosystem, microorganisms have a major impact on the nitrogen cycle, soil fertility management, and plant diversity preservation. According to Zhou et al. (2020), a crucial area for important biological interactions between plants and microorganisms is the rhizosphere, a tiny area that surrounds the plant roots. Microorganisms such as bacteria, actinobacteria, fungus, algae, and protozoa aggressively compete for food and space in this productive area (Manghwar et al., 2023). Both the host and the microorganisms benefit from the ability of the plant growth promoting microorganism (PGPM) to live in and interact with plant roots; a population of rhizospheric bacteria and fungi may also serve as a home for other microbes (dos Lopes et al., 2021). The most prevalent of all the helpful microorganisms are bacteria, which are followed by fungus and actinobacteria (Poria et al., 2021). Through direct or indirect methods of nutrient absorption and assimilation, they have a beneficial effect on the plant (Kumari et al., 2018).

Food security is threatened by the world's population growth, which increases the need of fertilizers based on inorganic chemicals, which is bad for the environment and human health (Mitter et al., 2021). Because of the numerous environmental stressors that also contribute to low crop yields, organic farming that relies on microflora such as PGPM guarantees food availability while improving crop quality, productivity, and environmentally friendly farming practices (Jalal, et al., 2023). Therefore, by reducing the use of chemical fertilizers, crop production using PGPM provides sustainability and protects soil biodiversity (dos Lopes et al., 2021).

The majority of plant growth-promoting bacteria (PGPB) are proteobacteria. It includes genera like *Pantoea*, *Thiobacillus*, *Pseudomonas*, *Micrococcus*, *Rhodococcus*, *Azospirillum*, *Azotobacter*, *Acinetobacter*, *Acetobacter*, *Klebsiella*, *Enterobacter*, *Alcaligenes*, *Arthrobacter*, *Burkholderia*, *Azorhizobium*, *Achromobacter*, *Serratia*, *Bradyrhizobium*, *Flavobacterium*, *Mesorhizobium*, *Microrhizobium*, *Streptomyces*, *Bacillus*, *Azoarcus*, *Aeromonas*, *Azoarcus*, *Caulobacter*, *Chromobacterium*, *Delftia*, *Frankia*, *Flavobacterium*, *Gluconacetobacter*, *Paenibacillus*, *Rhizobium* and *Streptomyces* (Table 1).

Table 1. Plant growth promoting bacteria and their common host plant family (from Fanai et al., 2024).

Family	Plant	Plant growth-promoting bacteria
Fabaceae	<i>Phaseolus vulgaris</i>	<i>Rhizobium acidisoli</i> , <i>R. endophyticum</i> , <i>R. esperanzae</i> , <i>R. etli</i> , <i>R. hidalgoense</i> , <i>R. mesoamericanum</i> , <i>R. tropici</i> , <i>Acinetobacter</i> sp.
Poace	Rice, wheat, maize, soirghum, sugarcane	<i>Azospirillum</i> sp.
Asteraceae	Puticaria	<i>Bacillus cereus</i> , <i>Agrobacterium fabrum</i> , <i>Brevibacillus brevis</i> , <i>Bacillus subtilis</i> , <i>Paenibacillus</i> sp., <i>Acinetobacter radioresistant</i> , <i>Burkholderia</i> sp.
Solanaceae	<i>Artemisia annua</i>	<i>Brevibacillus</i> sp., <i>Bacillus</i> sp., <i>Pseudomonas</i> sp., <i>Azospirillum</i> sp., <i>Klebsiella</i> sp., <i>Enterobacter</i> sp., <i>Alcaligenes</i> sp., <i>Azotobacter</i> sp., <i>Streptomyces</i> sp., <i>Pantoea</i> sp., <i>Bacteroides</i> sp., <i>Proteobacteria</i> sp., <i>Radiobacter</i> sp., <i>Stenotrophomonas</i> sp.
Brassicaceae	<i>Brasica oleraceae</i>	<i>Pseudomonas</i> sp., <i>Enterobacter</i> sp., <i>Arthrobacter</i> sp., <i>Pantoea</i> sp.
Crasulaceae	<i>Echevari laui</i>	<i>Erwinia</i> sp., <i>Pantoea</i> sp.

In addition to helping plants tolerate a variety of biotic and abiotic stressors, the PGPB also promotes plant growth by promoting the solubility of various inorganic mineral nutrients, fixing nitrogen, releasing plant growth regulators, and producing a number of other biochemicals that either directly or indirectly increase plant productivity. Figure 1 shows the several ways that bacteria can promote plant growth.

Figure 1. Functions that plant growth-promoting bacteria provide. The impacts of both biotic (caused by living things) and abiotic (induced by environmental variables) stress on plants demonstrate how PGPB helps to lessen the effects of stress. Through processes including siderophores, lytic enzymes, HCN, antibiotics & nitrogen fixation, hormone synthesis, etc., PGPB improve plant development, nutrient absorption, and stress tolerance (from Fanai et al., 2024).

One possible approach to a sustainable future is the use of helpful microorganisms as bioinoculants in agricultural systems. As an effective, environmentally friendly, and productive fertilizer that could help meet the growing demand for food from the world's population, it is a good substitute for chemical fertilizers. They improved the soil microbiota and preserved soil fertility in addition to promoting plant growth.

ABIOTIC AND BIOTIC STRESS FACTORS

Continuously subjecting plants to biotic and abiotic stressors has a negative effect on their growth and development, which lowers yield and quality (Singh et al., 2021). With the help of a naturally occurring PGPB that increases resistance against different phytopathogens by generating biochemicals and improving soil fertility, plants subsequently develop particular kinds of defense mechanisms for stress response (Leontidou et al., 2020). Figure 2 shows the various stressors and bacterial stress tolerance systems.

Figure 2. Various stressors and bacteria that support plant growth react to provide plant growth promotion. The impacts of both biotic (caused by living things) and abiotic (induced by environmental variables) stress on plants demonstrate how PGPB helps to lessen the effects of stress. By means of processes like nitrogen fixation, hormone synthesis, and biocontrol, PGPB improve plant growth, nutrient absorption, and stress tolerance (from Fanai et al., 2024).

Drought stress is categorized into hydrological, socio-economic, meteorological, and agricultural types, each leading to soil moisture deficits and the accumulation of reactive oxygen species that damage plant structure and function (Ahluwalia et al., 2021). Traditional mitigation measures—such as biochar amendments, nanoparticle treatments, film farming, and drought-resistant cultivars—have shown only limited benefits in real agricultural systems (Fadiji et al., 2022). By contrast, plant growth-promoting bacteria (PGPB) enhance drought tolerance through improved water uptake, root architecture modification, and production of protective phytochemicals (Khan and Bano, 2019). For example, inoculation with *Bacillus pumilus* and *Pseudomonas putida* improved maize drought resilience and nutrient acquisition (Kálmán et al., 2024), while *Bacillus subtilis* and *Azospirillum brasilense* increased osmolyte synthesis to support wheat germination under water deficit (Ilyas et al., 2020). Strains such as *Pseudomonas lini* and *Serratia plymuthica* enhance soil aggregate stability, and *Bacillus albus* together with *Bacillus cereus* boost seed vigor, pigment concentration, and antioxidant activity, collectively strengthening photosynthetic efficiency and stress defenses (Zhang et al., 2020; Ashry et al., 2022; Saleem et al., 2021). Other notable drought-tolerant bacteria include *Achromobacter xylosoxidans*, *Pseudomonas aeruginosa*, *Lelliottia adecarboxylata*, *Enterobacter cloacae*, *Pseudomonas fluorescens* S3X, and *Staphylococcus sciuri* (Danish et al., 2020; Khalilpour et al., 2021).

A rise in average global temperatures poses a significant abiotic challenge for crop productivity (Desaint et al., 2021). Heat-tolerant microbes—including *Bacillus cereus*, *Serratia liquefaciens*, *Pseudomonas putida*, *P. fluorescens* (Mitra et al., 2021), *Burkholderia phytofirmans*, *Curvularia protuberata* (Rana et al., 2021), *Paraburkholderia phytofirmans*, and various *Bacillus* and *Pseudomonas* spp. (Ahmad et al., 2023)—mitigate thermal damage by modulating plant hormone levels (e.g., cytokinins, ACC deaminase) and activating antioxidant enzymes that control water uptake and induce heat-shock protein expression (Moumbock et al., 2021). Exogenous application of specific amino acids further alleviates heat-stress effects by enhancing stress-responsive pathways (Santos et al., 2022). Inoculation with *B. cereus* has been shown to boost overall biomass, chlorophyll content, and heat-shock protein accumulation (Khan et al., 2020b), while *Enterobacter* sp. SA187 increased wheat and *Arabidopsis* heat endurance, leading to higher grain yield, plant height, and seed weight. Moreover, *B. cereus* enhances carotenoid, protein, ascorbate peroxidase, chlorophyll, and superoxide dismutase levels (Bisht and Mishra, 2020), and strains such as *B. thuringiensis*, *B. subtilis*, *P. brassicacearum* (Ashraf et al., 2019), and *B. velenzensis* further demonstrate the promise of microbial inoculants for improving plant thermotolerance.

Soil salinization, driven by water scarcity and the accumulation of NaCl-rich compost from sewage and waste treatment, and the build-up of soluble ions—bicarbonate, magnesium, sodium, chloride, sulfate, carbonate, and calcium—alters soil composition, diminishes fertility, impairs germination, and disrupts chloroplast structure, leading to reduced pigment synthesis, ion toxicity, and osmotic imbalance (Ahmed et al., 2020; Krishnamoorthy et al., 2022). Salinity stress further reduces plant development, fruit yield, biomass, stomatal conductance, and water movement (Ansari et al., 2019). Plant growth-promoting bacteria counteract these adverse effects by inducing stress-responsive pathways that lower reactive oxygen species production, synthesizing Na⁺-binding exopolysaccharides, and producing phytohormones to enhance root growth and water uptake (Subramaniam et al., 2020). For instance, *Bacillus amyloliquefaciens* GB03 releases volatile organic compounds that boost stress mitigation sixfold (Cappellari et al., 2020). Additionally, halotolerant strains of *Streptomyces*, *Aneurinibacillus aneurinilyticus*, *Paenibacillus* spp., *Pseudomonas azotoformans*, and other genera such as *Bacillus*, *Enterobacter*, *Klebsiella*, *Agrobacterium*, and *Ochrobactrum* can tolerate NaCl up to 150 g/L, highlighting their promise in reclaiming saline soils (Liu et al., 2021).

Plant growth-promoting microbes (PGPM) suppress biotic stresses from pathogenic fungi, bacteria, nematodes, insects, and weeds by activating systemic acquired resistance (SAR) and induced systemic resistance (ISR). SAR arises when PGPM directly inhibit pathogens, whereas ISR is triggered by bacterial elicitors such as volatile organic compounds (VOCs), microbe-associated molecular patterns (MAMPs), and bioactive secondary metabolites (Dubey et al., 2020). These microbes employ lytic enzymes, antibiotics, and VOCs for direct antagonism and enhance plant defenses indirectly through nitrogen fixation, siderophore production, phosphate solubilization, and phytohormone signaling (Migunova and Sasanelli, 2021). For instance, *Pasteuria penetrans* and *Brevibacillus laterosporus* secrete proteases that inhibit *Heterodera glycines* (Mohan et al., 2020), while *Bacillus megaterium* combats *Meloidogyne graminicola* similarly. Strains like *Pseudomonas aeruginosa*, *P. cepacia*, and *P. fluorescens* exhibit broad-spectrum antimicrobial and anthelmintic activities (Bhavva and Geetha, 2021), and *Bacillus subtilis* and *B. pumilus* produce chitinases and antifungal VOCs that disrupt nematode chitin synthesis. *Bacillus amyloliquefaciens* FZB42 and *Arthrobacter nicotianae* release bacteriocins and VOCs that inhibit *Meloidogyne* spp. By colonizing the rhizosphere and producing siderophores, phytohormones, and antibiotics, PGPM also inhibit soil-borne fungi, solubilize phosphate, and promote plant growth via indole-3-acetic acid synthesis. These combined actions outcompete pathogens for nutrients and induce ISR against

bacterial genera—such as *Erwinia*, *Pectobacterium*, *Pantoea*, and *Xanthomonas*—that cause wilts, blights, galls, and root rots (Nazari and Smith, 2020; Nabila and Kasiamdari, 2021).

Table 2. Overview of Plant Growth-Promoting Rhizobacteria functions (from Priyanka et al., 2020)

Function of PGPR	Description	PGPR strain
Nitrogen fixation	Conversion of free atmospheric nitrogen into oxide form that can be used	<i>Enterobacter</i> , <i>Klebsiella</i> , <i>Burkholderia</i> , and <i>Stenotrophomona</i>
Phosphate solubilization	Conversion of insoluble phosphate into the soluble form absorbed by the plants	<i>Achromobacter</i> , <i>Agrobacterium</i> , <i>Bacillus</i> , <i>Enterobacter</i> , <i>Erwinia</i> , <i>Escherichia</i> , <i>Flavobacterium</i> , <i>Mycobacterium</i> , <i>Pseudomonas</i> and <i>Serratia</i>
Potassium solubilization	Conversion of potassium in the useful form	<i>Acidithiobacillus ferrooxidans</i> , <i>Bacillus edaphicus</i> , <i>Bacillus mucilaginosus</i> , <i>Burkholderia</i> , <i>Paenibacillus</i> sp. and <i>Pseudomonas</i>
Production of siderophore	Enhancing the source of iron in the soil that can be absorbed by the plants	<i>Aeromonas</i> , <i>Azadirachta</i> , <i>Azotobacter</i> , <i>Bacillus</i> , <i>Burkholderia</i> , <i>Pseudomonas</i> , <i>Rhizobium</i> , <i>Serratia</i> and <i>Streptomyces</i> sp.
Phytohormone production	Production of phytohormones such as auxin, cytokinins, gibberellic acid and ethylene	<i>Azotobactersp.</i> , <i>Rhizobium</i> sp., <i>Pantoea agglomerans</i> , <i>Rhodospirillum rubrum</i> , <i>Pseudomonas fluorescens</i> , <i>Bacillus subtilis</i> and <i>Paenibacillus</i> sp.

DIRECT AND INDIRECT MECHANISMS OF PGPB IN ENHANCING PLANT PERFORMANCE

Indirect mechanisms

Siderophore production: Bacteria secrete ferric-specific ligands (hydroxamates, phenolates, carboxylates) to solubilize iron for themselves and host plants, enhancing root colonization and outcompeting pathogens; common producers include *Bacillus*, *Chryseobacterium*, *Phyllobacterium*, and *Pseudomonas* spp. (Bhatt et al., 2019).

Protease secretion: Microbial proteases (alkaline, acidic, neutral)—notably from *Bacillus* spp.—hydrolyze pathogen proteins and generate antifungal metabolites (e.g., serine proteases, subtilisins), serving as an indirect plant defense; activity is screened on skim-milk agar by clear halo formation (Castaldi et al., 2021).

Catalase activity: Catalase-positive strains (e.g., *Bacillus marinus*, *B. sphaericus*, *Staphylococcus aureus*) detoxify H₂O₂ at root interfaces, mitigating oxidative damage under stress; detected by bubble formation in 3% H₂O₂ (Talaiekhazani, 2022).

Amylase production: Alpha-amylases from endophytes like *Bacillus amyloliquefaciens* and *B. licheniformis* degrade pathogen cell walls and contribute to industrial applications (detergents, stain removal); screened on starch agar via iodine-stained halos (Ismail et al., 2021).

Urease activity: Ureolytic bacteria hydrolyze urea into plant-available ammonium and nitrates, supporting nitrogen nutrition and biomineralization (soil enrichment, concrete repair); measured by pH-dependent color change in urea broth (Cui et al., 2022).

Hydrogen cyanide (HCN) release: Rhizobacteria (mostly *Pseudomonas* and *Bacillus* spp.) emit HCN to inhibit fungi, nematodes, insects, and weeds without harming the host plant; detected via alkaline-picrate colorimetric assay (Alemu, 2016).

Table 3. Mechanisms and functions of PGPB (*adapted from Olanrewaju et al. (2017) and Fanai et al. (2024)*)

Mechanism	Category	Primary Function	Reference
Indole-3-acetic acid (IAA)	Direct	Stimulates root initiation, cell division, lateral root formation	Olanrewaju et al. (2017)
ACC deaminase activity	Direct	Degrades precursor of ethylene; alleviates abiotic-stress inhibition	Olanrewaju et al. (2017)
Cytokinin production	Direct	Promotes shoot growth, delays leaf senescence	Fanai et al. (2024)
Nitrogen fixation	Direct	Converts atmospheric N ₂ into bioavailable NH ₄ ⁺	Fanai et al. (2024)
Phosphate solubilization	Direct	Releases organic acids to convert insoluble P into plant-available forms	Fanai et al. (2024)
Siderophore production	Indirect	Sequesters Fe ³⁺ , suppresses pathogen growth, improves iron nutrition	Olanrewaju et al. (2017)
Lytic enzyme secretion	Indirect	Produces chitinases/proteases to degrade fungal and nematode walls	Olanrewaju et al. (2017)
Hydrogen cyanide (HCN) emission	Indirect	Volatile compound that inhibits soil-borne pathogens and weeds	Olanrewaju et al. (2017)
Antibiotic metabolite release	Indirect	Synthesizes antimicrobial compounds against bacteria and fungi	Olanrewaju et al. (2017)
Induced systemic resistance (ISR)	Indirect	Elicits plant defense pathways via MAMPs and VOCs	Fanai et al. (2024)

Direct mechanisms

Phytohormone production: Plant growth-promoting bacteria (PGPB) synthesize cytokinins, gibberellins, and especially indole-3-acetic acid (IAA), which regulate cell division, root initiation, and stress responses. Strains such as *Paenibacillus polymyxa*, *Rhizobium leguminosarum*, *Pseudomonas fluorescens* produce cytokinins (Mekureyaw et al., 2022), while *Bacillus pumilus* and *B. licheniformis* generate multiple gibberellins (Gutiérrez-Mañero et al., 2001). IAA producers, including *Azospirillum*, *Arthrobacter*, *Bradyrhizobium*, *Pantoea*, *Rahnella*, and *Enterobacter*, enhance root elongation and nutrient uptake (Rehman et al., 2020).

Phosphate solubilization: PSB release organic acids (citric, gluconic) that chelate cations and convert insoluble phosphates (tricalcium, rock phosphate) into bioavailable forms. Key taxa include *Pseudomonas putida*, *Azospirillum lipoferum*, *Bacillus firmus*, *B. polymyxa*, *Serratia marcescens*, and *Arthrobacter aureofaciens*. PSB inoculation boosts phosphorus

availability and activates stress-responsive genes in crops like potato and sugarcane (Lin et al., 2023).

Ammonia production: Ammoniogenic PGPB such as *Pseudomonas putida*, *Klebsiella* spp., and *Enterobacter asburiae* generate NH_3 , raising soil pH to suppress pathogens and supply inorganic nitrogen, which enhances root/shoot growth and biomass (Gohil et al., 2022).

Nitrogen fixation: Symbiotic genera (*Bradyrhizobium*, *Mesorhizobium*, *Sinorhizobium*, *Azorhizobium*, *Neorhizobium*) and free-living diazotrophs (*Azotobacter*, *Azospirillum*, *Burkholderia*, *Pseudomonas*, cyanobacteria) convert atmospheric N_2 into plant-available forms, supporting growth and yield (Basile and Lepek, 2021). Microbial consortia of *B. subtilis* and *A. brasilense* enhance root/shoot development, gas exchange, and grain yield in wheat, while co-inoculation of *Bradyrhizobium* and *Bacillus* improves nodulation and *Vigna unguiculata* productivity (Galindo et al., 2024; Gaspareto et al., 2023).

Zinc solubilization: Zinc is a vital enzyme co-factor, with optimal plant tissue levels at 30–100 $\text{mg}\cdot\text{kg}^{-1}$; deficiency impairs growth and causes necrotic lesions. Zinc-solubilizing

bacteria secrete organic acids and iron-chelating enzymes to lower rhizosphere pH and release Zn^{2+} (Eshaghi et al., 2019). Key taxa include *Pseudomonas aeruginosa*, *Gluconacetobacter diazotrophicus*, *P. striata*, *P. fluorescens*, *Burkholderia cenocepacia*, *Serratia liquefaciens*, *S. marcescens*, *Bacillus thuringiensis*, *B. aryabhattai*, *B. subtilis*, *Thiobacillus thiooxidans*, and cyanobacteria. *Rhizobium*, *Pseudomonas*, and *Bacillus* spp. enhance Zn translocation and grain biofortification, improving wheat quality via exopolysaccharide and siderophore production (Jalal et al., 2024). Co-inoculation of *B. subtilis* or *P. fluorescens* with foliar ZnO further boosts maize chlorophyll, amino acids, glutelin, and prolamin content. Bacterial Zn nanoparticles inhibit biofilm formation in pathogens and augment human oral microbiome antimicrobial activity (Lallo da Silva et al., 2019).

Figure 3. Overview of the main mechanisms used by PGPB to improve plant growth (from Vuolo et al., 2022)

Potassium solubilization: Although abundant in soils, K often exists in insoluble forms; PGPB release organic acids (citric, oxalic, tartaric) to chelate and solubilize K⁺, facilitating uptake (Olaniyan et al., 2022). Potassium activates over 60 plant enzymes, regulates stomatal dynamics, enhances disease resistance, fiber strength, and produce quality, and mitigates water-stress sensitivity (Rawat et al., 2022). Notable K-solubilizers include *Acidithiobacillus*, *Burkholderia*, *Pseudomonas* spp., *Bacillus megaterium*, *Arthrobacter*, *Pantoea ananatis*, *Rahnella aquatilis*, *Enterobacter* sp., *Bacillus/Paenibacillus mucilaginosus*, *Bacillus licheniformis*, *P. azotoformans*, *B. edaphicus*, and *Pseudomonas putida* (Bakhshandeh et al., 2017).

CONCLUSION

Plant growth-promoting bacteria represent a cornerstone of sustainable agriculture by naturally supplying key metabolites—phytohormones, siderophores, lytic enzymes, hydrogen cyanide, and ammonia—and by solubilizing essential nutrients (P, Zn, K) or fixing atmospheric nitrogen. Their multifaceted modes of action not only enhance crop yield and quality under both biotic and abiotic stresses but also reduce reliance on synthetic agrochemicals, thereby protecting soil health and the broader environment.

To translate this promise into practice, future work must prioritize the development and field-ready formulation of robust biofertilizers and biocontrol agents tailored to specific crops and stress conditions. Equally critical is the systematic evaluation of PGPB–host compatibility to safeguard beneficial traits during root colonization, as well as the design of microbial consortia whose members coexist synergistically without compromising individual functionality. Addressing these challenges will pave the way for precision applications of PGPB, driving both productivity gains and ecological resilience in modern farming.

ABSTRACT

Herbicides, long heralded as precise tools in agricultural management, leave behind echoes that reverberate through the most intimate layers of ecological networks. This study explores how herbicidal interventions—especially those involving compounds like glyphosate—silently alter microbial communities that anchor essential ecosystem functions. These non-target effects begin at the microscopic scale, where shifts in soil microbiome composition interrupt vital processes such as nutrient cycling, rhizosphere signaling, and plant–soil feedback mechanisms.

Framed through a microbiome-centric lens, we present a synthesis of recent studies alongside conceptual models illustrating how herbicide residues serve not only as chemical stressors, but as agents that restructure the metabolic dialogues among microbes and their hosts. Alterations in microbial diversity and function affect plant vitality, reduce resilience to biotic and abiotic stresses, and cascade upward to influence animal performance, herbivory dynamics, and pollination success. As herbicides disrupt these finely tuned interdependencies, we observe potential tipping points that may reshape ecosystem trajectories and even influence microbial and host evolution.

More than collateral damage, microbial responses to herbicidal exposure represent a silent rebellion—one with the power to mediate or magnify ecological instability. We advocate for integrative strategies that acknowledge microbiome health as a central criterion in agrochemical risk assessments. Understanding these subterranean symphonies is essential for mitigating the long-term consequences of anthropogenic disturbance and for crafting sustainable, microbe-conscious stewardship of ecosystems.

Keywords: microbiome, herbicides, soil microbial networks, environmental resilience, agrochemical impact, microbe-mediated risk

INTRODUCTION

Herbicides have revolutionized modern agriculture by enabling targeted and efficient weed control, contributing significantly to crop productivity and food security. Among these, **glyphosate** stands as one of the most extensively used broad-spectrum herbicides worldwide due to its effectiveness and non-selective inhibition of the *5-enolpyruvylshikimate-3-phosphate synthase* (EPSPS) enzyme in the shikimate pathway (Duke and Powles, 2008). However, while glyphosate's primary mode of action is aimed at plants, this same biochemical pathway is present in many soil microorganisms, raising growing concerns about its unintended effects on non-target species (van Bruggen et al., 2018).

Soil microbial communities, particularly those inhabiting the **rhizosphere**, play a pivotal role in maintaining ecosystem functions. These communities mediate **nutrient cycling**, **organic matter decomposition**, and intricate **plant–microbe interactions** that influence plant growth, health, and resistance to environmental stressors (Berg et al., 2020). Disturbances to microbial composition and diversity—whether through direct toxicity or altered plant exudation patterns—can ripple through the entire ecosystem. Emerging evidence suggests that herbicide residues can suppress **mycorrhizal colonization**, shift **bacterial community structures**, and increase plant susceptibility to **soil-borne pathogens** (Zaller et al., 2014; Newman et al., 2016; Johal and Huber, 2009).

Figure 1. The intricate connections between soil biodiversity and plants. a These interactions are influenced, including chemical, physical, and biological variability. b In a stable ecosystem with no or low human disturbances, plants can effectively recruit their microbial communities, primarily facilitated through rhizosphere exudation and selection processes. This plant-soil biodiversity interactions catalyze multiple ecosystem processes such as enhanced enzyme activity, solubilization, nitrogen fixation, and disease suppressiveness. However, land degradation and ongoing climate changes disrupt these interactions, leading to an increased negative correlation among taxa. c As a result, plants become more vulnerable to harmful and opportunistic agents like insects and pathogens (from Pedrinho et al., 2024).

Importantly, these microbial alterations are not merely short-term or incidental. Herbicides may induce long-term **restructuring of microbial networks**, with implications for microbial evolution, functional redundancy, and overall soil resilience (Timmis et al., 2019). Furthermore, **chronic exposure** to glyphosate and similar compounds may drive microbial **adaptation or resistance**, potentially reducing the soil's capacity to buffer abiotic stressors such as drought or nutrient depletion (Schlatter et al., 2017).

Given the central role of the microbiome in **agroecosystem stability**, there is an urgent need to reconsider how herbicides are evaluated in terms of ecological risk. Traditional assessments focusing solely on crop yield or visible phytotoxicity fall short of capturing the subtle but profound consequences on **microbial health**. Integrating a **microbiome-centric perspective** into agrochemical regulation offers a more holistic understanding of ecosystem sustainability and resilience (Mitter et al., 2019).

This paper synthesizes recent findings on the impact of herbicides—especially glyphosate—on soil microbial communities. It aims to elucidate the biochemical, ecological, and evolutionary consequences of microbial disruption, and to advocate for frameworks that prioritize **microbial integrity** as a cornerstone of sustainable agriculture.

HERBICIDES AND THEIR LEGACY

Herbicides have revolutionized modern agriculture by enabling efficient weed control, reducing labor costs, and increasing crop yields. Since the introduction of synthetic herbicides like 2,4-D in the 1940s, over 270 active ingredients have been commercialized, shaping global farming practices and food systems (Mesnage et al, 2021; U.S. EPA, 2004). However, their legacy is complex—marked by ecological disruption, resistance evolution, and persistent residues in soil and water. Herbicides have played a central role in modern agricultural intensification, with compounds like **glyphosate**, **atrazine**, and **2,4-D** becoming dominant tools in weed control (Duke and Powles, 2008). Glyphosate, in particular, has been praised for its broad-spectrum action and post-emergent use. However, its primary target—the *shikimate pathway*, absent in animals but present in most plants and microbes—raises significant concerns about **non-target effects** on microbial communities (van Bruggen et al., 2018). While herbicides were initially believed to degrade rapidly in soil, increasing evidence shows that **residues persist** and interact with complex biotic and abiotic soil components, affecting ecosystem function far beyond weed suppression (Silva et al., 2019). Herbicides such as glyphosate, atrazine, and dicamba have become staples in conventional farming due to their broad-spectrum activity and compatibility with genetically modified (GM) crops (Parven et al., 2024). Systemic and pre-emergence herbicides offer targeted control, reducing the need for repeated applications and mechanical weeding.

Despite their utility, herbicides pose significant risks, as **soil degradation** (long-term use alters microbial communities, reduces biodiversity, and impairs nutrient cycling), **water contamination** (runoff and leaching introduce herbicide residues into aquatic ecosystems, affecting non-target organisms like amphibians, fish, and invertebrates) and **resistance development** (overuse has led to herbicide-resistant weed populations, complicating management and increasing chemical dependency (Mesnage and Antoniou, 2017).

Figure 2. Possible interference of glyphosate with microbial communities in the rhizosphere and endosphere (from Sibalekile et al., 2025).

THE RHIZOSPHERE MICROBIOME: KEYSTONE OF SOIL HEALTH

The **rhizosphere microbiome**—microorganisms that inhabit the narrow zone surrounding plant roots—plays a foundational role in **nutrient cycling, stress response, and plant immunity** (Berg et al., 2020).

The specific functions of soil microbes can be divided into seven major groups (Berendsen et al., 2012; Cheng et al., 2022; Kumar et al., 2022):

- **Decomposition:** Microbes—bacteria and fungi—break down organic matter such as crop residues, insect carcasses, animal manure, and other organic materials in the soil. Microbes secrete enzymes that help break down complex organic compounds into simpler forms, releasing nutrients that plants can use. Microbes contribute to humification as they break down organic compounds. Humification produces stable, mature organic compounds that increase the organic matter content of the soil. This offers additional benefits to crops, such as increased water-holding capacity, nutrient retention, and carbon sequestration.
- **Nutrient cycling:** Microbes are involved in the circulation of essential nutrients in the soil. They can “unlock” nutrients that are locked up in forms inaccessible to the plant and therefore promote the availability of nutrients for plant absorption. Nitrogen fixation (mineralization) is one example of how many beneficial soil microbes convert organic nutrients into inorganic forms that can be absorbed by plants. Soil microbes also unlock nutrients from inorganic “bound” forms.
- **Soil structure and aggregation:** Certain bacteria and fungi produce sticky substances such as polysaccharides that bind soil particles together, forming aggregates. Soil

aggregates improve soil structure, porosity, and water-holding capacity, allowing for better root penetration and aeration.

- **Disease suppression:** Certain beneficial bacteria and fungi called biocontrol agents can suppress soil-borne pathogens and pests. Biocontrol agents suppress pathogens and pests through a variety of processes, including: producing antimicrobial compounds, consuming or parasitizing pests and pathogens, or outcompete pathogens for soil niches. The term "disease-suppressing soils" is often used to refer to fields that experience little or no impact from soil-borne diseases, even when the diseases are widespread throughout the surrounding region or minimal crop protection products are used. Microbial biocontrol agents are known to play a key role in the ability of disease-suppressing soils to mitigate the impacts of pathogens.
- **Phytohormone Production:** Some soil microbes can produce plant hormones in the soil, many of which are called "plant growth regulators" or PGRs. Hormones such as auxin, cytokinin, and gibberellin are known to support plant growth, yield, and stress tolerance when applied as foliar products. However, their routine application can be very expensive. Microbial hormone producers in the soil can also offer these benefits and have been found to support crop resistance to stressors such as drought and activate plant defense systems to ward off pathogens.
- **Symbiotic relationships:** Many plants form beneficial symbiotic relationships with soil microbes. Mycorrhizal fungi form associations with plant roots, extending their reach for water and nutrients in exchange for microbial "food" in the form of carbon produced by the plant through photosynthesis. Mutually beneficial bacteria, known as endophytes, live within plant tissues and promote plant growth by performing beneficial processes such as nitrogen fixation and carbon uptake through root exudates. This symbiotic relationship improves plant nutrient uptake, overall plant and soil health, and the efficiency of agricultural systems. However, common agricultural practices can disrupt these relationships, leading to a decline in beneficial microbes and increased dependence on agricultural inputs.
- **Salinity regulation:** Some microbes have adapted to survive in saline environments and possess mechanisms to tolerate high salt concentrations. They can actively colonize and thrive in saline soils where other organisms struggle. Salt exclusion is when certain microbes have mechanisms to exclude salts from their cells or actively limit their uptake. By excluding salts, microbes can ensure proper cellular function and growth in high salinity conditions. Salt metabolism is when certain microbes possess enzymes that can metabolize or break down specific types of salts. They can convert salts into less harmful forms or compounds that other organisms can use.

In short, balancing microbiome disruptions with practices that support plant-microbe symbiosis, such as cover crops and conservative tillage, is key to optimizing soil health processes and harnessing the benefits of soil microbes.

These microbial consortia are sensitive to external chemical inputs and serve as early indicators of soil disturbance (Kurenbach et al., 2021; Yang et al., 2023; El-Helow et al., 2024). Herbicides can alter:

- **Microbial richness and evenness**
- **Community composition** (e.g., shifts from *Proteobacteria* to *Actinobacteria*)
- **Enzyme activity**, such as dehydrogenase and phosphatase
- **Plant-microbe communication**, such as root exudate signaling

Soil microbial consortia—interactive communities of bacteria, fungi, archaea, and protists—are highly sensitive to herbicide exposure. Although herbicides are designed to target weeds, their biochemical specificity often extends to non-target organisms, leading to unintended disruptions in soil microbial dynamics. Also, herbicides can disrupt microbial communities by following mechanisms (Kurenbach et al., 2021; Yang et al., 2023; El-Helow et al., 2024):

- **Enzyme inhibition:** Common herbicides like glyphosate inhibit the shikimate pathway, which is present in bacteria and fungi. This hampers the synthesis of vital aromatic amino acids such as tryptophan, tyrosine, and phenylalanine, affecting microbial growth and metabolism.
- **Loss of microbial diversity:** Herbicide exposure can shift community composition by reducing beneficial groups like nitrogen-fixing bacteria, phosphate-solubilizers, and symbiotic fungi. This undermines key soil functions like nutrient cycling and plant-microbe interactions.
- **Metabolic shifts and functional decline:** While some microbes adapt to herbicides, this often comes with altered metabolic activity or reduced efficiency in organic matter decomposition and other soil biochemical processes.
- **Antibiotic resistance proliferation:** Studies show that prolonged herbicide use can increase the abundance of antibiotic resistance genes (ARGs) and mobile genetic elements (MGEs), potentially facilitating the spread of resistant pathogens through horizontal gene transfer.

ADAPTIVE RESPONSES AND MICROBIAL RESISTANCE

Repeated herbicide exposure can drive **microbial adaptation**, including **degradation capability evolution** (e.g., *Pseudomonas* acquiring glyphosate degradation genes), **shift toward resistant or resilient taxa or horizontal gene transfer** of resistance traits. While such adaptations may improve degradation efficiency, they may also alter **microbial network interactions**, affecting ecological balance (Rousidou et al., 2013). Microbial shifts may feed back into **plant susceptibility**, nutrient cycles, and carbon dynamics, especially under climate stress.

Microbes adapt to herbicides through several strategies, such as **efflux pump activation**, **membrane modifications** (like changes in membrane permeability help microbes limit herbicide uptake and increase resistance to antibiotics), **stress response pathways** (e.g. herbicide exposure triggers oxidative stress, DNA damage, and SOS responses, which can lead to mutagenesis and horizontal gene transfer) and **cross-resistance evolution** (mutations that confer herbicide tolerance may also increase resistance to antibiotics, especially when stress pathways overlap) (Liao et al., 2021; Hill, 2017). These adaptive responses have cascading effects **soil microbiome disruption, antimicrobial resistance and food chain contamination, like** residual herbicides and resistant microbes can enter crops and livestock, posing risks to human health (Daram et al., 2021; Paul and Mandal, 2019).

HERBICIDE EFFECTS ON ECOSYSTEM-LEVEL PROCESSES

While the rhizosphere is a well-studied hotspot of microbial activity, recent research reveals that microbial alterations extend far beyond root zones, influencing **macroecological processes** such as nutrient cycling, carbon sequestration, biodiversity patterns, and ecosystem resilience. These changes are not confined to local soil patches—they ripple across landscapes and biomes, shaping ecological trajectories at multiple scales (Wang and Zou, 2024; Mohanram and Kumar, 2019). Microbial communities in bulk soil, litter layers, and aquatic interfaces

respond dynamically to environmental perturbations, including herbicide exposure, land-use change, and climate variability. These shifts can **alter biogeochemical cycles, modulate greenhouse gas emissions** and **influence plant community assembly** (Pantigoso et al, 2022; Ruuskanen et al., 2022).

Microbial alterations often involve **cross-kingdom interactions**, such as fungal networks facilitating bacterial dispersal or protists regulating microbial grazing. These interactions contribute to **soil organic matter formation, trophic cascades** and to **habitat connectivity**.

Beyond the rhizosphere, microbial alterations influence **macroecological processes, such as carbon sequestration** via changes in microbial respiration, **nitrogen and phosphorus cycling and soil aggregation and erosion resistance**. Several studies report that herbicide-induced microbial imbalance can decrease **soil organic matter**, reduce **greenhouse gas buffering capacity**, and lower **crop resilience to drought and pests** (Ghimire et al., 2020). These indirect impacts challenge the long-held belief in herbicide neutrality toward ecosystem services.

Figure 3. Ecosystem model showing cascading impacts of microbial disruption—soil health, plant health, insect interactions, and ecosystem services.

Herbicides have long been regarded as indispensable tools in modern agriculture—cost-effective, targeted, and efficient. Yet, their ecological footprint reaches far beyond weed suppression. Current herbicide risk assessment frameworks primarily focus on chemical persistence, toxicity to plants and animals, and residue levels in food and water. What remains largely overlooked is the impact of herbicides on the **soil microbiome**, a critical engine of nutrient cycling, plant health, and ecosystem stability (Sweeney et al., 2025; Kodikara et al., 2022).

Soil microbes—especially those in the rhizosphere—play foundational roles in maintaining agroecological functions. However, these organisms are almost entirely absent from conventional toxicological testing. Risk assessments typically rely on short-term, single-organism studies that fail to reflect the complexity and dynamism of microbial communities, which are deeply intertwined with numerous ecosystem services (Zhao et al., 2025; Wend et al., 2024).

An additional blind spot lies in **microbial genetic mobility**, where herbicide-induced stress can activate antibiotic resistance genes (ARGs) and mobile genetic elements (MGEs). This not only jeopardizes soil health but also raises concerns about public safety via the

potential horizontal transfer of resistance traits to pathogenic microbes (EFSA, 2023; Liao et al., 2021).

Table 1. Gaps in Herbicide Risk Assessment.

Assessment Domain	Current Gaps
Soil Health	Focused mainly on chemical residues and physical structure
Non-target Effects	Limited consideration of microbial collateral damage
Temporal Dynamics	Assessed via static endpoints (e.g., residue half-life)
Bioindicator Integration	Rarely utilizes microbial indicators
Interaction Effects	Ignores chemical synergy or antagonism with microbial networks
Resistance Development	Focused on weed resistance only
Ecosystem Services Impact	Underrepresents microbial contributions to services
Standardized Protocols	Lacks harmonized microbial toxicity assays

CONCLUSIONS

Herbicides, while instrumental in modern agriculture, pose complex ecological challenges that extend far beyond weed control. Their influence on soil microbial consortia—especially in the rhizosphere—triggers cascading effects that alter nutrient cycles, suppress beneficial taxa, and potentially promote antibiotic resistance. These microbial disruptions reshape plant–soil interactions, reduce ecosystem resilience, and compromise vital services such as pollination, pest regulation, and carbon sequestration.

Conventional herbicide risk assessments often overlook these microbiome-mediated effects, focusing narrowly on chemical residues and plant toxicity endpoints. Integrating microbiome-centric metrics into regulatory frameworks—such as microbial diversity indices, functional group profiling, and gene transfer monitoring—offers a path toward more holistic ecological stewardship.

A microbiologically informed approach to weed management can help sustain soil health, foster agroecosystem stability, and safeguard public and environmental well-being. The microbial voice, long silent in regulatory discourse, must now become a guiding force in rethinking agricultural sustainability.

ABSTRACT

Plant breeding is a scientific process based on genetic principles that aims to import desired traits to plants. The development of molecular marker technologies and the application of Marker Assisted Selection (MAS) have accelerated and improved the reliability of breeding efforts compared to traditional methods. The ability to select fruit species based on genetic information, especially in the early stages, offers substantial time and cost savings in the breeding processes. Although genetic maps using molecular markers have been created for many important agricultural species, this data is rarely integrated into commercial breeding programs. The blackberry (*Rubus* sp.) is an example of this due to its high ploidy level and complex genetic structure. In this species, which is difficult to breed conventionally, genetic mapping and genome analysis must first be developed in order to effectively utilize MAS. Widespread wild blackberry populations in Turkey are an important source of genetic diversity and offer the potential to develop local varieties by integrating them into breeding efforts. To benefit from this potential, it is crucial to develop genomic and mapping studies, increase research on MAS, and effectively evaluate genetic resources. In this review, the importance of MAS studies in blackberry breeding and molecular studies on this subject are included.

Anahtar Kelimeler: Blackberry, Marker-assisted selection, Molecular markers

INTRODUCTION

Plant breeding is the development of new plants that possess desirable heritable traits by utilizing differences in genetic structure and natural distribution (Kanlítepe and Duman, 2010). Although advances in agricultural technologies have contributed to yield improvement for many years, changing farming practices, environmental conditions, the evolution of pests, and consumer demands continuously compel breeders to develop new and adaptable cultivars. Traits such as fruit color or disease resistance can be targeted in newly developed varieties. These traits can be transferred to desired cultivars through hybridization from individuals within the gene pool. The acquisition of target traits through hybridization often relies on the broad allelic diversity found in genetic resources such as wild relatives and local varieties; therefore, the conservation and availability of these resources are of great importance for the sustainability of breeding programs. While traditional breeding continues to contribute to yield enhancement, new approaches such as biotechnology are needed to improve its success. In this context, DNA marker technology, based on molecular genetics and genomic studies, holds the potential to increase the accuracy and efficiency of breeding. Molecular markers enable the identification and conservation of individuals with distinct genetic characteristics. The use of this technology

is referred to as marker-assisted selection (MAS), which constitutes one of the fundamental elements of molecular breeding (Tanksley and McCouch, 1997; Gülşen and Mutlu, 2005; Collard and Mackill, 2008).

Molecular markers enable the identification of genes associated with important traits in horticultural crops, and the utilization of this information in breeding programs is achieved through marker-assisted selection (MAS). For a successful breeding program, a large number of progenies must be produced and evaluated; the appropriate number of hybrids depends on the program's objectives, parental quality, and screening methods such as pre-field MAS or greenhouse phenotyping. In many cases, thousands or even tens of thousands of individuals need to be screened, although successful cultivars have also been selected from smaller populations (Caruso et al., 2020; Rojas, 2015). While conventional breeding programs are capable of generating large seedling populations, they often lead to high costs and low efficiency. In contrast, MAS enhances breeding effectiveness by facilitating selection for traits that are otherwise difficult to identify at early stages or those that are recessive (Rojas, 2015). Although MAS provides the opportunity to combine desirable traits more rapidly and with fewer losses, its application in the improvement of complex traits remains limited due to low heritability and environmental effects. Therefore, the integration of large-scale genotyping into breeding systems is critical for the transfer of multiple genes (Xu and Crouch, 2008).

In *Rubus* species, studies aimed at identifying commercially important traits such as resistance to diseases and pests, as well as postharvest durability and processing quality, have facilitated the development of molecular markers that can be employed in marker-assisted selection. However, the limited morphological variation in these species complicates the identification of germplasm and cultivars; therefore, DNA markers serve as an essential tool both for cultivar identification and for the assessment of genetic diversity (Antonius-Klemola, 1999; Ryu et al., 2017). The use of molecular tools in blackberry breeding is of great significance for shortening the breeding process and enhancing production. Nevertheless, the autotetraploid structure of erect and semi-erect blackberry cultivars intended for fresh consumption poses challenges to genetic studies (Foster et al., 2019). In molecular breeding studies of autopolyploids, the high heterozygosity, multivalent inheritance, and difficulties in determining allele dosage in autotetraploid cultivars complicate genetic analyses. In recent years, however, software tools have been developed to overcome these challenges, and a reference genome for diploid *Rubus argutus* as well as high-throughput genotyping platforms have been established. Collectively, these advancements have rendered molecular breeding more feasible in tetraploid blackberries (Johns et al., 2025).

Among berry crops, blackberry is a species in which phenotypic selection can be slow and costly due to polyploidy and its complex hybrid pedigree. However, with the rapid expansion of genetic and genomic resources in recent years, it has become an increasingly strong candidate for marker-assisted selection (MAS) (Foster et al., 2019; Bruna et al., 2023; Paudel et al., 2025). Furthermore, studies in berries have demonstrated that wild relatives and local cultivars provide valuable allelic sources for traits such as resistance and quality, which further reinforces the strategic importance of MAS in blackberry breeding (Migicovsky et al., 2022).

Blackberry (*Rubus fruticosus* L.)

Blackberry, belonging to the genus *Rubus*, is classified within the order Rosales, and the family Rosaceae in general identification the name *Rubus fruticosus* is used (Yıldız, 2017). *Rubus* is well known for its taxonomic complexity (Sochor et al., 2022). The basic chromosome number in *Rubus* species is seven, with ploidy levels ranging from 2x to 14x. Diploids are predominantly sexual, while polyploids may exhibit apomictic reproduction. Moreover, factors such as incompatibility genes and vegetative propagation further complicate research on this

group (Thompson, 1997). Since limited morphological variation makes the reliable identification of germplasm and cultivars difficult, studies focusing on commercially important traits such as disease and pest resistance, as well as postharvest durability and processing quality, have encouraged the development of molecular markers for use in MAS. Consequently, DNA markers have become an essential tool for both cultivar identification and the assessment of genetic diversity (Antonius-Klemola, 1999).

The relatively limited genetic variation in *Rubus* has led to slow progress in breeding, thereby increasing the importance of interspecific hybridization and mutation breeding (Ryu et al., 2017). While genetic diversity studies have been more concentrated in raspberry, where interspecific relationships have been elucidated through molecular markers, the use of DNA-based methods in blackberry has also become widespread. While genetic diversity studies have focused mostly on raspberry and interspecies relationships have been revealed with molecular markers, the use of DNA-based methods in blackberry has become widespread, but difficulties such as limited genetic structure information, genotype discrimination, and the inability to determine heterotic groups persist; moreover, the cost and labor requirements of traditional breeding have made DNA-based analyses a more suitable option (Ochieng et al., 2018). Blackberry is widely cultivated among berry crops in temperate and subtropical regions (Umarusman et al., 2020). Most cultivars, largely originating from North America, are tetraploid ($2n = 4x = 28$) and are extensively grown in the United States (Clark et al., 2007). Nevertheless, the native range of blackberry is considered to be Southern, Western, and Central Europe. Commercial cultivars have been developed in erect, semi-erect, thorny, thornless and, trailing forms, with widely cultivated varieties in both the world and Turkey, including Arapaho, Bursa-I, Bursa-II, Bursa-III, Boysenberry, Black Satin, Cherokee, Chester, Nessy, Dirkson, Darrow, Lawton, Navaho, and Thornless (Zenginbal and Gündoğdu, 2020; Kırıt et al., 2023). Blackberry, a significant crop in Mexico and the United States, is notable for its early fruiting and high economic returns. Its richness in phenolic compounds enhances its nutritional value (Milosevic et al., 2012; Balcı and Keleş, 2019), yet postharvest issues such as softening and leakage complicate transport and storage, thereby limiting its commercial value (Godwin, 2021). The development of large-fruited and high-yielding cultivars through breeding has attracted the interest of small producers, while the expansion of production into different regions has enabled year-round supply. Moreover, the transition from red raspberry to blackberry cultivation has provided advantages for growers due to its lower input requirements (Altunbaş and Pırlak, 2019; Godwin, 2021).

Molecular Markers

Advances in genetics and genomics, particularly through the use of molecular markers, have facilitated the development of genetic mapping studies in crop plants. As a result, more comprehensive linkage maps have been established, extending beyond those based solely on morphological traits. Molecular markers have been successfully applied in various areas, including the assessment of genetic diversity, phylogenetic analyses, gene identification, genome mapping, and marker-assisted selection (Güleç et al., 2010; Iordăchescu et al., 2021). SSR markers are particularly preferred in commercial species due to their high levels of polymorphism and reproducibility, whereas SNPs are notable for their low mutation rates and evolutionary stability (Iordăchescu et al., 2021). However, in blackberry and other *Rubus* species, such studies have progressed more slowly compared to red raspberry, owing to their complex genetic structure and lower economic priority (McCallum et al., 2018).

In linkage mapping studies, various molecular markers such as AFLP, RAPD, SSR, and SNP have been employed to construct genetic maps, thereby enabling the identification of genes or QTLs associated with target traits (McCallum et al., 2018). These developments have contributed to the advancement of genetic research by facilitating the association of traits with

specific chromosomal regions. Since the identification of genes or genomic regions affecting agriculturally important traits relies on examining the relationship between DNA markers and phenotypic traits, this forms the foundation of marker-assisted selection applications. Today, in line with environmental changes and regulatory frameworks, the need for developing traits aimed not only at quality but also at sustainability and environmental resilience has increased (Adhikari et al., 2017; McCallum et al., 2018).

Marker-Assisted Selection (MAS)

In fruit breeding, the improvement process generally takes 20-25 years, which delays the development of new cultivars (Aksu and Çevik, 2015). With the development of molecular markers and genetic maps targeting QTLs in plants, marker-assisted selection (MAS) enables the identification of individuals carrying genomic regions associated with desirable traits, thereby facilitating the transfer of target genes or QTLs into elite germplasm and allowing the process to be completed more efficiently and in a shorter time (Aksu and Çevik, 2015; Karakaş and Bayrıl, 2024).

In MAS applications, marker selection is made by considering factors such as reliability, DNA quality and quantity, technical complexity, level of polymorphism, and cost. The use of markers closely linked to the target gene region increases analytical accuracy. In practice, SSRs are widely used, reliable and polymorphic tools, although they present certain technical and economic limitations, while alternative markers such as STS, SCAR, and SNPs can also be effectively utilized (Collard and Mackill, 2008).

The success of MAS depends on the strength of the marker-QTL/major gene association, the level of recombination, and the capacity to screen large numbers of individuals. However, limitations related to technical infrastructure, cost and labor requirements, and the lack of knowledge on appropriate and cost-effective strategies restrict its application (Güleç et al., 2010; Wannemuehler, 2018). For the effective implementation of this method, genetic maps in which marker sequences are associated with phenotypic or biochemical traits are required and such maps also allow the identification of quantitative traits such as QTLs (Kanlitepe et al., 2010; Vidyagina et al., 2021). Compared to phenotypic screening, MAS is more practical and reliable, as it enables studies independent of environmental influences, saves time and resources for traits that are difficult to identify and allows for early selection by distinguishing between homozygous and heterozygous individuals. Additionally, it is effective in the identification of genetic resources, prevention of varietal confusion, and protection of commercial rights (Yorgancılar et al., 2016).

In marker-assisted selection, the process generally begins with the selection of appropriate parents, at least one of which carries the marker alleles for the target trait. Subsequently, the F1 population is generated, and false hybrids are eliminated through marker screening. In the F2 population, individuals are analyzed with markers, and those carrying the desired alleles are selected. In the subsequent F2:3 and later generations (F3, F4, F5), marker screenings continue, with a particular focus on identifying homozygous individuals and superior lines. In advanced generations (e.g., F5:6), phenotypic evaluations are also considered alongside marker data. In the final stage, selected lines are subjected to comprehensive trials for traits such as yield, quality, and disease resistance. This approach accelerates the breeding process by enabling the early identification of desirable genotypes (Jiang, 2013).

Today, MAS is widely applied, particularly in backcross breeding, where markers facilitate the selection of traits that are difficult to identify phenotypically, enable the early detection of rare individuals linked to the target gene and eliminate the need for an additional selfing step in the transfer of recessive genes. This approach ensures the effective selection of the target region, reduces linkage drag, and simplifies the identification of recurrent parents (Güleç et al., 2010; Xu and Crouch, 2008; Yorgancılar et al., 2016).

Marker-Assisted Selection (MAS) Studies in Blackberry

The initial steps toward marker-assisted selection (MAS) applications in blackberry began with the establishment of marker infrastructure. Lewers et al. (2008) developed hundreds of SSR markers from an EST library of 18,432 clones prepared from “Merton Thornless” tissue, reporting that approximately 30% of these markers were polymorphic. This study laid the foundation for subsequent genetic mapping and MAS applications in the following years.

Subsequently, one of the most important structural traits in blackberry breeding, thornlessness, was introduced into cultivation through the “Merton Thornless” cultivar developed in the United Kingdom and became the primary source transferred into modern cultivars (Clark and Finn, 2011). The genetic basis of this trait was later examined in greater detail through a linkage mapping study conducted in a tetraploid population, in which the thornlessness locus was mapped to LG4 and the primocane-fruiting locus to LG7 (Castro et al., 2013). Thus, the foundation of MAS for these two traits was established. More recently, thornlessness has been further refined by Johns et al. (2025) using a genome-wide association analysis, narrowing its position to the 30.48-36.04 Mb interval on chromosome Ra04, where five candidate genes, including *HOX3* were identified. Moreover, two KASP markers developed in this study predicted the phenotype with 96-97% accuracy across 626 genotypes. This advancement has enabled the rapid and reliable selection of thornless individuals at the seedling stage.

Studies on quality traits also highlight the importance of MAS. In an analysis conducted across the Rosaceae family, 173 alleles associated with sweetness (soluble solids content, SSC) were identified in blackberry, of which 92 were tested using KASP and 48 were validated. Furthermore, a QTL designated *qSSC-Ruh-ch1.1* was reported to increase SSC by +1.5 °Brix (Zurn et al., 2020). Subsequently, in a GWAS performed by Godwin et al. (2025) on 301 genotypes, the heritability values for SSC, pH, and titratable acidity (TA) were found to be 61%, 67% and 70%, respectively; significant regions were identified on Ra02 for SSC and on Ra05 for pH and TA. Candidate genes reported in these regions included *MYB1*, *PEPC*, malate synthase, and *ALMT9*. Similarly, in Godwin’s master’s thesis (2021), six QTLs and 16 candidate genes were identified across four chromosomes in 307 genotypes. These findings demonstrate that sweetness and acidity traits can be effectively supported through MAS.

In terms of postharvest quality, fruit firmness and red drupelet reversion (RDR) represent major challenges. In a GWAS conducted on 300 tetraploid genotypes, Chizk et al. (2023) reported heritability estimates of 68% for firmness and 34% for RDR and identified a negative correlation between these two traits. Among the SNPs associated with firmness, markers were located near genes encoding polygalacturonase and pectin methylesterase. These findings suggest that MAS can serve as a valuable tool in the development of cultivars with firm texture and improved durability.

In addition, diversity and parental selection also contribute indirectly to MAS. AFLP analyses conducted on 81 *Rubus* genotypes collected from Japan distinguished between cultivated and wild materials and demonstrated that hybrid individuals diverged from their parents (Miyashita et al., 2015). Furthermore, RNA-Seq-based SSR and SNP studies performed on *Rubus glaucus* cultivated in the Andes have enabled the evaluation of traits such as thorn presence and anthracnose tolerance in relation to parental selection, thereby demonstrating that MAS can also be integrated into different *Rubus* species (López et al., 2019).

CONCLUSION

Blackberry is a significant species among berry crops, distinguished by both its nutritional content and economic value. Owing to its significance in fresh consumption and its processability in industry, its global production has been steadily increasing each year. However, blackberry breeding is more challenging compared to other berry species. The primary reasons for this include variable ploidy levels, a complex hybrid pedigree, and long generation times. These factors render breeding through conventional methods both time-consuming and costly.

Marker-assisted selection is regarded as an important tool for overcoming these challenges. However, MAS studies conducted on blackberry to date have remained limited. The reasons for this include the insufficient development of large mapping populations, the scarcity of high-density genetic maps, and the relatively recent adoption of high-throughput genotyping approaches. Nevertheless, in recent years, studies on traits such as thornlessness, primocane fruiting, fruit firmness, red seed return (RDR), sweetness and acidity have provided significant progress in this field. In particular GWAS and QTL mapping studies have enhanced the understanding of the genetic basis of these traits and laid the foundation for marker-assisted breeding.

All these developments indicate that MAS may find much broader applications in blackberry breeding in the future. With the diversification of genetic resources, the establishment of larger populations and the use of advanced molecular techniques, MAS will facilitate early selection in blackberry, reduce time and cost losses, and enhance the efficiency of breeding programs.

ABSTRACT

The objective of this research is to explore the photocatalytic properties of poly (vinyl chloride) (PVC) films, both pure and doped with varying concentrations of nanoscale magnesium oxide (MgO), fabricated by the soft chemistry method and deposited using spin-coating technique. The concentrations of MgO used were 3%, 7%, and 10%. Various analytical methods were employed to characterize the samples. The presence of MgO nanocrystals within the PVC films was confirmed through X-ray diffraction, infrared and UV-visible spectroscopies. X-ray diffraction analysis revealed an average particle size of 22.29, 23.77 and 29.68 nm for the MgO with concentration of 3%, 7%, and 10% respectively. FTIR infrared spectroscopy confirmed the presence of peak corresponding to the Mg–O–Mg bond vibration. Optical analysis revealed distinct differences between the spectra of pure and doped matrices. Increasing in doping led to decreased absorption in visible region. Thus, the transmittance drops from 90% (undoped PVC matrix) to 80% (10% MgO doped PVC matrix). Slight redshifted of absorption edge compared to the bulk semiconductor. The optical band gap of the nanocomposites decreased with increasing MgO concentration, ranging from 3.75 to 3.69 eV. Atomic force microscopy also shows a change in the roughness of the nanocomposites film with increasing MgO nanoparticles percentage. Photocatalytic activity assessments demonstrated that the inclusion of MgO nanoparticles enhanced the efficiency of the nanocomposites under UV light. The (PVC/10% MgO) sample exhibited a 65 % efficiency in removing methyl blue (MB) within 150 min, comparable to other samples with lower efficiency. The photodecomposition reaction of MB followed first-order kinetics, characterized by a rate constant (k) of 0.00526 min^{-1} .

Keywords: MgO; PVC films; Xray; FTIR; Doped; Semiconductor; Gap.

INTRODUCTION

Nanocomposites embedded in polymer matrix have gained a lot of interest and thus a numerous research work has been devoted to it. Single polymer matrix is one of the most attractive classes of materials in the world, due to their interested properties and applications. Polymer nanocomposites offer advanced in new technology in various uses and has no environmental benign effects. Moreover, the effective properties of polymer nanocomposites rely on the nature of the components, the shape of the particles, the size and arrangement of the inclusions, the concentration, the volume fraction of the components, extent of dispersion of nanoparticles and interfacial bonding in the polymer matrix. Generally, Inorganic particles in polymer matrix improve density, mechanical, thermal, electronic, magnetic, and redox properties of nanocomposites [1-4]. Among oxides, MgO nanoparticles is a well-known refractory oxide, which has potential advantages with wide bandgap around 7.8 eV. MgO is interesting inorganic substance which has FCC type crystal packing, abundantly used raw material because of its high thermal stability, biodegradability and low toxicity. MgO is a chosen material due it's potential application in chemical industry as it is used as air pollutant scrubber for gases, catalysis, optoelectronics, insulating material filler, refractory materials, and as a catalyst support.[5,6] In photocatalytic application MgO is seen one of the promising photocatalyst and have been successfully applied for methylene blue dye degradation. Doping of MgO is an effective method to increase photocatalytic activity of MgO catalyst. Reports have revealed insertion of silver nanoparticles in the crystal lattice of MgO enhance the photocatalytic activity for dye degradation. [7] The doping of Ag results in lower energy region absorption of light and thus makes possible to extend the photocatalysis in the visible part of electro-magnetic spectrum. Polymers are the dominant materials widely used, owing to their low cost and ease of processing, so they are considered to be versatile, beneficial and economical for their wide spread applications. [8] Polymers like PVC has attained tremendous interest in various life aspects. The interest in PVC have arisen because of its good properties like excellent mechanical properties, highly rigidity than other general thermoplastics materials. The advantage of PVC is that it breaks down easily and does not produce dioxins under natural conditions. PVC also has found good applications in antibacterial and industries. [9, 10]

In this work, an attempt has been made to synthesized MgO nanoparticles and MgO/PVC nanocomposites and investigate their photocatalytic activity. we have also given well full details about the structural, optical, and morphological properties of MgO/PVC nanocomposites film.

MATERIAL METHOD

2.1 Synthesis of Magnesium oxide (MgO) nanoparticles (NPs)

A sol-gel technique was employed to synthesize MgO NPs. Mg (NO₃)₂.6H₂O was taken as a precursor of magnesium and treated with C₂H₅OH. The solution was stirred for 24h until white gel was obtained. After that the mixture was filtered, washed with distilled water and ethanol several times and dried at 100 ° C for 24h. The obtained powder was annealed at 950° C for 36h. Finally the powder was grinded and used for further analysis. The annealing phase results in formation of desired product.

2.2 Photocatalytic procedure

A UV light source (VL -215.LC, 15W), with emission maximum at 365 nm was employed to check the photocatalytic activity of MgO/PVC. 10 ml MB solution with an initial concentration of 10^{-5} mg/ml was taken in a glass beaker. A thin glass strip (5×2.5 cm) containing the films of MgO/PVC nanocomposites was put in the beaker containing MB. The beaker was kept under visible light at a distance 20 cm emitted by a 300 W iodine tungsten lamp (Philips and Co). The whole system was covered by cloth so that natural white light would have no role in catalysis. During irradiation the aliquots of solution was taken out after every 30 min from the reactor and checked by analyzed by a 723 UV–Vis spectrometer (UV-1800 Shimadzu LC 2010-HT).

RESULTS AND DISCUSSION

3.1 Structural study

3.1.1 X-ray diffraction (XRD) analysis

Fig 1 shows the XRD patterns of pure PVC and MgO/PVC nanocomposites films (3, 7 and 10 in wt% n of MgO). From, XRD of pure PVC film, polymer chain have disordered structure indicating amorphous nature [11, 12]. The MgO/PVC nanocomposites film exhibits characteristic peaks of MgO, which appear at 2θ angle 36.23° , 43.04° corresponding to the reflection of (111) and (200) correspond to the cubic phase of MgO (JCPDS card N° 45-0946). The prominent (111) peak of MgO exists but very less intense. From table 1 it can be inferred that intensity and area of MgO/PVC under the peaks at $2\theta = 39.3^\circ$ and 43.04° shifts to right when MgO/PVC loading is increased as compared with that of MgO/PVC, this decrease in lattice parameters reflects formation of mixed phase of MgO/PVC. So it can be inferred that there is change in crystal structure due to varying of MgO/PVC dopant ratio. The interplaner distance d_{hkl} of MgO/PVC were determined using Bragg's law. The change in the interplaner distance d_{hkl} from 2.29 for MgO/PVC (3%) to 2.36 for highest loading of MgO/PVC (10 %) clearly indicates the increase in the lattice size upon doping, which demonstrating a possible extension of MgO lattice. Additionally, to these observations, after increasing doping, the peak of (111) has a high intensity value. Compared to the JCPDS card N° 45-0946, MgO present a texture along the (111) plane.

Fig 1: X-ray diffraction spectra of Pure PVC, MgO/PVC and Ag :MgO/PVC nanocomposites thin films.

3.1.2 The grains size

Debye Scherer's formula was used to calculate size of crystals [18], and the values calculated are recorded in **Table 1**:

$$D = \frac{0.9\lambda}{\beta \cos \theta} \quad (1)$$

Where β = FWHM, θ is the diffraction angle, λ is the X-ray wavelength (1.5405 Å). As the dopant MgO/PVC increases the for MgO/PVC samples the crystallite size (D) also increases.

Table.1. : Structural parameters MgO/PVC nanocomposites thin films

Samples	2 θ (°)	(hkl)	FWMH (rad)	d	D (nm)
3% MgO/PVC	38,03	(111)	0,4	2,35	22.29
7% MgO/PVC	38,16	(111)	0,35	2,35	23.77
10% MgO/PVC	38,3	(111)	0,28	2,36	29.68

3.1.3 FTIR Analysis

In the range of 4000-400 cm^{-1} of the FTIR spectra of pure PVC, PVC/MgO and MgO/PVC/PVC nanocomposites films were recorded as shown in Fig .2. Sharp peak were recorded in the all films at 756 and 904 cm^{-1} . This was attributed to the PVC Bond. With the increase in MgO/PVC loading there is a clear shift towards lower frequencies indicating MgO interactions with C-Cl, C-H bonds of PVC. matrix, due to interaction between MgO and C-Cl, C-H bonds of PVC. [19] The spectrum of MgO/PVC nanocomposites film appears three distinct band is observed in the wave number 615, 1324,1434 cm^{-1} , indicating the bending vibrations of Mg–O–Mg, C-H and C=C, respectively. [20] The spectrum of the MgO / PVC nanocomposite film displayed at 2360 cm^{-1} were assigned to the typical the CH_2 bending vibration mode [21].

Fig 2: FTIR spectrum of PVC and MgO/PVC nanocomposites.

3.2 Optical study

3.2.1 UV–Vis analysis

To determine the optical properties of MgO/PVC nanocomposite thin film UV–Vis Spectroscopy was employed. The UV-VIS absorbance spectra in the region 200–800 nm for doped and undoped films are shown in Figure 3, the pure PVC is completely fully transparent (90%) and has a steep absorption edge at 300 nm. The absorption of the films gets decrease with the increase in MgO amounts concentration as shown in Fig. 3. The absorption region(300-400nm) is probably due to electron transition from valence band to the conduction band. For MgO/PVC composite films this absorption band is quite prominent and wider than PVC pure and MgO/PVC. There is a slight shift in UV absorption intensity in MgO/PVC films. To obtain effective UV absorption the concentration of metal ions needs to be optimized as there is change in absorption with addition of MgO/PVC NPs in PVC matrix [22].

Fig .3: Optical transmission spectra in the UV–Visible region of Pure PVC and MgO/PVC nanocomposites thin films .

3.2.2 Determination of Optical Band

Tauc' plot method was employed to determine the optical band gap of PVC, MgO /PVC and MgO/PVC nanocomposites films. Using the classical Tauc approach, the band gap (E_g) was calculated from the plot of $(\alpha h\nu)^{1/2}$ vs. photon energy ($h\nu$), Figure 4 shows direct optical band gap for neat PVC and MgO/PVC nanocomposites. The optical band gap for PVC was found ~ 4.1 eV. Incorporation of MgO in PVC has great influence on direct transition in nanocomposites as optical band gap gets decreased with increase in concentration of Ag-doped MgO nanoparticles. This is credited to formation of new local levels in the bottom of conduction band which aid in electron transport from valence band through local levels and then to conduction band [23]. These results revealed that the incorporation of PVC served as acceptor for MgO/PVC which reduced the band gap (~ 3.69 eV) for 10% MgO/PVC nanocomposite with red shift confirming p-type conductivity.

Fig .4:The plot $(\alpha h\nu)^2$ versus incident energy $(h\nu)$.

3.3 Morphological study

3.3.1 Atomic Force Microscopy (AFM) analysis

AFM is one of the important analyses for surface characterization. To investigate the topography and roughness of the thin films, AFM 3-D micrographs were recorded. This measurement technique presents digital images allow the quantitative measurements of roughness average, the root mean square and diameter of pores [24] and are estimated and tabulated below.

The change in surface morphology and roughness due to incorporation of Ag doped MgO nanoparticles in PVC membranes is characterized. The mean roughness (R_a) and root mean square roughness (R_q) parameters were measured for these thin films and are displayed in Table 1. Both parameters increased with increase in the Ag :MgO doping weight percentage. It can be seen from Table 1 that mean roughness (R_a) is varied between $1.933 \leq R_a \leq 35.592$ and the root-mean squared roughness (R_q) is varied between $4.117 \leq R_q \leq 644.643$. It is clear that the RMS increased with Ag :MgO content, indicating that PVC/MgO-Ag nanocomposites films have a rougher surface than PVC/MgO nanocomposites. This is an acceptable concurrence with XRD results proposing a debasement of crystallinity and a huge change in MgO/PVC nanocomposites film microstructure. Appropriately, 7% and 10% MgO/PVC/PVC nanocomposites film has the most elevated permeable, which prompts a huge explicit surface region. Thusly, this permeable structure film most promising methods to improve the photocatalyst activity and make the recycling safety.

Samples	Avg. Diameter of pores	Roughness average	Root mean square
Pure PVC	36-360	1.93	4.12
PVC/3%-MgO	25-500	28.49	34.76
PVC/7%-MgO	12.5-375	31.33	37.29
PVC/10%-MgO	31-375	35.59	44.64

Table.2 :Measurements of roughness average, the root mean square and diameter of pores of samples prepared .

Fig.5 shows the two-dimensional and three-dimensional AFM images of the surface topography of PVC pure and MgO/PVC nanocomposites films of different concentrations. It can be seen that the number, diameter of the pores augment with increasing the MgO nanoparticles. may be due to the formation of agglomerates of nanosheets on the membrane surface during the phase inversion process. This is due to increase in the aggregation of tiny particles at some points that contributed in the increase in the roughness parameters [25]. As shown by AFM micrographs and their line profiles, 7%, 10% MgO/PVC nanocomposites films have high porous structure as compared to MgO/PVC. This indicates that Ag doping leads to an increased porosity and as a result lead to a large specific surface area.

Fig .5:AFM for pure PVC and MgO/PVC nanocomposites.

3.5 Photocatalytic tests

The photocatalytic degradation of methylene blue by PVC pure and MgO/PVC nanocomposites are shown in the Figure (6). The methylene blue degradation efficiency increases continuously with increases of time. After two hours of test period, the methylene blue degradation is found to be 17%, 35%, 46% and 52% for PVC and MgO/PVC with concentrations 3%, 7%, 10% respectively. Comparing pure PVC and MgO/PVC the highest activity is observed for the 10% MgO /PVC nanocomposite can be assigned to the most efficient charge separation. The presence of defect content in MgO can reduce electron-hole recombination and increase the photocatalytic activity.

Figure 6. Photocatalytic degradation and (b) the plots $\ln(C_0/C)$ versus time; (c) degradation rate of MB dye under UV light irradiation of PVC and MgO/PVC nanocomposites thin films.

Figure 7 shows the kinetic plot between $\ln(C/C_0)$ and irradiation time " t " for the photodegradation of methylene blue as a function of irradiation time for pure PVC and MgO/PVC nanocomposites at different concentrations and a linear relationship is observed. The rate constant (k) was calculated from the slopes of MgO/PVC (3%, 7%, 10%) nanocomposites and it was found to be $1.64 \times 10^{-3} \text{ min}^{-1}$, $3.50 \times 10^{-3} \text{ min}^{-1}$, $4.24 \times 10^{-3} \text{ min}^{-1}$, $6.25 \times 10^{-3} \text{ min}^{-1}$ respectively. This shows that MgO/PVC has enhanced photocatalytic degradation than pure PVC. In the case of MgO/PVC, the photocatalytic activity increases due to the doping level has

increased. This may be due to the highest porous structure, which provides more active sites for the adsorption of pollutant molecules. The diminution of the band gap (E_g) allow the absorption of more UV light energy and higher generation of electron-hole pairs [26]. This promotes the $\cdot\text{OH}$ and $\text{O}_2^{\cdot-}$ concentrations and thus improves the effectiveness of the photocatalyst. As a result, more electrons and holes can contribute in the photoreaction and so rise the removal of organic molecules [27].

Fig .7: Decomposition of the dyes (MB) under UV light(a) C/C_0 vs time (b) $\ln C/C_0$ vs time (c) % dye degradation vs time.

3.6 Photodegradation Mechanism

Photocatalytic degradation of MgO/PVC/PVC nanocomposites film is initiated by degradation of MgO. Since the degradation of PVC starts indirectly through oxidative radicals generated on doped MgO [28].

In general, when Ag doped MgO is irradiated by UV light, a photoelectron moves from valence band of the semiconductor and iel is the intermediate energy levels generated after doping process .This photon has the energy ($h\nu$) equal to or greater than the band gap. The semiconductor absorbs this radiation and one electron can be excited from the doping donor level to conduction band of the semiconductor and forms cationic radicals (eq ((2)).

The photogenerated holes (h_{vb}^+) react with water molecules to produces the hydroxyl radicals $\cdot\text{OH}$. While the electrons in (CB) conduction band meanwhile reacts with O_2 and generate superoxide radicals anions $\text{O}_2^{\cdot-}$ (eq(3)). the oxygen molecules adsorbed on the semi conductor surface accelerates oxidation process and also prevent any further e^- / holes recombination by trapping electrons.

These reactive species like H_2O_2 , $\text{O}_2^{\cdot-}$ and $\cdot\text{OH}$ radicals produced ,for ultimately help to degrade target pollutants present around it (eq (5,6,7)).

Photocatalytic degradation of PVC is only excited by UV light due to presence of C-C and C-H bonds in polyvinyl chloride. It is proposed that in PVC/MgO nanocomposites, on MgO nanostructures - MB dye generates holes in ground state which takes part in degradation of PVC matrix also with $\cdot\text{OH}$ and $\text{O}_2\cdot\text{H}$. These oxygenated species are initiators of PVC degradation by attacking the polymeric chain.

The oxygen molecules (O_2) have an important central role in the degradation reactions of PVC matrix. Once the carbon-centered radicals included in the PVC polymer chain, their successive reactions lead to the chain cleavage with the O_2 incorporation and CO_2 evolution.

CONCLUSION

A spin-coating approach was used to deposit MgO/PVC/PVC nanocomposites films. A detailed investigation of optical, morphological and structural properties was also carried out. The investigations revealed by FTIR, XRD indicate in MgO NPs. The studies also reveal a clear dispersion of MgO NPs in matrix of PVC. The increase in MgO content also enhanced the crystallinity and grain size. According to AFM we deduce that 7% , 10% MgO/PVC nanocomposites films are porous structure. Films of MgO/PVC nanocomposites are transparent and transmission optical band gap decrease from 4.1 eV to 3.69 eV. The application of MgO/PVC nanocomposites thin films was checked for photocatalysis. The improvement in photocatalytic activity was noticed for the degradation test of organic pollutants under UV light, MgO NPs enhanced photocatalytic efficiency of PVC film.

*** The ZnO is widely used.**

*** It is a very interesting material.**

*** It has various advantages:**

- **Non-toxic,**
- **Abundant on earth**
- **It is a wide gap semi-conductor (3.37eV),**
- **Piezoelectric,**
- **It has a large binding energy of exciton (60meV),**
- Good catalyst and can be used as a gas sensor.**

Corresponding author e-mail: bilgetaskin@karatekin.edu.tr

ABSTRACT

The rising demand for sustainable food systems has led to increased interest in the valorization of agro-industrial waste, especially from cereals and pulses. Despite their abundance of bioactive components, these staple crops produce significant by-products during processing, such as bran, husks, hulls, and seed coats, which are frequently underutilized. The residues comprise valuable constituents, such as dietary fibers, proteins, lipids, vitamins, minerals, and phytochemicals exhibiting antioxidant, antibacterial, and anti-inflammatory effects. Efficient recovery procedures, ranging from traditional techniques such as solvent extraction and alkaline hydrolysis to innovative green technologies including enzyme-assisted extraction, ultrasound, and pulsed electric fields, enable the isolation of functional components. Recent studies highlight their successful applications in food systems, nutraceutical formulations, and biodegradable packaging. For instance, protein hydrolysates from rice husk exhibit anticancer activity, while arabinoxylans from bran display promising prebiotic effects. Furthermore, fermentation and enzymatic processes enhance the bioavailability and functionality of these compounds, while encapsulation technologies safeguard sensitive molecules throughout storage and processing. The processing residues of cereals and pulses have also been investigated for their potential to improve gluten-free product formulations, augment the nutritional and functional properties of baked goods and dairy products, and act as meat and fat replacers in processed foods. However, challenges remain, including the presence of anti-nutritional factors, microbial instability, and undesirable changes in sensory and physicochemical properties. Ultimately, the valorization of cereal and pulse waste offers a promising strategy for resource-efficient, sustainable food production. This review provides an overview of recent developments in recovery technologies, practical applications, and current limitations, while highlighting future directions for incorporating these underutilized materials into high-value food and packaging innovations.

Keywords: Bioactive, By-products, Cereal and pulses, Food waste valorization, Functional food additives, Sustainability.

INTRODUCTION

In recent years, there has been a lot of interest in agro-food waste valorization strategies to establish more sustainable management approaches. Cereals and pulses are grown in great quantities across the globe due to their economic significance as staple foods and dietary sources of energy. The FAO's most current figures show that the global output of cereals and pulses has reached high levels in recent years, and food consumption will continue to rise (OECD-FAO., 2022).

The primary cereals produced are maize, wheat, rice, barley, rye, sorghum, and oat crops (Cardoso et al., 2021), whereas global pulse production is dominated by beans, peas, and chickpeas (Karaca and Nickerson, 2022). However, the food manufacturing industry releases substantial and inevitable waste. Various processing methods (i.e., milling, germination, malting, soaking, peeling, blanching, fermentation, heat processing, drying, canning, freezing, and malting) yield a substantial number of fractions as by-products and wastes, including bran, germ, hull, husk, fiber, seeds, broken grain, leaf, peel, stem, and other elements of the crop. These fractions are underutilized sources of many bioactive components and nutrients. Cereal wastes are abundant in dietary fibers (lignin, β -glucans, hemicellulose), carbohydrates, bioactive peptides, lipids, enzymes, vitamins (mainly vitamin E and vitamin B), minerals, and phytochemicals (phenolic acids, phenols, procyanidins, γ -aminobutyric acid, γ -oryzanol, phytic acid, ferulic acid, etc.) (Skendi et al., 2020). Regarding the pulses, residues provide proteins (mainly from seeds), edible fibers, and bio-functional molecules like minerals (calcium, magnesium, iron, manganese, phosphorus) phenols, carotenoids, and phytosterols to be valorized in different industrial areas (Susmitha et al., 2022; Tassoni et al., 2020). Hence, besides the economic and environmental issues, cereal and pulse processing waste represent a significant loss of biomass with nutritious and functional components. In that respect, the recovery and incorporation of these components as dietary supplements, food additives, coatings, and nutraceuticals gain importance and create new gates for varied technologies. The present section aims to provide an overview of some recent potential applications in the field and the drawbacks associated with the utilization techniques.

RECOVERY AND EXTRACTION OF FUNCTIONAL COMPOUNDS

Bioactive components and fractions can be recovered using conventional and novel techniques consisting of several gradual separation methods. As a common approach, these follow pre-treatment/classification, macro-micro molecule separation, extraction, isolation, and purification pathways which can then be extended by value-added new product development. It is noteworthy to know the structure and physicochemical characteristics of target compounds to determine the appropriate method (Galanakis, 2015; Tassoni et al., 2020). The choice of recovery process primarily depends on the physicochemical properties of the prominent constituents and bioactive components in the waste product.

Many reviews are available with regards to the principle and parameters crucial to the recovery, in particular to yield and composition of the extracts obtained from cereals and pulses, for example, by the applications of supercritical fluid extraction (SFE) (Santana and Meireles, 2023), ultrasound assisted extraction (UAE) (Wang et al., 2021), microwave assisted extraction (MAE) (Duke et al., 2024), and pulsed electrical field (PEF) (Kumari et al., 2018). The detail of recovery, therefore, will not be included in this section. Current status of using these emerging technologies is to determine the most effective/suitable approach, either alone or in combination, for the recovery of different functional ingredients from different matrices.

The milling process separates grain kernels into flour, germ, and bran. By dry fractioning (milling), it is possible to obtain physical-functional bulk fractions that are rich in

proteins, essential amino acids, and minerals (Kamani et al., 2020), but in most cases, further separation stages are needed. Extraction is a particularly important phase of the bioactive recovery process. Conventional methods include alkaline and acid hydrolysis (Buranov and Mazza, 2009), and solvent extraction (Smuda et al., 2018). On the other hand, supercritical carbon dioxide extraction (Benito-Román et al., 2019), enzyme-assisted (Zuorro et al., 2019), ultrasound & microwave-assisted (Ochoa-Rivas et al., 2017), and pressurized aqueous solution extractions (Povilaitis et al., 2015) are some of the innovative, low-cost, green, and sustainable practices being developed.

The utilization of proteins from cereals and pulse wastes is a smart alternative to meet nutritionally well-adjusted consumption demand. Alkaline extraction coupled with isoelectric precipitation stays the most common protein extraction method (Contreras et al., 2019). Besides, enzymatic hydrolysis (Prandi et al., 2021), ultrafiltration (des Marchais et al., 2011), and bioprocessing designs with fermentation (Arte et al., 2019) are some of the other applications well applied for this purpose. In the case of solvent extraction, the type of solvent is critical for efficiency as it yields significantly different antioxidant capacities and bioactive contents (Smuda et al., 2018). In a recent study regarding the hot water extraction of rice husk, peptides in the protein hydrolysate of rice husk have proven an anticancer potential with a cytotoxic effect (Ilhan-Ayisigi et al., 2021). From dietary fibers, arabinoxylans (AXs) which have protective effects against free radicals and exhibit prebiotic potential (Tassoni et al., 2020), were recovered at high yields from rice and wheat brans using water and enzyme extractions (xylanase, cellulase, β -glucanase, α -amylase), one of which was enhanced with extrusion pre-treatment (Fadel et al., 2018; Toft Vangsøe et al., 2019). A significant portion of the dry matter of oats, rye, and barley is composed of β -glucans, which are valuable for metabolic bioactivity (i.e., prebiotic activity, lowering cholesterol). That can be a leading reason for their recovery from the waste of these crops. (Fărcaș et al., 2022). On the other hand, water extraction of xylan from agricultural wastes (brans and seed coats) of different cereals and legumes was achieved. Further enzymatic hydrolysis of xylan (with endoxylanase) produced non-digestible xylooligosaccharides, which are non-cariogenic, low-calorie sugar substitutes with promising applications in the food industry (Palaniappan et al., 2023).

Phytochemicals that exhibit many antioxidative, antimicrobial, antiviral, and anti-inflammatory features (de Villa et al., 2023; Rochfort and Panozzo, 2007; Smuda et al., 2018) are high-value substances abundantly present in the processing residues of cereals and pulses. Recently, it was proven that total phenolics in both wheat and oat brans were shown to increase by +22.5% and +25.8%, respectively, after being subjected to thermal treatment coupled with ultrasound extraction (Călinoiu and Vodnar, 2020). Also, obtaining polyphenols possessing antioxidant activity from industrial cereal solid wastes can be significantly altered by the addition of lactic acid and specific amino acids (glycine or alanine) but also choline chloride (Kottaras et al., 2017). As an emerging technology, pulsed electrical field (PEF)-assisted extraction was effective to exploit these wastes as a source of bioactive molecules. It provides a faster way to recover beneficial compounds while using less energy and solvent (Velusamy et al., 2023). Through fermentation with different cultures, improved structures can be obtained in terms of antioxidants, vitamins, and dissolved or branched protein fractions from by-products and wastes (Ghamry et al., 2023). Then these structures can be used as useful components such as nutraceuticals, coatings, supplements, and packaging materials. Recently, studies on solid-state fermentation, in which microorganisms (*Lactic acid bacteria*, *Aspergillus* spp., *Saccharomyces cerevisiae*, and *Bacillus subtilis*) digest solid substrates in low moisture conditions, took place as an efficient bioprocessing procedure to increase the bioavailability of bound phenolic components and therefore the antioxidant activities of grain-stream wastes. (de Villa et al., 2023). Because research is currently scant, additional investigations i.e., in vitro analysis, on the applicability are required.

Rice bran oil and wheat germ oil may be used to supplement diets due to their immune-boosting qualities some of which come from unsaturated fatty acids, sterols, tocopherols, and carotenoids (Meriles et al., 2022; Saad et al., 2022). Mingyai et al. suggested environment-friendly supercritical CO₂ extraction as a good option for obtaining bran oils (Mingyai et al., 2017). However, during recovery and storage stages precautions should be taken against lipid oxidation due to enzymatic activity.

THE APPLICATIONS IN FOOD INDUSTRY

Developing value-added products from agro-industrial wastes has attracted interest on a global scale. Waste can be used as they are, or it can be valorized to obtain bioactive components for generating novel substances with nutritional and functional advantages. In the course of waste valorization, the functional chemicals in cereals and pulse wastes may become sensitive and unstable when exposed to environmental and process conditions. The encapsulation process is a promising practical option for the stability and protection of bioactive compounds. With this regard, freeze-drying using maltodextrin was found to be the best efficient method to encapsulate the phenolics (protocatechuic acid, *p*-coumaric acid, vanillin, salicylic acid, and catechin) in cornsilk extract (the maize waste) compared to spray-drying and microwave-drying (Pashazadeh et al., 2021). In a recent study examining the effects on health, the rice husk protein hydrolysate was encapsulated with chitosan (Ilhan-Ayisigi et al., 2021). Thermally stable nanoparticles obtained have shown cytotoxic effects promising to produce anticancer peptides and new food supplements that can be derived from them. On the other hand, compounds such as nutraceutical proteins from wastes (pigeon pea milling) can be used as an encapsulation material for water-insoluble bioactive compounds like curcumin (Tapal et al., 2019).

Agricultural waste can be a low-cost alternative to gluten-free food ingredients. Several initiatives have been launched to overcome the nutritional deficiencies of gluten-free products (bread, cake, pasta) and to improve their quality in terms of bioactive compounds and functional properties using rice bran, broken bean flour, chia seed cake, hemp seed cake, okara (soybean process by-product), and chickpea hull (Difonzo et al., 2022). The increased utilization of wastes as replacers and carrier materials can be linked to the development of novel emulsion systems. For example, β -glucan extracted from oat and barley side streams showed great emulsion stability (>80%) and behaved like a viscosifier (Karp et al., 2019). In another study, it was shown that both impure soluble and insoluble oat side streams could be used as innovative bio-based emulsifiers in suspensions, without any further separation or chemical modification (Valoppi et al., 2021). Moreover, as suggested by Tapia et al. 2019 (Tapia-Hernández et al., 2019), prolamin nanoparticles such as zein, gliadin, and kafirin, which are by-products of the cereal starch isolation process, have great potential as pickering emulsion stabilizers once their wettability characteristics are altered. It is possible that oxidative stability, (natural) antioxidant capacity, microbial stability, color, texture, and physicochemical properties of beef, sausage, and mayonnaise-type emulsions can be improved by the incorporation of various extracts from bean hulls and cereal brans or seed coats (Elsebaie et al., 2022; Herrera-Balandrano et al., 2019; Velur Balasubramaniam et al., 2022). In terms of replacement studies, black-gram protein-rich fractions (with germ and aleurone) and soybean oil oleogels structured with rice bran wax worked well as meat and fat substitutes in patty and sausage formulations (Kamani et al., 2021; Wolfer et al., 2018).

The addition of waste products could cause a wide variety of changes in the structural, functional, nutritional, and sensory characteristics of bakery products. Many beneficial effects of fortification or enrichment with waste products from cereals and pulses were observed, such as increased dietary fiber content and technological quality of bread with wheat bran (Chaari et al., 2022), increased nutritional value, phenolics, and antioxidant capacity of crackers with

barley bran (Gangopadhyay et al., 2019), improved syneresis and stability of yogurt with rice bran (Wu et al., 2023), the enhanced profile of flavonoids in rice-based snacks with pea seed coats (Bresciani et al., 2023), and enrichment in a fundamental vitamin, folate, with pulse by-product (Ruggeri et al., 2022). Unutilized, downgraded lentils were found to be a good source of ingredients, contributing positive compositional and functional attributes to the extruded final product (Portman et al., 2020). The ingredients have a strong impact on the structure and quality properties of newly developed products. Color darkening, low specific volume, low hardness in bakery products such as bread (Ni et al., 2020), off-flavor, low digestibility, and presence of antinutrients are some of the negative effects of the grain and pulse waste products that limit their use in the formulations and necessitate alternative solutions (Skendi et al., 2020; Tassoni et al., 2020). Thus, applications like enzymatic treatment, fermentation, and extrusion of underutilized cereal or pulse wastes offer final products with highly soluble materials, micronutrients, and low antinutrients, leading to better digestibility and sensory acceptance (Aktas-Akyildiz et al., 2020; Chakraborty et al., 2022; Kamani et al., 2021). Processing by-products through fermentation enables novel value-added food products. Diverse metabolites can be produced through the fermentation of wastes such as organic acids, natural preservatives (sorbic and benzoic acids), enzymes, alcohols, volatiles, esters, and bioactive peptides (de Villa et al., 2023; Skendi et al., 2020). Also, it was well reviewed that extrusion of some cereals and legumes in the form of a sole or mixture allows producing a wide range of snacks and flours with different structural, nutritional, and functional characteristics, i.e., expansion rate, hardness, crispiness, dietary fiber content, protein content, phenolics, and antioxidant capacities (Grasso, 2020).

Plastics take many years to degrade, threatening the ecology. In this regard, biodegradable polymers and packaging created by the use of grain by-product extracts have become economically important in recent years. Their applications in the field include beneficial structural (pores), mechanical (flexibility), nutritional (fibers, protein), and functional (antioxidants, phenolics) changes, as well as antimicrobial effects (Bilo et al., 2018; Wang et al., 2019; Xu et al., 2022). As a stunning example, the integration of brewers' spent grain extracts into biofilms to generate active packaging enabled antibacterial and antifungal action against *Staphylococcus aureus*, *Escherichia coli*, and *Candida albicans* (Moreirinha et al., 2020).

CHALLENGES AND PROSPECTS FOR THE FUTURE

The use of waste from the cereal and pulse industries presents some challenges. Although these products can be an attractive source for an assorted number of functional compounds or fractions, the process costs and efficiency remain the primary economic and technical obstacles. Now, as well as being economical, sustainable, and environmental-friendly techniques for separation, extraction, and isolation are required to be explored. As new waste sources and purification methods are explored, alternative or combined technologies can be developed for the protection of the sensitive bioactive compounds extracted from these resources. Incorporation attempts for nutritional development can result in alterations in the structural and physiochemical properties of the final product. Aside from the undesired changes in quality, another handicap for the use of cereal and pulse sources is the presence of anti-nutritional factors that cause off-flavors and low bioavailability. Future research on improving sensory features and bioavailability, including the removal or masking of off-flavors, is critical in this context. On the other side, agricultural wastes are biologically unstable considering their microbial load. This can hasten microbial spoilage from the first days of storage and impact product safety. Therefore, the integration of further feasible cleaning and sterilization studies into product development or biosynthesis processes still needs to be addressed to ensure final product safety.

ABSTRACT

The study used a descriptive approach and had 400 participants from Afgoi District Lower-Shebelle, Somalia. A non-simple random selection was used to acquire information from farmers, educators, and workers. To clarify the effect of naturally occurring fertilizer on crop productivity, the data were evaluated using correlation analysis. The majority of responders (56%) indicated significant agreement with the study's findings that green manure improves crop productivity by directly adding nitrogen to the soil, increasing soil fertility. The majority of responders (47.5%), however, were in agreement that plants grown in green manure receive nutrients from deeper levels of soil and release them in the topsoil. On the other hand, the majority of respondents (54%) firmly concur that green manure improves nutrient availability, both macro and micro. The majority of respondents (51%) firmly concur that green manures are environmentally benign under other circumstances. In addition, the majority of responders (57.5%) highly concur that green manure raises the caliber of products and crops. The majority of respondents (51.5%) indicated high agreement with the finding that adding manure to cropland can help keep or raise the level of soil organic matter. However, the majority of respondents (38%) agreed that animal manure includes both macro and micronutrients in both organic and inorganic forms that are essential for crop production. On the other hand, the majority of responders (45.5%) strongly concur that animal dung from a locally accessible source is cheaper than inorganic fertilizer when needed. Similar to this, the majority of respondents (41%) firmly concur that poultry manure is the best animal manure. However, the majority of respondents (51%) strongly concur that adding animal manure to the soil improves its quality. The majority of respondents (55%) said firmly that crop farming is the primary means of subsistence for Afgoi communities. However, the majority of respondents (37.5%) agreed that improvements have been made to the production system over the past two years. On the other hand, the majority of respondents (49.5%) agreed that using organic fertilizer increases crop output per unit of surface area. Similar to this, the majority of respondents (52.5%) strongly concur that fertilizer quality affects crop production.

Keywords: Animal Manure, Crop Production, Green Manure, Organic Fertilizer

INTRODUCTION

Organic fertilizers are crucial for the growth of plants. Organic fertilizers are typically more economical and easily accessible from local sources than chemical fertilizers (Solomon et al. 2012). The foundation of fertile soil is organic matter (Aboudrare 2009). Organic fertilizers are made from biological or living substances. These fertilizers provide nutrients to the soil gradually over time. Whereas artificially created fertilizers, or those obtained via the mining of non-living materials, are known as inorganic fertilizers. Inorganic fertilizers also referred to as chemical fertilizers, are utilized by plants very quickly. There are many different types of organic fertilizers, including Livestock manure from animals, including cows, poultry, goats, and others. Green manure is made from young plants, especially different kinds of legumes. Compost is made from organic agricultural waste like sorghum, maize stalks, or decaying garbage. Organic fertilizers such as sheep manure from farms and chicken manure may aid in crop growth as an alternative to artificial fertilizers (Khan et al. 2005). Organic fertilizer can improve soil fertility and aid in plant growth. Positive actions, including ammonium (NH_4^+), potassium (K^+), and magnesium (Mg^{2+}), are held in biochar, which keeps these nutrients in the soil for an extended period of time and releases them to plants as needed (Lal 1982). The manure from the farm had a long-lasting influence on maize when administered to wheat-based in a wheat-maize crop combination. In soils that had been impaired by erosion, it also performed better at restoring crop yield (Jadoon et al. 2003)). In a field environment, consideration is given to the phosphorus content of maize derived from organic manures, such as crop residue, bio-organic matter, chicken manure, and pressing mud. Researchers discovered that maize includes a significantly high amount of phosphorus (42.68%) compared to other sources, such as poultry manure. When utilized as a source of phosphorus, farmyard manure is substantially more successful than other treatments at boosting the accessibility of phosphorous from soil (Meena et al. 2007). The output of maize grain varies substantially as a result of the addition of organic manures. Although grain production for manure was equal to or, on occasion, greater when phosphorus was obtained from inorganic sources, applying poultry manure produces the highest grain output when compared to another method (Jama et al. 2007).

When applied in place of mineral fertilizers, organic manures increase the grain production of maize (Reddy et al. 2007). Compared to other organic sources, poultry dung offers greater phosphorus that is readily available (Garg et al. 2007). Organic manure sources enhance the accessibility of organic matter, phosphorous, and potassium, as well as plant uptake of these nutrients. Organic amendments also enhance the amount of P and K in the overall plant, as is the height of the plant, LAI, dry matter manufacturing, and LAI. When it comes to plant P and K concentrations, poultry dung offers the best benefits. According to research, increasing the availability of nutrients in the soil from organic manures is what causes improved soil concentrations of nutrients and plant growth (Adnan 2021).

Somalia's agricultural sector faces several challenges, such as low soil fertility, inadequate access to modern farming techniques, and reliance on traditional farming practices. Due to these factors, yields of crops have remained low, and the nutritional security of the population has declined. Organic fertilizers may be used to surmount these obstacles and improve agricultural

output in Somalia. However, more study is needed to determine the effectiveness of organic fertilizers in Somalia and how they affect crop productivity. Little is known and appreciated about organic fertilizers among Somali farmers. The vast majority of farmers in Somalia still use outdated methods and need more access to education and training in contemporary agriculture. Farmers are also not fully informed about the benefits of organic fertilizers and how to use them due to a lack of agricultural extensions and instructional programs. Due to growers' inadequate knowledge and understanding of organic fertilizers, their potential impact on crop output may be restricted, given how seldom they are now employed. The availability of organic fertilizers is a benefit of their use. Organic fertilizers could be hard to come by in Somalia, and farmers might not have the resources or expertise to create them themselves. This might promote the use of costly chemical fertilizers that harm the environment. Due to their limited accessibility and availability, organic fertilizers are challenging to utilize and may not have a significant impact on crop output. The unique climate and soil of Somalia may affect the efficacy of organic fertilizer in addition to challenges with knowledge and accessibility. The effectiveness of organic fertilizers may vary depending on factors such as soil pH, nutrient content, and rainfall patterns.

This research aims to investigate how organic fertilizer affects crop production in Afgoi District-lower Shebelle, Somalia. The general purpose of this study is to identify the role of Organic fertilizer on crop production at Afgoi District-lower Shebelle, Somalia. To Identify the role of green manure on crop production at Afgoi District-lower Shebelle, Somalia. To Determine the role of animal manure on crop production at Afgoi District-lower Shebelle Somalia.

MATERIAL AND METHOD

The research approach of the study was the main focus of this chapter. The chapter includes research design, target population, sample size, sampling procedures, research instruments, and Research quality involves collecting the data, collecting the data, interpreting the data, and finally limiting the study while addressing ethical considerations.

Research Design

The study was conducted using a descriptive design. In order to discuss and examine the impact organic fertilizer has on crop production in Somalia's Afgoi District Lower Shebelle. Utilizing A data obtained from the questionnaire. The target population can be easily reached, the design is efficient, and it is less expensive, all of which make it the best option for this study.

Research Population

The target population of the study was 400 from Afgoi District- lower Shebelle, Somalia.

Sample Size

The researchers used Solvent's formula to calculate the sample size, with a maximum acceptable error of 5%.

$$n = \frac{N}{1 + Ne^2}$$

N: Stands for the population

n. Stands for the sample size

e. Stands for acceptable error

$$n = \frac{400}{1 + 400(0.05)^2} = \text{so the sample was 200}$$

Sampling Procedure

The sampling method was non-random sampling anon-simple random sampling was selected to collect information from the accessible populations of farmers, Agro-students, and workers.

This study's findings about the role of organic fertilizer on crop production have been established in a number of ways. The research's conclusions and findings from a structured questionnaire are discussed in this section. This study's overarching goal is to determine how organic fertilizer affects crop output in Somalia's Afgoi District (lower Shebelle). In contrast, the objective of the study is to identify the role of green manure on crop production at Afgoi District-lower Shabelle, Somalia. to determine the role of animal manure on crop production at Afgoi District-lower Shebelle, Somalia.

RESULTS AND DISCUSSION

The Role of Organic Fertilizers

It is known that soil quality and productivity are increased with organic fertilizer application. For this purpose, many organic fertilization materials are widely used (Figure 1). According to the study's findings, the majority of participants (56%) indicated high agreement that green manure improves crop output by directly aerating soil fertility. In contrast, the majority of respondents (47.5%) thought that plants grown in green manure receive nutrients from deeper soil layers and leave them in the topsoil. The majority of responders (54%) strongly disagree, however, that green manure enhances the availability of both macro and micronutrients. Most poll respondents (51%) completely agree that green manures are environmentally favorable in other contexts. Additionally, the majority of respondents (57.5%) firmly concur that green manure raises the standard of produce and crops.

Figure 1. Organic fertilizers used in improving soil fertility (Singh et al. 2020)

Animal Manure

The majority of respondents (51.5%) answered that they strongly agreed with the claim that spreading manure to croplands can help maintain or raise the level of soil organic matter. On the other hand, a large majority of the participants (38%) said they completely concurred with the assertion that animal dung from locally accessible sources contains both micro and macro nutrients needed for crop productivity in organic as well as inorganic forms.

Crop Production

Organic fertilizers are among the most important inputs in plant production. In fact, it is reported that organic fertilizers can be a good alternative in combating stress factors in plant production (Figure 2).

Figure 2. Effects of organic fertilizer application against stress factors in plant production (Liu et al. 2024)

The majority of respondents (55%) said firmly that crop production is the primary means of subsistence for Afgoi communities, according to the data. Conversely, most respondents (37.5%) believed that the production system had improved during the previous two years. Alternatively, the majority of responses (49.5%) agreed that the application of organic fertilizer increases crop productivity per unit of surface area. In a similar vein, the majority of responders (52.5%) strongly concur that fertilizer quality affects crop productivity.

With regard to the result of this study and based on its objectives, the following could be concluded: The objective of the role of Organic fertilizer on crop production indicates that the use of green manure is widely believed to increase soil fertility through the direct addition of nitrogen, as well as by absorbing nutrients from deeper soil layers and leaving them in the surface soil. Respondents also strongly agree that green manure increases the availability of both macro and micronutrients, is environmentally friendly, and improves the quality of crops and produce.

The objective of the role of animal manure on crop production shows that the use of animal manure can help maintain or improve soil organic matter levels and that it contains both macro- and micronutrients needed for crop production in organic and inorganic forms. Respondents also strongly agree that animal manure from locally available sources is cheaper than inorganic fertilizers and that the best animal manure is from poultry.

Crop productions conclude that crop production is the livelihood strategy for Afgoi communities, with most respondents strongly agreeing with this statement. While a smaller percentage of respondents agreed that the production system has improved in the past two years, the use of organic fertilizers is widely believed to increase crop production per unit of surface area. Respondents also strongly agree that the quality of fertilizers is an important factor in crop production.

CONCLUSIONS

To improve crop production and soil fertility, increase the application of organic fertilizers like green manure and animal faces. To educate farmers about the advantages and appropriate methods for the application of organic fertilizers, services for extension should be made available. Develop and implement operational policies that encourage the creation and application of organic fertilizers. In order to assure the safety and efficacy of organic fertilizers, restrictions and subsidies for their production and distribution may be necessary.

Encourage the use of locally accessible sources of animal dung, particularly poultry manure, as a reasonably priced substitute for inorganic fertilizers. This can entail offering instruction and assistance for small-scale chicken farming. Increase funding for the production of organic fertilizers and the technologies used to apply them. This could result in new, enhanced organic fertilizers that are more successful and efficient at enhancing crop production and soil fertility. Encourage and support farmer cooperatives and associations to promote the use of organic fertilizers and improve crop production. This could include providing access to credit and market information and facilitating collective bargaining for better prices and market opportunities.

INTERVAL VALUED PYTHAGOREAN FUZZY AHP-INTERVAL VALUED PYTHAGOREAN FUZZY TOPSIS METHOD FOR SOLAR POWER PLANT SITE DECISION

Hatice Nida Civan

Istanbul Beykent University, Faculty of Engineering-Architecture, Industrial Engineering Department, Istanbul, Turkey

Corresponding author e-mail: nidacivan@beykent.edu.tr

ABSTRACT

Solar energy systems yield significant results in terms of environmental, economic, and energy security. They are utilized in residential energy production, industrial applications, agriculture, and the transportation sector. As a renewable energy source, solar energy systems contribute to achieving the Sustainable Development Goals. The utilization of solar energy reduces reliance on fossil fuels, thereby enhancing the sustainability of energy systems. This research aims to evaluate Turkey's investment priorities for efficient, reliable, economic, continuous, and environmentally friendly electricity production, leveraging its notable renewable energy resource potential. In this context, existing literature has been utilized, and the Turkish Ministry of Energy and Natural Resources' (ETKB) 2015-2019 Strategic Plan has been taken as a fundamental reference. The proper establishment of solar energy systems is supported by the systematic analysis of the right criteria and alternatives, allowing for the selection of sustainable energy solutions. The decision regarding the suitable site for newly planned renewable energy plants is based on a multidisciplinary approach and complex process management. In modern decision-making processes, various methods have been developed to cope with uncertainty and complexity. IVPF-AHP (Interval Valued Pythagorean Analytic Hierarchy Process) and IVPF-TOPSIS (Interval Valued Pythagorean Technique for Order of Preference by Similarity to Ideal Solution) methods stand out as approaches used together to manage such uncertainties more effectively. This method has been applied to three regions planned for solar energy investment. The application was conducted with five expert decision-makers in the field. IVPF-AHP and IVPF-TOPSIS methods used to improve decision-making processes in solar energy investments guide the successful selection of locations for solar energy projects. A systematic and rational decision-making process has been carried out for the selection of solar power plant sites. The analysis results provided concrete data to decision makers regarding which option represents an efficient investment. The analytical evaluation results are of great importance in terms of both economic and environmental sustainability.

INTRODUCTION

Renewable energy (RE) is characterized by its capacity for continuous replenishment and sustainable utilization. This encompasses a variety of sources, including solar energy, wind energy, hydroelectric power, tidal energy, biomass, and geothermal energy (Liao and Li, 2025).

The advent of competition in the electricity markets necessitates a thorough reevaluation and strategizing of solar energy technologies. Concerns regarding the implementation of solar energy systems within economic frameworks can be articulated in the context of how competition in the electric power sector will empower consumers, leading to enhanced efficiency and reduced electricity costs. This shift toward competitive structures in power markets encourages innovations that may further optimize the utilization of solar energy, thereby facilitating a transition towards more sustainable energy practices (Akhtar et al., 2021). Solar energy, derived from the sun's rays, is one of the most abundant and widely accessible forms of renewable energy. Photovoltaic cells convert sunlight directly into electricity. The inexhaustible nature of solar energy makes it a viable long-term energy option (Sani and Sule, 2020).

The process of generating electricity through photovoltaic (PV) technology produces minimal greenhouse gas (GHG) emissions or other pollutants, resulting in a relatively low environmental impact. This characteristic plays a crucial role in mitigating global climate change and reducing air and water pollution. Consequently, solar energy has emerged as a highly favorable alternative energy source in recent years (Chao and Nguyen, 2024).

INTERVAL VALUED PYTHAGOREAN FUZZY AHP-INTERVAL VALUED PYTHAGOREAN FUZZY TOPSIS (IVPF-AHP)

Kose et al. (2023) delineates the steps of the Interval Valued Pythagorean Fuzzy AHP-TOPSIS as follows:

Definition 1. Let a set X be a universe. A PFS P is an object having the form:

$$P = \{ \langle x, P(\mu_{P(x)}, \nu_{P(x)}) \rangle | x \in X \}, \quad (1)$$

where $\mu_{P(x)}: X \rightarrow [0,1]$ shows the degree of membership and $\nu_{P(x)}: X \rightarrow [0,1]$ shows the degree of non-membership of the element $x \in X$ to P , respectively, and, for every $x \in X$, it holds:

$$0 \leq \mu_{P(x)}^2 + \nu_{P(x)}^2 \leq 1, \quad (2)$$

For any PFS and $x \in X$, $\pi_{P(x)} = \sqrt{1 - \mu_{P(x)}^2 - \nu_{P(x)}^2}$ defines the degree of indeterminacy of x to P .

Definition 2. An IVPFS A can be defined in X as follows:

$$A = \{ \langle x, [\mu_{A_L}(x), \mu_{A_U}(x)], [\nu_{A_L}(x), \nu_{A_U}(x)] \rangle; x \in X \}, \quad (3)$$

where

$$0 \leq \mu_{A_L}(x), \mu_{A_U}(x), \nu_{A_L}(x), \nu_{A_U}(x) \leq 1, \text{ and } \left(\mu_{A_L}(x) \right)^2 + \left(\nu_{A_L}(x) \right)^2 \leq 1 \quad x \in X, \quad (4)$$

Similar to PFSs, the degree of indeterminacy is calculated.

$$\pi_A(x) = [\pi_{A_L}(x), \pi_{A_U}(x)] = \left[\sqrt{1 - (\mu_{A_U}(x))^2 - (v_{A_U}(x))^2}, \sqrt{1 - (\mu_{A_L}(x))^2 - (v_{A_L}(x))^2} \right], \quad (5)$$

Definition 3. The score ($\mathbb{S}^\circ$) and normalized score ($\mathbb{S}^*$) functions for IVPF number $\alpha = ([\mu_{A_L}, \mu_{A_U}], [v_{A_L}, v_{A_U}])$ are given below:

$$\mathbb{S}^\circ(\alpha) = \frac{(\mu_{A_L})^2 + (\mu_{A_U})^2 - (v_{A_L})^2 - (v_{A_U})^2}{2}, \quad (6)$$

$$\mathbb{S}^*(\alpha) = \frac{1}{2}(\mathbb{S}^\circ(\alpha) + 1), \quad (7)$$

Definition 4. The distance measure between two IVPF numbers $\alpha = ([\mu_{A_L}, \mu_{A_U}], [v_{A_L}, v_{A_U}])$ and $b = ([\mu_{B_L}, \mu_{B_U}], [v_{B_L}, v_{B_U}])$ can be defined as follows:

$$d(\alpha, b) = \frac{1}{4} \left(|\mu_{A_L}^2 - \mu_{B_L}^2| + |\mu_{A_U}^2 - \mu_{B_U}^2| + |v_{A_L}^2 - v_{B_L}^2| + |v_{A_U}^2 - v_{B_U}^2| + |\pi_{A_L}^2 - \pi_{B_L}^2| + |\pi_{A_U}^2 - \pi_{B_U}^2| \right), \quad (8)$$

After determining the fuzzy set, AHP determines the weights of criteria by performing pair-wise comparison between criteria. Definition of IVPF is used to present the real case of problems as it involves the uncertainty in linguistic judgments. However, crisp AHP cannot compute this situation. The application steps of IVPF-AHP are given below:

Compromised pairwise comparison matrix $R = (r_{ik})_{m \times m}$ with respect to criteria is constructed using the linguistic terms and their abbreviations given in Table 1.

Table 1. Weighting scale for the IVPF-AHP.

Linguistic Terms	IVPF Numbers			
	μ_L	μ_U	v_L	v_U
Extremely Low Importance—ELI	0.00	0.00	0.90	1.00
Very Low Importance—VLI	0.10	0.20	0.80	0.90
Low Importance—LI	0.20	0.35	0.65	0.80
Below Average Importance—BAI	0.35	0.45	0.55	0.65
Equal Importance—EI	0.45	0.55	0.45	0.55
Above Average Importance—AAI	0.55	0.65	0.35	0.45
High Importance—HI	0.65	0.80	0.20	0.35
Very High Importance—VHI	0.80	0.90	0.10	0.20

Extremely High Importance—EHI 0.90 1.00 0.00 0.00

The differences matrix $D = (d_{ik})_{m \times m}$ is determined between lower and upper values of the membership and non-membership functions based on Equations (9) and (10):

$$d_{ikL} = \mu_{ikL}^2 - \vartheta_{ikU}^2, \quad (9)$$

$$d_{ikU} = \mu_{ikU}^2 - \vartheta_{ikL}^2, \quad (10)$$

where m is the number of criteria.

The interval multiplicative matrix $S = (s_{ik})_{m \times m}$ is determined based on Equations (11) and (12):

$$s_{ikL} = \sqrt{1000^{d_{ikL}}}, \quad (11)$$

$$s_{ikU} = \sqrt{1000^{d_{ikU}}}, \quad (12)$$

The determinacy value $\tau = (\tau_{ik})_{m \times m}$ of the r_{ik} is calculated based on Equation (13):

$$\tau_{ik} = 1 - (\mu_{ikU}^2 - \mu_{ikL}^2) - (v_{ikU}^2 - v_{ikL}^2), \quad (13)$$

The determinacy degrees with $S = (s_{ik})_{m \times m}$ matrix for obtaining the matrix of weights, $T = (t_{ik})_{m \times m}$ is multiplied according to Equation (14):

$$t_{ik} = \left(\frac{s_{ikL} + s_{ikU}}{2} \right) \tau_{ik}, \quad (14)$$

The normalized priority weights w_i is calculated based on Equation (15):

$$w_i = \left(\frac{\sum_{k=1}^m t_{ik}}{\sum_{i=1}^m \sum_{k=1}^m t_{ik}} \right) \tau_{ik}, \quad (15)$$

Each power plant site may have different characteristics and occurrence of one or more risks. Therefore, the evaluation of each defined risk factor for every site is performed by decision-makers. The TOPSIS methodology is applied under IVPFSs to prioritize power plant sites. TOPSIS methodology considers both positive-ideal and negative-ideal solutions in decision-making. TOPSIS outshines with computational simplicity and flexibility to integrate with different areas. The application steps of IVPF-TOPSIS are given in the following steps.

IVPF number-based decision matrix $R = (C_j(x_i))_{m \times n}$ is computed using the linguistic terms given in Table 2, where n is the number of alternatives. $C_j = (j = 1, 2, \dots, m)_{m \times n}$ and $x_i (i = 1, 2, \dots, m)_{m \times n}$ represent values of criteria and alternatives.

Step 2.3.2: The positive ideal points (A^+) and negative ideal points (A^-) are defined based on normalized score function:

$$A^+ = \left(\left[\left(\max_i \mu_{ijL}(\tilde{P}^*), \max_i \mu_{ijU}(\tilde{P}^*) \right) \right], \left[\left(\min_i v_{ijL}(\tilde{P}^*), \min_i v_{ijU}(\tilde{P}^*) \right) \right] \right)_{1 \times n}, \quad (16)$$

$$A^- = \left(\left[\left(\min_i \mu_{ijL}(\tilde{P}^*), \min_i \mu_{ijU}(\tilde{P}^*) \right) \right], \left[\left(\max_i v_{ijL}(\tilde{P}^*), \max_i v_{ijU}(\tilde{P}^*) \right) \right] \right)_{1 \times n}, \quad (17)$$

Step 2.3.3: The weighted distances from A^+ and A^- are computed with respect to criteria weights for alternatives:

$$D(A_i, A^+) = \sum_{j=1}^n w_j [d(A_i, A^+)], \quad (18)$$

$$D(A_i, A^-) = \sum_{j=1}^n w_j [d(A_i, A^-)], \quad (19)$$

Step 2.3.4. The closeness coefficient is calculated for each alternative as follows:

$$F_i = \frac{D(A_i, A^-)}{D(A_i, A^+) + D(A_i, A^-)}, \quad (20)$$

Step 2.3.5. The alternatives are ranked in the descending order. In this study, we determine the riskiest task with the highest F_i value.

Table 2. Linguistic terms to evaluate power plant sites.

Linguistic Terms	IVPF Number			
	μ_L	μ_U	ν_L	ν_U
No relation—NO	0	0	1	1
Extremely Low—EL	0.03	0.16	0.74	0.87
Very Low—VL	0.12	0.25	0.5	0.78
Low—L	0.21	0.34	0.56	0.69
Medium Low—ML	0.3	0.43	0.47	0.6
Middle—M	0.38	0.51	0.38	0.51
Medium High—MH	0.47	0.6	0.3	0.43
High—H	0.56	0.69	0.21	0.34
Very High—VH	0.65	0.78	0.12	0.25
Extremely High—EH	0.74	0.87	0.03	0.16

RESULTS AND DISCUSSION

The average annual sunshine duration of 2,640 hours indicates a consistent and substantial availability of solar energy, suitable for photovoltaic (PV) deployment and solar thermal applications. The average total irradiation intensity, recorded at 1,311 kWh/m²/year, further substantiates Turkey's capabilities in solar energy generation. This intensification enables enhanced energy output from solar installations compared to similar periods and regions.

Figure 1. Solar Power System Diagram

Turkey's southern geographic regions are uniquely positioned in the solar belt, providing vast and unencumbered spaces suitable for deploying solar infrastructure, thereby facilitating large-scale solar projects. The expansive land available for solar energy installations offers Turkey a considerable advantage, particularly in comparison with other countries recognized as sector leaders in solar technology. The pronounced difference in solar irradiance values underscores the untapped potential that Turkey possesses. These factors favor the prospect of enhancing solar energy technology adoption, which can yield significant economic and environmental benefits.

Figure 2. Power plant

Figure 3. Power plant site decision hierarchy

In this context, the insights of five experts are taken into account. These experts possess substantial experience in the field. Their evaluations are gathered through meetings. Based on the study, alternatives have been systematically prioritized by integrating the enhancements of the integrated theory with the combined compromise solution method. This dual approach enables a more nuanced evaluation of options, considering both subjective perceptions of risk and objective trade-offs. Furthermore, to demonstrate the practicality of the proposed model, an illustrative example has been provided, showcasing its effectiveness in real-world applications.

The cost of investment in a power plant emerges as a crucial factor that must be addressed in the process. This expense significantly influences customers' choices regarding the location of their power plants. By offering these costs at a more competitive rate, it becomes feasible to engage a broader customer audience. The findings suggest that by employing this combined methodology, decision-makers can achieve a more balanced consideration of various alternatives, resulting in improved outcomes. Future research may focus on expanding this framework to include additional decision-making contexts. Thereby enhancing its flexibility and robustness across diverse scenarios.

LEGAL ISSUES FACED BY FARMERS AND AWARENESS OF AGRICULTURAL LAW IN THE TRAKYA REGION

Derya İlkay Yılmaz

Tekirdağ Namık Kemal University, Faculty of Agriculture, Department of Agricultural Economics, Tekirdağ, Türkiye

Corresponding author e-mail: deryailkay@nku.edu.tr

ABSTRACT

This study aims to determine farmers' level of legal knowledge, the legal issues they encounter, and their needs for legal support in the provinces of Tekirdağ, Edirne, and Kırklareli. The research was conducted using a face-to-face survey method with 270 farmers. The average age of the farmers was 50.3 years, and their education level was predominantly (44.8%) at the primary school level.

According to the findings, 79.7% of the farmers expressed a desire to gain more knowledge about agricultural law, while 84.4% believed that legal training programs for farmers would be beneficial. Furthermore, 39.4% of farmers stated difficulty in keeping track of legal regulations concerning their agricultural enterprises. Regarding the most significant legal issues encountered, 47.0% of farmers identified problems related to the marketing and trade of agricultural products, 45.9% cited inheritance or transfer procedures, and 38.9% reported legal barriers related to grants, incentives, and subsidies.

The results of the study reveal that awareness of agricultural law in the region is limited, and that farmers require both informational and advisory support in legal processes. It is therefore recommended that educational programs prioritize key topics such as the legal framework of support programs, inheritance law, land ownership, and marketing legislation.

Keywords: Farmer training, rural development, agricultural legislation, legal literacy

INTRODUCTION

The agricultural sector is a strategic area that constitutes the historical foundations of Turkey's social and economic structure. The agricultural revolution, which began with humanity's cultivation of land, gave rise to sedentary life and the concept of private property, thereby creating the need for the protection and management of agricultural lands (Uyumaz & İlhan, 2018). The complex land ownership structure inherited from the Ottoman Empire, coupled with the fact that a large majority of the population was engaged in agriculture in the early years of the Republic, has consistently positioned the policies and legal framework regulating this sector at the forefront of national priorities (Ortak, 2023). Given the profound importance of agriculture for both society and the nation, the establishment of special regulations distinct from general law for matters such as the use, management, and transfer of agricultural lands has become a necessity (Uyumaz & İlhan, 2018).

Agricultural law, which regulates agricultural production, land use, support policies, and the rights and obligations of farmers, is of critical importance for the sustainability of the sector. This field, which diverges from general law with its unique institutions and complex structure, encompasses not only land ownership but also a wide range of topics, including the transfer of agricultural enterprises, inheritance, land consolidation, agricultural lease contracts, the legal

status of animals, and financial collateral mechanisms. For instance, the Soil Protection and Land Use Law No. 5403 seeks to prevent the loss of productivity through the fragmentation of agricultural lands by inheritance (Uyumaz & İlhan, 2018), while the legal right of pre-emption granted to adjacent landowners aims to protect land tenure integrity (Canarşlan, 2020). This legal framework is further detailed with specific regulations such as the pledge of farm animals (Seyhan, 2021) or agricultural lease contracts (Akkışla, 2025), requiring farmers to possess specialized legal knowledge and awareness beyond a general understanding of the law.

A review of the literature reveals that studies on agricultural law are generally conducted from a legislative or policy perspective. While topics such as inheritance (Uyumaz & İlhan, 2018), the right of pre-emption (Canarşlan, 2020), agricultural insurance (Yücer & Altıntaş, 2023), or historical reforms (Ortak, 2023) are addressed, studies examining how these legal regulations are perceived by farmers—the primary stakeholders—along with their levels of legal awareness and the difficulties they face in rights-seeking processes, are limited. However, although agricultural legislation in Turkey covers a broad spectrum, the mere existence of these regulations is insufficient to solve the problems alone. The effectiveness of legislation in practice is directly linked to the level of knowledge and awareness of its target audience, the farmers. The lack of legal knowledge at this juncture prevents farmers from effectively exercising their rights, which leads not only to individual losses of rights but also to the deepening of existing problems and a decline in overall agricultural productivity.

Therefore, studies that reveal farmers' knowledge levels regarding agricultural law, the legal issues they encounter, and their expectations for solutions to these problems are of great importance for policymakers and practitioners. The purpose of this study is to identify the main legal issues faced by farmers in the Trakya Region, the methods they use to cope with these problems, and their levels of consciousness and awareness regarding agricultural law. In this context, the study aims to identify the concrete legal problems experienced by farmers in areas such as ownership, inheritance, marketing, subsidies, and contracts, as well as the obstacles they encounter in following legal regulations, accessing professional legal support mechanisms, and exercising their rights.

MATERIAL AND METHOD

Material

The research data were collected through face-to-face surveys with a total of 270 farmers operating in the provinces of Tekirdağ, Edirne, and Kırklareli. The questionnaire used in the study consisted of both closed-ended and open-ended questions, designed to capture the socio-demographic characteristics of the farmers, their agricultural practices, their level of awareness regarding agricultural law, the legal challenges they encounter, and their needs for training and advisory services.

Method

The target population of the research comprised 68,078 agricultural enterprises registered in the Farmer Registration System (FRS), including 27,637 in Edirne, 16,038 in Kırklareli, and 24,403 in Tekirdağ. Agricultural enterprises with a land size of less than 1.5 hectares or more than 110 hectares were excluded from the study.

The sample size was determined using the finite population formula for proportions (Newbold, 1995; Miran, 2002). In the formula, a 90% confidence level, a 5% margin of error, and $p=q=0.5$ were applied to obtain the maximum possible sample size.

$$n = \frac{N \cdot p \cdot q}{(N - 1) \cdot \sigma_p^2 + p \cdot q} \quad (1)$$

As a result of the sampling, surveys were conducted with 270 farmers. The collected data were analyzed using descriptive statistics (percentages, frequencies, and means). Data processing and tabulation were carried out with the assistance of the SPSS (Statistical Package for the Social Sciences) software.

RESULTS AND DISCUSSION

In this section, the data collected within the scope of the research are analyzed to present the main findings regarding the demographic and enterprise profiles of farmers in the Trakya Region, as well as the legal issues they face and their awareness of agricultural law.

Socio-Demographic and Enterprise Characteristics of Farmers

All 270 farmers participating in the study were male. This finding suggests that the role of agricultural enterprise manager or the individual representing the family in legal processes in the region is predominantly assumed by men. An examination of the age distribution reveals that the sample comprises an experienced and aging population engaged in agricultural production. It is noteworthy that more than half of the farmers (51.85%) are aged 51 and above (Table 1). Consistent with this age profile, a very large majority of the farmers (80.74%) have 16 or more years of agricultural experience, indicating that the sample represents an established group of farmers well-versed in production practices.

A considerable proportion of the farmers (44.81%) are primary school graduates. When combined with middle school graduates, this proportion rises to 61.85%, while the share of those with a high school education or higher remains relatively limited. This distribution suggests that educational attainment may constitute a limiting factor in comprehending complex legal texts and following legal procedures. The majority of households consist of 3–4 members (57.41%), but the number of individuals actively participating in agricultural activities is generally limited to one (42.23%) or two (42.59%).

Table 1. Socio-demographic characteristics of farmers

		Freq.	%			Freq.	%
Age	20-35	41	15,19	Farming Experience (Years)	1-15	52	19,26
	36-50	89	32,96		16-30	82	30,37
	51-70	103	38,15		31-50	114	42,22
	71 and above	37	13,70		51 and above	22	8,15
Education Level	Primary school	121	44,81	Off-Farm Income Source	Retirement pension	103	38,15
	Middle school	46	17,04		No off-farm income	83	30,74
	High school	62	22,96		Self-employed	43	15,93
	Vocational school	18	6,67		Private sector	31	11,48
	Bachelor's	16	5,93		Worker	6	2,22
	No formal education	7	2,59		Public sector	4	1,48
Household size	1-2 members	35	12,96	Family Members in Farming	1	114	42,23
	3-4 members	155	57,41		2	115	42,59
	5-6 members	73	27,04		3	31	11,48
	7 or more members	7	2,59		4	10	3,70

This finding indicates that the regional production model is largely based on small-scale family farming, managed by a limited labor force. With respect to off-farm income, 38.15% of farmers receive a retirement pension, while 30.74% derive their income solely from agriculture. This situation highlights the vulnerability of this group in terms of economic sustainability.

Production Activities and Structural Characteristics of Enterprises

The average landholding size of the enterprises is 25 hectares (approximately 250 decares). When the production pattern is examined (Table 2), it is observed that agricultural activities are predominantly concentrated on field crop farming. A large proportion of farmers cultivate wheat (89.63%) and sunflower (88.52%). These two crops constitute the main production pattern of the region, while other crops such as barley (40.00%) and maize (27.78%) also occupy a significant share. In contrast, the commercial production of vegetables and fruits remains quite limited.

Table 2. Commercially Produced Crops

Field Crops			Vegetables			Fruits		
	Freq.	%*		Freq.	%*		Freq.	%*
Wheat	242	89,63	Tomato	13	4,81	Watermelon	10	3,70
Sunflower	239	88,52	Pepper	8	2,96	Melon	8	2,96
Barley	108	40,00	Cucumber	7	2,59	Almond	3	1,11
Maize	75	27,78	Eggplant	6	2,22	Cherry	3	1,11

Common Vetch	4	1,48						
Alfalfa	3	1,11						
Ryegrass	1	0,37						

*Percentages are based on the total number of respondents (N=270). As multiple responses were allowed, the total may exceed 100%

Additionally, 35.93% of the enterprises are engaged in commercial livestock activities (Table 3). This distribution indicates that livestock farming provides an additional source of income and contributes to activity diversification for producers in the region. Among these enterprises, 32.98% are engaged solely in fattening, 27.84% solely in dairy farming, while 39.18% carry out both activities simultaneously.

Table 3. Distribution of Enterprises by Type of Livestock Activity (n=97)

	Frequency	%
Fattening	32	32,98
Dairy Farming	27	27,84
Both (Fattening and Dairy)	38	39,18
Total	97	100,00

Legal Issues Encountered in Farming Activities

When examining the legal issues encountered by farmers, regulations related to the marketing and trade of agricultural products rank first (47.04%) (Table 4). This finding reveals that beyond production, legal uncertainties in the process of bringing products to market constitute a fundamental challenge for farmers. The second most cited issue is “inheritance or land transfer procedures” (45.93%). This outcome confirms that inheritance law—frequently emphasized in previous studies as a factor leading to the fragmentation of agricultural land—remains a persistent structural problem for farmers in the region. The third issue is legal barriers to accessing grants, incentives, and subsidies (38.89%), indicating that farmers face bureaucratic or legislative obstacles in benefiting from government support programs. Additionally, land consolidation (31.85%) and issues concerning land ownership and use (25.19%) were also identified by farmers as significant problem areas.

Table 4. Legal Issues Encountered in Farming Activities

	Frequency	%*
Legal regulations on marketing and trade of agricultural products	127	47,04
Issues related to inheritance or land transfer procedures	124	45,93
Legal barriers to accessing grants, incentives, and subsidies	105	38,89
Land consolidation	86	31,85
Issues concerning land ownership and use	68	25,19
Difficulties in complying with environmental regulations	55	20,37
Did not experience any problems	7	2,59

*Multiple responses were permitted

Despite the prevalence of these issues, 83.33% of farmers stated that they did not experience any difficulty in dealing with them. This finding can be interpreted in two ways: first, farmers may have become accustomed to legal problems and developed confidence in resolving them through their own traditional methods. Second, and more plausibly, farmers may perceive the concepts of “legal issue” and “experiencing difficulty” differently; that is, while they acknowledge the existence of problems, they may not view recourse to formal legal channels as a viable option for resolution, and therefore do not perceive them as “difficulties.”

For the farmers who did report difficulties in dealing with legal issues, the most common obstacle was inheritance and property processes (40.00%) (Table 5). Within this category, inheritance sharing, transfer procedures, land boundaries, and land consolidation processes were particularly prominent. The second most cited difficulty was systemic barriers (20.00%), with farmers identifying the high costs of litigation and attorney fees, as well as the excessive length of legal proceedings, as fundamental deterrents. This highlights how decisive financial and bureaucratic obstacles are in limiting access to justice. The third-ranking difficulty was lack of knowledge and inability to access support mechanisms (15.56%). Farmers’ statements such as “I don’t know where to apply” or “I can’t find a contact person/expert” reveal a lack of even the most basic knowledge of legal procedures, as well as the inadequacy of institutional support mechanisms. The findings indicate that the difficulties experienced by farmers reflect an intertwined structure, arising from the complexity of the problems themselves, the burdens imposed by the legal system, and deficiencies in the farmers’ informational infrastructure.

Table 5. Difficulties Encountered in Dealing with Legal Issues (n=45)

Category of Difficulty	Freq.	%*
Inheritance and Property Processes (Inheritance sharing, transfer procedures, land boundaries, land consolidation)	18	40,00
Systemic Barriers (High lawyer/litigation fees, lengthy legal processes)	9	20,00
Lack of Knowledge and Access to Support Mechanisms (Not knowing where to apply, unable to find a contact person/expert)	7	15,56
Product marketing, grant procedures	5	11,11
Other (Non-compliance in practice, individual disputes)	6	13,33
Total	45	100,00

*Percentages are based on the 45 farmers who stated they experienced difficulty.

Perception and Awareness of Agricultural Law

To understand farmers' approaches to legal issues and processes, their perceptions of agricultural law and their current levels of knowledge in this field were examined. The findings indicate that farmers largely conceptualize law through the concrete problems they experience and their need for protection, whereas their overall level of awareness remains quite limited. Open-ended responses to the question “What is agricultural law?” reveal that farmers’ perception of law is predominantly practical and experience-oriented (Table 6). The most dominant theme was “Farmer Rights and Protection” (28.16%). This finding suggests that farmers primarily view agricultural law as a protective mechanism that safeguards themselves and their rights. From this perspective, the fundamental function of law for farmers is perceived as “protection.” The second most common theme, “Land, Property, and Inheritance Law” (21.48%), shows that farmers define law mainly through the areas where they encounter the most problems. This indicates that farmers conceptualize law not as an abstract construct, but as the legal counterpart of the concrete problems they face in daily life. The category “Rules and Supports Established by the State” (14.44%) reveals that law is perceived as a framework that not only imposes obligations but also provides advantages, thereby regulating the relationship between farmers and the state.

Notably, 17.78% of farmers stated that they had no direct knowledge or opinion on the subject. The high frequency of responses such as “I don’t know” or “I have no idea” confirms that agricultural law remains a foreign and distant concept for a significant share of farmers. This also reinforces the earlier finding that the perception of “not experiencing difficulty” may, in fact, stem from a lack of knowledge.

Table 6. Distribution of Responses to the Question "What is Agricultural Law?"

	Freq.	%
Farmer Rights and Protection	76	28,16
Land, Property, and Inheritance Law	58	21,48
Rules and Supports Established by the State	39	14,44
Lack of Knowledge / No Opinion	48	17,78
General Regulation of Agricultural Activities	32	11,85
Justice and Equity	10	3,70
Other (Commercial regulations, court, etc.)	7	2,59
Total	270	100,00

The findings regarding farmers' current knowledge levels of agricultural law, their demand for new information and training, and their use of institutional support mechanisms are presented in Table 7. A large majority (79.66%) of farmers expressed a desire to gain more knowledge about agricultural law, while 84.44% believed that legal training would be beneficial. This demonstrates both a high demand for information and a strong openness to education.

However, 48.89% of farmers stated that they do not possess a general level of awareness regarding agricultural law, while only 17.78% reported that they do. Half of the farmers (50.37%) openly declared that they have difficulty understanding basic legal terms. Additionally, 39.44% reported difficulty in keeping track of legal regulations concerning their enterprises. Furthermore, 52.22% of farmers indicated that they do not collaborate with farmer unions or associations—the institutions expected to be the closest and most accessible in resolving legal problems. This suggests that these institutions may either be inadequate in providing legal support, or that farmers are unaware of such support channels or choose not to make use of them.

Table 7. Farmers' Awareness of Agricultural Law and Their Views on Support Mechanisms

	Yes (%)	No (%)	Don't Know / Undecided (%)
Demand for Information and Training			
Would you like to gain more knowledge about agricultural law?	79,66	7,75	12,59
Do you think legal training for farmers would be beneficial?	84,44	7,78	7,78
Current Awareness and Knowledge Level			
Do you have a general level of awareness of agricultural law?	17,78	48,89	33,33
Do you have difficulty understanding basic legal terms related to agricultural law?	50,37	25,19	24,44
Do you have difficulty keeping track of legal regulations concerning your enterprise?	39,44	43,22	17,34
Use of Institutional Support Mechanisms			
Do you collaborate with farmer unions/associations to solve legal problems?	42,59	52,22	5,19

Legal Processes, Barriers to Access to Justice, and Solution Expectations

In this section, farmers' experiences with legal processes, the main barriers they encounter, and their expectations for overcoming these barriers are examined. The findings indicate that farmers face both structural and individual obstacles in accessing the justice system and hold clear expectations regarding both the issues and the actors involved in generating solutions.

A total of 41.85% of farmers stated that they face difficulties in managing the costs of legal processes (Table 8). This relatively balanced distribution suggests a significant differentiation within the farming population in terms of access to legal and financial resources. Despite these challenges, 47.78% of farmers reported being able to resolve their problems effectively, while only 16.30% receive regular professional legal consultancy. This highlights that professional support remains extremely limited in the resolution of legal problems.

Table 8. Farmers' Experiences and Perceptions Regarding Legal Processes

	Yes (%)	No (%)	Don't Know / Undecided (%)
Do you have difficulty getting support for legal issues concerning your enterprise?	40,74	41,85	17,41
Are you able to effectively resolve the legal issues you encounter in your enterprise?	47,78	24,07	28,15
Do you regularly receive legal consultancy for your enterprise?	16,30	81,48	2,22
Do you have difficulty managing the costs of legal processes affecting your enterprise?	41,85	42,59	15,56

When asked about the most significant problems encountered in legal processes, it was observed that the barriers are concentrated on structural deficiencies in the functioning of the system, rather than on individual capacity limitations (Table 9). A majority of farmers (67.04%) identified “the lengthy duration of legal processes” as the most significant problem. This finding indicates that the slow pace of the justice system acts as a major deterrent for farmers. The second most cited problem was “distrust in the system” (35.93%). This perception of distrust, combined with the lengthy duration of proceedings, helps explain the underlying psychological factors driving farmers’ reluctance to engage with the legal system. Barriers such as “not knowing where to apply” (20.37%) and “inability to afford the costs” (16.67%)—which are related to knowledge and financial constraints—rank behind these two fundamental systemic issues.

Table 9. The Most Significant Problems Encountered in Legal Processes

	Freq.	%*
Lengthy duration of the legal process	181	67,04
Distrust in the system	97	35,93
Not knowing where to apply	55	20,37
Inability to afford the costs (Financial barriers)	45	16,67
Inability to find a lawyer	21	7,78
Other (Expert witness issues, lack of attention, etc.)	11	4,07

*Multiple responses were permitted.

The responses to the question, “Which topics should be emphasized more to increase legal awareness?” show that farmers’ training demands closely align with the problems they experience (Table 10). The most frequently requested topic was “Inheritance, Property, and Land Law” (32.22%). This finding confirms that the structural problems identified as the most fundamental legal issues in this study are also perceived by farmers as their most urgent need for information.

The second most cited topic, “General Farmer Rights and Legal Processes” (26.67%), indicates that beyond specific issues, farmers need basic knowledge of the general legal framework that protects them and the mechanisms available for exercising their rights. Following these, “State Supports and Policies” (18.15%) reflects farmers’ desire to understand the legal framework of their financial relations with the state.

These results clearly demonstrate that the content of any legal training program designed for farmers should primarily be structured around these three core areas.

Table 10. Priority Topics for Legal Awareness Training

	Freq.	%
1. Inheritance, Property, and Land Law (Inheritance sharing, inheritance lawsuits, land consolidation, land laws, title deeds, and boundaries, etc.)	87	32,22
2. General Farmer Rights and Legal Processes (Farmer rights, protection of rights, functioning of legal processes, information on legal rights)	72	26,67
3. State Supports and Policies (Subsidies, grant procedures, state policies, updates on new developments)	49	18,15
4. Law Specific to Agricultural Activities (Livestock and agricultural law, product marketing, environmental and water laws, commercial law)	40	14,81
5. Other (Need for more expert witnesses, seminars and meetings, clearer explanations)	22	8,15
Total	270	100,00

Finally, the actors expected to play a role in this information and support process have been clearly identified (Table 11). Farmers' expectations for legal support are concentrated on two main actors: "Legal Professionals" (40.74%) and "Agricultural Institutions and Experts" (34.08%). This indicates that farmers place their trust both in specialized legal knowledge (lawyers) and in institutional structures that are the closest and most accessible to them (such as chambers of agriculture and provincial/district directorates of agriculture). Particularly noteworthy are the responses categorized under "Mixed Support Models" (11.85%), such as "lawyer and agricultural engineer," which emphasize the farmers' demand for an interdisciplinary support mechanism capable of addressing both the legal and technical dimensions of their problems.

Table 11. Expected Actors for Legal Support

	Freq.	%
1. Legal Professionals (Specialized lawyers, law firms)	110	40,74
2. Agricultural Institutions and Experts (Provincial/district directorates of agriculture, chambers of agriculture, agricultural engineers, cooperatives, farmer unions)	92	34,08
3. State and Public Institutions (Ministry of Agriculture and Forestry, municipalities)	36	13,33
4. Mixed Support Models (Lawyers and agricultural engineers, village heads and cooperatives, state and lawyers etc.)	32	11,85
Total	270	100,00

CONCLUSIONS

This study, conducted through surveys with 270 farmers in the provinces of Tekirdağ, Edirne, and Kırklareli, examined farmers' knowledge levels of agricultural law, the legal issues they encounter, and their needs for legal support. The research results reveal that farmers' awareness of agricultural law in the region is limited, and there is an urgent need for information, support, and systemic improvements in legal processes.

The research further demonstrates that a large majority of farmers wish to gain more knowledge about agricultural law and believe that legal training programs would be beneficial. This indicates that policies aimed at enhancing legal literacy are of critical importance, not only for protecting farmers' individual rights but also for ensuring the sustainability of agricultural production. In this context, it is essential to convey priority topics—such as inheritance law, land ownership, land consolidation, marketing legislation, and the legal framework for state supports—to farmers through clear, practice-oriented content. Delivering these trainings on a regular and continuous basis via local agricultural directorates, chambers of agriculture, and farmer unions, and making use of farmers' existing information networks, will significantly contribute to strengthening their legal awareness.

In addition, the establishment of specialized legal consultancy centers in the field of agricultural law, with services provided free of charge or at a low cost, would enable farmers to resolve their legal problems more quickly and effectively. It is also recommended to disseminate practical, step-by-step guidance materials—such as guidebooks, informational brochures, and online platforms prepared in simple and accessible language—on topics including agricultural support procedures, inheritance processes, and marketing regulations.

Efforts to increase legal awareness should not rely solely on lawyers but should also be carried out through institutions that farmers already interact with—such as chambers of agriculture, agricultural directorates, and cooperatives—by integrating technical expertise with legal knowledge. Such an approach would strengthen the effectiveness of awareness-raising efforts. Consequently, by establishing a more reliable, transparent, and accessible legal system, farmers' trust in law will be reinforced, thereby contributing both to the protection of individual rights and to the achievement of regional agricultural development goals.

ABSTRACT

Almond (*Prunus dulcis* Mill.) is one of the most important nut crops cultivated worldwide due to its high nutritional value and economic significance. Across different production regions, almond exhibits broad genetic diversity, the assessment of which is crucial for breeding programs aimed at improving stress tolerance, fruit quality, and yield. This review provides a comprehensive evaluation of recent molecular characterization studies that employed various molecular marker systems to assess the genetic diversity of almond genotypes. Among these, simple sequence repeat (SSR) markers have emerged as the most widely used and reliable tools due to their high polymorphism, codominant inheritance, reproducibility, and strong discriminatory power. Evidences from these studies indicate that genotypes typically cluster according to their geographical origin and genetic background, thereby contributing to the development of targeted breeding strategies. Furthermore, molecular data serve as a valuable resource for the conservation of genetic materials and for the identification of promising genotypes that can be exploited in hybridization programs. This review underscores the significance of integrating molecular approaches into almond breeding programs to facilitate the development of new cultivars and ensure the sustainable management of genetic resources. Ultimately, such integration will enhance the planning and effectiveness of future breeding efforts.

Keywords: Almond, Genetic Diversity, Molecular Characterization, Molecular Markers, SSR Markers

INTRODUCTION

Almond (*Prunus dulcis* (Miller) D.A. Webb) belongs to the genus *Amygdalus* within the subfamily *Prunoideae* of the family *Rosaceae* (Özbek, 1978). It is recognized as a nut crop of high nutritional value (Topçuoğlu & Yılmaz-Ersan, 2021). Native to Central and Western Asia, *P. dulcis* is widely distributed worldwide and constitutes an important hard-shelled fruit species cultivated across many regions of Türkiye (Dokuzoğuz & Gülcan, 1973; Küden & Küden, 2000). Owing to its geographical position, Türkiye is both a center of origin for many fruit species and part of the natural distribution range of almond (Özbek, 1978). In Türkiye, almond occurs naturally in almost all regions except the high plateaus of the Black Sea Region (Küden et al., 2000). According to FAO statistics for 2023, global almond production was 3,513,970.31 tons (Anonymous, 2025a).

Advances in DNA technologies have provided powerful tools for plant breeding, analysis of genetic structures, and elucidation of evolutionary relationships. With the adoption of molecular markers such as isoenzymes, RFLP, RAPD, and SSR, research emphasis has shifted from phenotype- to genotype-based analyses (Aka Kaçar, 2004). Since the 1990s,

molecular markers have become integral to agricultural production, particularly in plant breeding. These tools enable the rapid acquisition of detailed information on the genetic attributes and inheritance patterns of economically important crops. Such information shortens breeding timelines in perennial fruit species and yields substantial savings in land and labor. Moreover, molecular marker-derived data support the development of higher-quality, higher-yielding cultivars by researchers working in fruit production and breeding (Aksu & Şahin Çevik, 2015). Because morphological, physiological, and cytological traits may be insufficient for robust plant systematics, there is growing reliance on molecular approaches to better characterize genetic variation (Yılmaz, 2021). Genotypes produced through breeding are new individuals and therefore constitute valuable plant material (Gök et al., 2025). Consequently, the identification, conservation, and molecular characterization of newly developed almond genotypes—and the incorporation of superior genotypes into subsequent breeding programs—are of paramount importance (Gök et al., 2020).

The objective of this review is to systematically examine molecular characterization studies in almond that employ molecular markers and to provide a comprehensive synthesis of the current state of knowledge. By comparing different marker systems, we aim to identify the most effective approaches for the evaluation of almond genetic resources.

MOLECULAR MARKERS

Molecular markers are essential tools for elucidating the genetic basis of phenotypic diversity and quantifying genotypic polymorphism. Over the past five decades, marker technology has progressed from a handful of isoenzyme markers to an almost limitless array of DNA-based systems (Arús, 2017). Because morphological traits are influenced by the environment, various fruit species are now characterized using molecular markers. A molecular marker is defined as a DNA sequence or protein located on a chromosome or organelle (or encoding such regions) that reveals polymorphism among genetically distinct individuals. A marker may be a protein, a gene, a gene fragment, or a sequence in a non-coding region (Kaçar et al., 2006). DNA-based markers are stable, detectable in all tissues, largely unaffected by environmental conditions, and generally follow simple Mendelian inheritance as codominant or dominant loci (Williams et al., 1990).

APPLICATIONS OF MOLECULAR MARKER TECHNOLOGY

Molecular markers are widely applied in plant genetics for the improvement of qualitative and quantitative traits, selection, genetic and linkage mapping, cultivar identification and protection, and the estimation of genetic distances among genotypes (Bilgin & Korkut, 2005).

ESSENTIAL CHARACTERISTICS OF MOLECULAR MARKERS

Marker systems differ in ease of use, reproducibility, level of polymorphism, and information content. A key distinction is whether markers are dominant (e.g., RAPD, AFLP, ISSR) or codominant (e.g., SSR, SNP, SSCP, CAPs). Codominant markers permit discrimination between homozygous and heterozygous individuals because both parental alleles can be detected; they are therefore considered more informative than dominant markers, which cannot distinguish heterozygous from homozygous dominant genotypes (Kaçar et al., 2006).

MOLECULAR MARKER-BASED STUDIES ON THE GENETIC DIVERSITY OF ALMOND

Molecular markers are highly effective for assessing genetic divergence at species, genus, and family levels (Federici et al., 1998). Numerous studies in Türkiye and worldwide have addressed the identification and characterization of almond genotypes. Since the advent of PCR-based markers, the use of molecular tools in almond has increased steadily. The principal marker systems employed include isoenzymes, RFLP, RAPD, SSR, AFLP, and sequence-based markers.

Isoenzymes were the first molecular markers used in almond studies. Although codominant and reproducible, they are constrained by the limited number of loci detectable with traditional staining methods and by low variation at many loci (Company et al., 2012). RFLPs have been used to construct genetic maps, identify cultivars, and characterize almond germplasm (Viruel et al., 1995; Company et al., 2012). RAPD markers—PCR amplifications using arbitrary primers—have been useful for characterizing genetic resources (Bartolozzi et al., 1998; Martins et al., 2003; Shiran et al., 2007; Company et al., 2012), but their dominant nature and limited reproducibility restrict their utility for cultivar identification and mapping. SSR (microsatellite) markers, developed for almond from *Prunus* genomic sequence resources (Testolin et al., 2004; Company et al., 2012), have proven particularly effective for inferring genetic relationships, cultivar identification, and mapping due to their high polymorphism, codominance, and cross-transferability among related species (Company et al., 2012). Microsatellites consist of tandem repeats of 1–6 bp units along chromosomes. Polymorphism arises from differences in repeat number; each distinct band represents a different allele. Flanking sequences are locus-specific and allow the design of SSR primers to amplify the target locus by PCR. As a codominant system, SSRs enable discrimination between homozygous and heterozygous alleles. PCR amplification followed by electrophoretic separation provides locus-specific insights into genomic variation (Şimşek et al., 2018).

Bartolozzi et al. (1998) analyzed genetic relationships among 17 almond genotypes and one peach genotype using 37 RAPD markers and, despite the obligate outcrossing nature of almond, reported limited genetic diversity; RAPD data grouped accessions into three clusters with similarity indices ≥ 0.75 . Aka Kaçar et al. (2003) assessed genetic diversity in eight cultivars and 21 almond hybrids (crosses between ‘Gülcan 1’ and ‘Ferragnes’) using 12 SSR primers; 10 of the 12 SSRs were polymorphic (3–5 alleles per primer), nine primers conformed to expected Mendelian segregation, and some hybrids were identified as outcrosses. Küden et al. (2004) evaluated 14 local genotypes and ‘Texas’ using 11 RAPD primers; genotypes 47-1, ‘Hacı Alibey’, and ‘Texas’ were most similar, whereas 101-9 was most divergent. Bayazit and Küden (2007; 2011) performed RAPD-based molecular identification of 69 wild almond accessions from various regions of Türkiye together with cultivated almonds (‘Nonpareil’, ‘Cristomorto’) and selected local genotypes [‘Hacı Alibey’ (48-5), ‘Gülcan-1’ (101-23), and 101-13]. Wild almonds from Konya-Ereğli, Nevşehir-Göreme, and Niğde were similar morphologically and molecularly, while those from Gaziantep and Şanlıurfa-Birecik formed two groups. In the resulting dendrogram, cultivated almonds (*P. dulcis* L.) clustered with wild types selected from Central Anatolia. Shiran et al. (2007) examined genetic relationships among Iranian almond cultivars, major foreign cultivars, and three related species using 42 RAPD and 18 SSR markers; eight unidentified ‘Shahrodi’ accessions and wild almonds (*P. communis*, *P. orientalis*, *P. scoparia*) were included. Of 729 RAPD bands, 664 were polymorphic; SSR loci yielded 3–10 alleles per locus (mean 6.64). Both systems effectively discriminated genotypes: cultivated almonds clustered with *P. communis*, while *P. orientalis* and *P. scoparia* were

separated from the remaining *P. dulcis*. Sorkheh et al. (2007) analyzed 45 cultivars from Iran, Europe, and the USA with AFLPs (19 primer combinations), detecting 781 polymorphic bands out of 813 (96.23%). Genetic similarity ranged from 0.50 to 0.96, marker indices from 51.37 to 78.79, and PIC from 0.56 to 0.86; clustering clearly separated genotypes and wild species by origin and lineage, revealing substantial diversity. Martí et al. (2009) investigated 63 local and international cultivars from Spain using 19 SSR markers, obtaining on average 17 alleles per primer (88–260 bp). Observed heterozygosity was 0.72, higher than reported for other *Prunus* datasets. Dendrograms grouped cultivars by geographic origin, indicating distinct evolutionary trajectories of almond ecotypes; SSRs proved effective for cultivar identification, relationship inference, and pedigree analysis. Hamzaoui et al. (2013) evaluated 68 Moroccan local genotypes and 32 foreign cultivars from nine countries using 16 SSRs, detecting 234 alleles (89–252 bp); alleles per locus ranged from 4 to 24 (mean 14.63), with mean $H_o = 0.62$ and $H_e = 0.79$. All SSRs were highly polymorphic and discriminative; UPGMA clustering grouped accessions by geographic origin, with Moroccan materials forming a distinct cluster. To address self-incompatibility and limited market interest in local hard-shelled types, Açar et al. (2013) initiated crosses between self-incompatible local cultivars ('Gülcan 1', 'Gülcan 2', 'Akbadem', 'Nurlu') and self-compatible foreign cultivars ('Lauranne', 'Guara', 'Moncayo') to develop late-flowering, self-compatible almonds. The 2009 crosses yielded 6,116 seeds and 4,082 F1 plants (66.7% germination). S-allele screening by PCR identified 1,743 self-compatible F1s. Regarding 'Guara'—widely cultivated in Spain and suspected to be related to the Italian cultivar 'Tuono'—Dicenta et al. (2015) compared 'Guara', 'Tuono', and presumptive clones 'Supernova' and 'Mazzetto' using 12 SSRs at INRA and 23 additional SSRs from multiple reference collections (CEBAS-CSIC, INRA, IRTA, University of Bari). Across 35 SSRs, 'Guara' and 'Tuono' shared identical DNA fingerprints, demonstrating that they are the same cultivar. Rigoldi et al. (2015) assessed genetic diversity in almond from Sardinia and Apulia using 11 SSRs. Sardinian germplasm exhibited high polymorphism (mean 14.5 alleles per locus; mean heterozygosity 0.71). Model-based clustering resolved two genetic groups; most Sardinian accessions, all commercial cultivars, and most Apulian accessions fell into the first cluster, with Sardinian accessions largely distinct from commercial materials. Yılmaz (2017) selected late-flowering genotypes suited for fresh ("çağla") and nut use from seedling populations in Araban and Yavuzeli (Gaziantep) and characterized them with SSRs, retaining selections for future breeding. Zeinalabedini et al. (2019) analyzed 158 *Prunus scoparia* genotypes—an economically and ecologically valuable wild species with traits such as self-fertility and tolerance to drought and fungal diseases—using 36 SSRs. High genetic diversity was detected, and genotypes clustered by geographic origin, underscoring *P. scoparia* as a valuable gene pool for almond improvement. Dikmetaş (2020) determined sweet/bitter kernel alleles in local cultivars ('Nurlu', 'Hacı Alibey' (48-5), 48-1, 'Akbadem', 17-4, 'Gülcan-2' (101-13), 'Dokuzoğuz-2' (120-1), 'Gülcan-1' (101-23)) using an SNP marker: six cultivars were genotypically homozygous sweet (Sk/Sk) despite sweet phenotypes in all, while two were heterozygous sweet (Sk/sk), suggesting a preference for homozygotes in future breeding to avoid recessive bitter progeny. Serdengeçti (2020) examined genetic relationships among four peach cultivars ('Küden', 'Tanrıver', 'Balcalı', 'İlayda') and various commercially important *Prunus* taxa (cherry, nectarine, plum, almond, apricot, peach) using 24 SSRs. Twenty primers amplified 126 bands, all polymorphic. The highest band numbers (11) were produced by BBCT017, BBCT004, BBCT001; the lowest (2) by MA040 (mean 6.3). PIC values ranged up to 0.95 (BBCT025, BBCT005), with a minimum of 0.49 (BBCT018). Dendrograms grouped 'Küden' with 'Fantasia' nectarine, 'Rio Oso Gem' and 'Üstün' peach; 'Balcalı' clustered with 'Extreme Candy' nectarine, 'Extreme July', and 'Transvalia'. The study emphasized increasing SSR primer numbers to refine relationship inference. Hasanbegović et al. (2021) characterized 60 almond genotypes from Bar (Montenegro) and Šibenik (Croatia) using ten SSRs—nine

derived from *Prunus persica* (UDP and BPPCT loci) and one from *P. armeniaca* (PacA33)—and detected high polymorphism, revealing genetic differentiation between regional populations. Esgandaripirmorad et al. (2022) evaluated 22 cultivars from eight countries with 28 SSRs, detecting 265 alleles (mean 9.46 per locus), an effective allele number of 5.85, $H_o = 0.75$, and $H_e = 0.76$. Locus CPDCT042 showed the highest allele number and heterozygosity; 21 loci produced cultivar-specific alleles in 17 cultivars. UPGMA, PCoA, and STRUCTURE clustered accessions into three groups, with Turkish cultivars forming a distinct cluster; the greatest genetic distance was between ‘Nurlu’ and ‘Cristomorto’, and the closest between ‘Nonpareil’ and ‘Sonora’. Results support fingerprinting and breeding. Mahmood et al. (2023) analyzed 12 Iraqi genotypes using RAPD and ISSR markers. Both systems produced polymorphic bands (means: RAPD 5.8; ISSR 7.6). PIC values ranged 0.64–0.84 (RAPD) and 0.52–0.91 (ISSR). Jaccard similarities spanned 0.34–0.77 (RAPD) and 0.35–0.79 (ISSR), with four clusters recovered in each analysis, indicating substantial within- and among-group diversity—valuable for breeding and conservation. Uzun et al. (2024) examined natural Turkish genotypes, foreign commercial cultivars, and intra-specific hybrids using ten ISSR primers, yielding 99 bands, 84 polymorphic. UPGMA separated genotypes into two main groups (similarity 0.67–0.97); 98 of 141 hybrids clustered in the first group. Five primers exhibited 100% polymorphism, and seven exhibited $\geq 80\%$ polymorphism, providing actionable information for breeding. Gök (2024) investigated genetic relationships among selected genotypes from Nevşehir, Niğde, and Mersin-Mut and several *Prunus* species, rootstocks, and cultivars using 18 SSRs. The highest band number per primer was 11 (MA014), with some primers producing one band (mean 3.38); mean polymorphic bands per primer were 2.5. In total, 61 bands (45 polymorphic) were obtained, with mean polymorphism of 33.33%; several primers (1, 2, 4, 14, 16, 18) showed 100% polymorphism. Dendrograms revealed two major clusters: ‘Rootpac-R’ separated on the first main branch; all others formed the second branch, which split into two sub-branches—one including ‘Pabuç’ and ‘Gülcan-2’, and the other comprising the remaining genotypes. Results provide genetic insights to better plan almond breeding. Yangöz & Güney (2025) assessed nine genotypes from Yozgat together with seven local/foreign cultivars using 18 SSRs, detecting 132 alleles (mean effective alleles 4.90), $H_o = 0.73$, $H_e = 0.78$, and a maximum PIC of 0.83, indicating high discriminative power. UPGMA and PCoA resolved two main groups and four subgroups, consistent with STRUCTURE, highlighting the richness and breeding value of regional germplasm. Kırca (2025) analyzed pomological, colorimetric, and genetic traits of 38 naturally occurring genotypes from Tavas (Denizli). Cluster analysis grouped genotypes into two main clusters; genetic distances ranged from 1.21 to 10.05. PCA showed that the first five components explained 68.84% of total variation; the largest contributors to PC1 were b^* (0.433), fruit length (0.389), and kernel length (0.375), whereas chroma (0.429) and kernel width (0.200) contributed most to PC2. The population exhibited substantial genetic diversity; genotypes 1, 5, 9, and 17 were identified as valuable breeding resources. Studies employing diverse molecular marker systems to assess almond genetic diversity provide valuable data for the management of genetic resources. A review of the literature indicates that, among the molecular markers applied in almond genetic diversity studies, SSRs are the most widely used, followed by RAPD and ISSR markers. The predominance of SSR markers can be attributed to their superior features, including high levels of polymorphism, codominant inheritance, and reproducibility. Owing to these advantages, SSRs stand out as the most reliable and widely adopted system. Although dominant markers such as RAPD and ISSR are relatively simple and rapid to apply, they are limited in terms of reproducibility and discriminatory power. By contrast, AFLP and SNP markers provide more detailed information and have proven particularly effective in discriminating among genotypes. Overall, molecular analyses have consistently demonstrated that almond genotypes cluster according to their geographical origin.

CONCLUSIONS

This review examined studies conducted in Türkiye and worldwide that utilized molecular markers to identify almond genotypes, assess their genetic diversity, and elucidate relationships among them. Various molecular marker systems, including SSR, RAPD, AFLP, ISSR, and SNPs, have been employed. Among these, SSR markers have proven to be particularly powerful for genotype identification, pedigree analysis, and the determination of genetic relationships with other *Prunus* species and cultivars. Due to their high polymorphism, codominant inheritance, and reliability, SSRs have become the most widely preferred markers in almond breeding studies.

The results consistently demonstrate that both Türkiye and other regions of the world harbor a rich genetic diversity of local almond genotypes. These valuable genetic resources represent an important gene pool for almond breeding programs. Dendrograms derived from molecular analyses classify almond genotypes according to their geographical origin, clearly revealing similarities and differences among populations from different regions. Such analyses provide detailed and reliable insights into almond germplasm, thereby offering critical information to support the design and implementation of more targeted and effective breeding strategies in the future.

ABSTRACT

Global warming has emerged as a critical driver of change in freshwater ecosystems, exerting multifaceted influences on the physical, chemical, and biological characteristics of freshwater systems. Rising air temperatures cause to increase in surface water temperatures, which reduces the solubility of dissolved oxygen and intensifies thermal stratification, promoting hypoxic or anoxic conditions in deeper layers.. Enhanced evaporation rates and altered precipitation patterns exacerbate seasonal and annual fluctuations in water levels, concentrating contaminants and reducing the self-purification capacity of lotic systems. Concurrently, elevated runoff during extreme rainfall events transports greater loads of nutrients and associated agrochemicals into water bodies, fueling harmful algal blooms and promoting toxin production by cyanobacteria. Intensified drought periods further increase pollutant concentrations and facilitate the proliferation of invasive or opportunistic species, weakening local biodiversity and destabilizing trophic interactions. These changes collectively threaten aquatic ecosystem services, compromise drinking-water quality, and increase treatment costs, while also posing direct risks to human and animal health through exposure to algal toxins and waterborne pathogens.

This review synthesizes recent findings on the mechanisms by which climate warming is changing freshwater quality and identifies key knowledge gaps. Finally, it outlines adaptive management strategies such as enhanced monitoring networks, watershed-scale nutrient management, restoration of riparian buffers, and controlled flow regimes to mitigate adverse outcomes and enhance the resilience of inland water resources in a warming world.

Keywords: Global warming, lakes, rivers, water quality

INTRODUCTION

Freshwater ecosystems provide drinking water, facilitate food production, and provide the foundation for energy production and biodiversity. Anthropogenic climate change is transforming the hydrology and water quality of lakes and rivers by altering key climatic drivers such as temperature, changes in precipitation patterns, evaporation, snow and glacier melt, and sea level. Intensification of the hydrological cycle (e.g., higher atmospheric humidity and more intense precipitation per degree of warming), earlier snowmelt, and increased terrestrial evaporation are observed with high confidence, along with regionally heterogeneous drying/wetting patterns that shape water quality trajectories through both chronic stresses and extreme events (IPCC WGII). This review integrates mechanistic understanding with recent global syntheses to map how warming alters water temperature regimes, stratification and mixing, oxygen budgets, nutrients, pollutants, and biota, leading to measurable deterioration of water quality indicators and ecosystem services. We highlight the cross-scale interactions between climate forcing, watershed land use, and management (Garrahou et al., 2009; Pershing et. al., 2018; Woolway et al., 2022).

2. Mechanistic Pathways: From Warming to Water Quality

2.1. Thermal Forcing and Lake Stratification

The latest alterations in the global carbon balance and the associated climate tendencies in the thermal and ice dynamics of inland water bodies raise new essential inquiries regarding energy and substance transfer within aquatic systems. Rising air temperatures warm lake surfaces, increase stability, and lengthen stratified periods. Stronger and longer stratification suppresses vertical mixing, reduces oxygen replenishment of bottom waters, and reinforces nutrient and redox stratification. Phenological shifts in onset and breakdown of stratification alter habitat availability and the timing of biogeochemical processes, with cascading effects on primary production and food webs (e.g., trophic mismatches) (Woolway et. al., 2022). Observations and modeling demonstrate earlier stratification onset, prolonged duration, and tendencies toward more frequent and intense lake heatwaves, with clear anthropogenic attribution. Subsurface (metalimnetic/hypolimnetic) heatwaves are also being documented, extending thermal stress below the surface (Woolway et. al., 2021; Kirillin, Shatwell, 2016).

2.2. River Thermal Regimes and Hydroclimatic Extremes

Hydroclimatological dynamics shape river discharge (i.e., streamflow). While numerous interacting factors affect the condition of river ecosystems—such as light availability, thermal regime, nutrient supply, spatial connectivity, biodiversity, and human management—discharge remains a fundamental driver in defining the structural framework of river habitats (Laize et al., 2014). In rivers, warming elevates water temperatures, while droughts and heatwaves reduce flows and dilution capacity; floods increase non-point source loads and resuspension of sediments. A synthesis of global case studies shows that river water quality often worsens during droughts and heatwaves due to higher concentrations of nutrients, organic matter (increased BOD/COD), salinity, and pathogens; floods degrade quality via sediment and pollutant pulses. Multidecadal trends in many basins reflect the combined effects of climate change and intensifying extremes (Vliet et.al., 2023)

2.3. Oxygen Dynamics and Biogeochemical Feedbacks

Warmer water bodies bind less dissolved oxygen (DO), while increased microbial activity, respiration, mineralization, and sediment oxygen demand further reduce DO. In stratified lakes, bottomwater (hypolimnetic) DO declines are common. In many systems, browning (higher dissolved organic carbon (DOC) increases light attenuation and hypolimnetic respiration, increasing oxygen loss, compressing coldwater habitats, and altering ecosystem metabolism (Jane et. al., 2024).

2.4. Nutrients, Internal Loading, and Redox Chemistry

When water oxygen levels decrease or disappear completely, sediments release phosphorus through reductive dissolution of iron oxides, increasing ammonium accumulation; denitrification and anammox alter nitrogen balances. Therefore, stronger and longer stratification with hypolimnetic anoxia increases internal phosphorus load, leading to the risk of eutrophication and harmful algal blooms (HABs) during mixing events and subsequent growing seasons, even when external inputs are reduced (NSTC, 2003; Carpenter, 2005).

2.5. Contaminant Mobilization and Salinity Intrusion

Hydroclimatic extremes regulate pollutant pathways: drought concentrates salts and contaminants; floods transport pesticides, pathogens, pharmaceuticals, and microplastics from catchments; sea-level rise promotes salinity intrusion into tidally influenced rivers, threatening drinking-water intakes. The thawing of permafrost and watershed browning mobilize metals and organic carbon, altering acidity and ionic composition in Arctic and mountainous systems (Byl et, al., 2025).

3. Lakes: Warming, Deoxygenation, and Eutrophication

3.1. Lake Heatwaves and Attributed Change

Lake heatwaves extended intervals of anomalously warm surface water are becoming more frequent, longer, and more intense. Recorded ecological impacts include mass fish mortalities, shifts in plankton phenology and metabolism, and altered food-web structure. Detection–attribution studies link severe lake heatwaves to anthropogenic warming. Subsurface heatwaves in the metalimnion and hypolimnion are increasingly reported, extending thermal stress into deeper aquatic zones (Woolway et al., 2025).

3.2. Widespread Deoxygenation and Habitat Squeeze

Sustained monitoring reveals broad DO decrease in many temperate lakes, driven by warming and stratification effects. Simultaneously, increased terrestrial inputs (browning) intensify hypolimnetic oxygen demand. The net effect is habitat squeeze for cold-water taxa such as salmonids and coregonids as cool, oxygenated waters contract. In many lakes, browning-induced oxygen loss outpaces any surface-cooling benefits for habitat, raising biodiversity risks (Jane et. al., 2024).

3.3. Harmful Algal Blooms (HABs) and Toxin Risks

Climate change interacts with nutrient enrichment to increase HAB frequency, duration, and toxicity. Modeling for large reservoirs projects substantial increases in cyanobacterial biomass under plausible warming and stratification scenarios—even with constant nutrient inputs—highlighting the synergism of warming and eutrophication. Treatment plants face challenges related to toxins, taste and odor, and disinfection by-products (Chapra et al., 2017). Climate change and nutrient dynamics influence each other both directly and indirectly. Rising temperatures clearly alter the habitats suitable for harmful algal blooms (HABs). Additionally, climate shifts can drive the expansion of harmful algal species by modifying precipitation patterns—leading in some regions to more frequent droughts, and in others to increased intensity or frequency of storms. Such episodic storm events and broader climate variability impact freshwater flow timing, water residence periods, the scale and timing of nutrient inputs, and the subsequent biological responses (Heisler et al., 2008).

4. Rivers: Flow Regimes, Extremes, and Quality

4.1. Droughts and Heatwaves

During droughts and heat waves, low flows increase residence times, temperatures, and concentrations of nutrients, salts, and pathogens. As dilution decreases, point source contributions increase. Biological oxygen demand increases while DO decreases, stressing the biota and creating treatment challenges for utilities. Observational syntheses indicate that water quality deteriorates under such extremes in the majority of cases (Vilet et al., 2023).

4.2. Salinity Intrusion and Heat Stress in Regulated Rivers

In tidal rivers and deltas, sea level rise and drought are advancing salt fronts, threatening water intakes and altering ionic composition. Active reservoir releases and temporary barriers are increasingly being used to control salinity intrusion, demonstrating the interactions of climate risk across water supply and estuary management (Byl et al., 2025).

5. Water Quality Constituents and Processes

5.1. Temperature and Dissolved Oxygen

Direct thermal effects reduce oxygen solubility. Indirect effects (higher respiration, nitrification and denitrification rates, and sediment oxygen demand) further deplete DO. Under low oxygen levels or anoxia, reduced compounds (NH_4^+ , Fe^{2+} , Mn^{2+} , H_2S) accumulate, and emissions of methane (CH_4) and nitrous oxide (N_2O) may increase. (Naqvi et. al., 2010).

5.2. Nutrients (Nitrogen and Phosphorus)

Rising temperatures stimulate cyanobacterial blooms and nitrogen-fixing capacity in some species; redox-driven sediment processes increase phosphorus release under oxygen-depleted conditions, while storm events introduce significant external nutrient inputs. Internal nutrient recycling maintains eutrophic conditions even after external inputs have diminished, highlighting the need for long-term, multifaceted restoration approaches (Nürnberg 2024).

5.3. Contaminants and Pathogens

Extreme events mobilize legacy metals, pesticides, and emerging contaminants (pharmaceuticals, PFAS, microplastics), while warm, nutrient-rich waters favor pathogenic bacteria such as *Vibrio* and *E. coli*. Permafrost thaw enhances delivery of DOC and metals to high-latitude rivers and lakes, modifying acidity and redox state with visible ecosystem consequences. The distribution of pathogens and the incidence of waterborne disease outbreaks are closely linked to environmental and climatic conditions. Global climate change will affect the hydrological cycle in many different ways that will influence waterborne pathogen survival, infectivity and distribution (Nicholas, 2014).

6. Ecological and Health Consequences

Thermal habitat loss and hypoxia reduce niche availability for coldwater and stenothermic species, restructure plankton communities, and increase fish mortality risks during heatwaves and turnover events. Browning and deoxygenation compress vertical habitat, leading to mismatches in predator-prey dynamics (Jane et al., 2024).

HAB toxins (microcystins, anatoxins, cylindrical spermopsin) pose a threat to drinking water safety and recreation; storm-related increases in microbial indicators and pathogens complicate treatment. Warmer waters extend seasonal ranges for some pathogens, requiring more intensive monitoring and risk communication (Elidrissi et al., 2024).

CONCLUSION

Global warming is degrading the water quality of lakes and rivers through thermal, hydrological, biogeochemical, and microbiological pathways. Lakes are experiencing increasingly severe and prolonged stratification, heat waves, and bottom-water anoxic conditions, which increase nutrient loading and the risk of HABs, threatening the health of organisms. Rivers are experiencing quality degradation reflecting changes in pollutant dilution, mobilization, and transformation during droughts, heat waves, and floods. These dynamics threaten ecosystems, human health, and economies; however, targeted adaptation (load reduction, nature-based solutions, and dynamic operations) and robust monitoring and forecasting can significantly reduce these risks. Aligning climate change mitigation with water quality management is crucial for maintaining freshwater security throughout the 21st century.

ABSTRACT

Despite its widespread use in the fertilizer and chemical industries, dilute nitric acid (NA) can cause significant operational and material integrity problems due to chloride contamination. Chloride ions, in particular, can lead to pitting and stress corrosion cracking (SCC) in stainless steel equipment, thereby reducing the service life of industrial facilities

In this study, potential sources of chloride contamination in dilute nitric acid production were identified, and the measures taken to control them were evaluated. The sources of chloride include:

Feed water: residues in inadequately treated water,

Raw material purity: ammonia and other auxiliary chemicals,

Cleaning agents and sealing materials used in process equipment,

Intermediate species: e.g., nitrosyl chloride (NOCl)

Analyses conducted by TSE Ankara Chemical Laboratory initially measured chloride levels at approximately 74 ppm, with historical data ranging from 70 to 300 ppm. These levels are significantly above the literature-recommended safe limit of <5–10 ppm, posing a serious corrosion risk.

As part of process improvements, measures such as modernization of water treatment systems, replacement of equipment materials, and control of NOCl formation were implemented. Additionally, controlled purge operations in critical circuits were employed to prevent chloride accumulation. Field analyses conducted after these improvements showed that chloride levels remained below 10 ppm over a 30-day monitoring period, even with the adjacent KNO₃ production unit in operation, staying well within safe limits.

These findings are consistent with approaches recommended in the literature (purge operations, water treatment, intermediate species control), confirming that purge is the most effective strategy to control chloride contamination in large-scale industrial facilities.

Keywords; Nitric Acid, Chlorine Contamination, NOCl, Corrosion, Product Purity.

INTRODUCTION

Nitric acid is a strong mineral acid primarily used in the production of nitrate fertilizers and various chemical products. It constitutes a critical input in modern agricultural systems, significantly enhancing crop productivity (Thiemann et al., 2021). The world's population reaching 8 billion would not have been possible without the development of the fertilizer industry (Randive et al., 2021). Nitric acid, due to its high nitrogen content (15.5–34.5%) and rapid availability to plants, serves as an essential feedstock for nitrogen-based fertilizers alongside ammonia. Currently, approximately 80% of global nitric acid production is dedicated to fertilizer manufacturing (Smil, 2004).

Industrially, nitric acid (HNO_3) is a key inorganic compound widely used in the production of explosives, dyes, organic chemicals, plastics, and numerous other products. Highly concentrated nitric acid (95–99%) is preferred in intensive chemical processes, whereas dilute nitric acid (20–68%) is commonly employed in applications where material compatibility and controlled reactivity are critical.

One of the most significant operational challenges in nitric acid production plants is corrosion, which can reduce equipment lifespan and lead to unplanned shutdowns. Process design strategies must therefore include green hydrogen production via electrolysis or solar-powered thermochemical cycles, as well as the supply of highly pure nitrogen with oxygen impurities below 10 ppm to prevent catalyst deactivation in the subsequent Haber–Bosch process (Budama et al., 2022; Moghaddam and Krewer, 2020).

Chlorine contamination, particularly problematic in the health and food sectors, is a major factor accelerating corrosion in production facilities. Chlorine reacts with organic compounds (e.g., humic and fulvic acids) and inorganic species (e.g., ammonia) accumulated in wash tanks, thereby trapping free chlorine (Simpson and Mitch, 2021). High chloride ion concentrations can damage stainless steel and alloys used in nitric acid plants, leading to pitting and stress corrosion cracking, which severely reduces equipment lifespan. Therefore, chlorine contamination must be closely monitored and minimized to ensure operational reliability and extend equipment service life.

MATERIAL AND METHOD

This review evaluates chloride contamination in dilute nitric acid production by focusing on:

- 1.Sources (feed air, cooling water, raw materials, corrosion products),
- 2.Removal methods (purge, gas-phase treatment, ion-exchange resins, chemical additives),
- 3.Reaction mechanisms ($\text{Cl}^- \rightarrow \text{HCl}$, Cl_2 formation, NO_2 oxidation),
- 4.Industrial practice (purge as the primary method in large-scale facilities).

Key references include Wilkinson (1961), Spence (2011), Kurley et al. (2019), Roux et al. (2019), Li et al. (2022), Wang et al. (2020).

Sources:

Chloride ions originate mainly from marine aerosols, cooling water, low-purity raw materials, and corrosion-derived leaching.

Removal Methods:

-Purge operations limit chloride accumulation by continuously withdrawing a fraction of low-concentration acid streams.

-Gas-phase oxidation converts Cl^- ions into Cl_2 through NO_2 -mediated oxidation, facilitating their removal in the purge gas stream.

-Ion-exchange resins are applied in specialized production lines but are economically unfeasible for large-scale plants.

-Chemical additives (NaNO_3 , KNO_3) mitigate corrosion but do not remove chloride from the system.

Reaction Mechanisms:

1.Oxidation of chloride ions to chlorine gas:

2.Overall reaction in nitric acid production involving NO_2 and water:

These mechanisms describe the oxidation of chloride ions and their volatilization into the gas phase.

Industrial Application in Our Facility:

In our nitric acid production facility, we regularly implement purge operations. Controlled side-stream withdrawal from critical circuits ensures that chloride concentrations remain below critical thresholds, effectively minimizing corrosion risk and extending equipment life.

Figure 2. Most accepted mechanism Nitrosyl chloride (NOCl) : N=O-Cl

Figure 2. Most accepted mechanism Nitrosyl chloride (NOCl) : N=O-Cl

RESULTS AND DISCUSSION

Field analyses were conducted over a period of 30 consecutive working days at 09:00 AM. Samples were collected from multiple critical points within the nitric acid production system, including OksiA, OksiB, AOS, Basic Condensate, and Production Acid streams. The results demonstrated a consistent and gradual decrease in chloride concentrations over time, indicating the effectiveness of the purge operations and other process improvements implemented in our facility for controlling chloride contamination.

To assess potential cross-contamination, comparative sampling was performed while the adjacent KNO_3 production facility was both operational and non-operational. The data showed that even when the KNO_3 unit was active, chloride levels in our nitric acid circuits remained below critical thresholds, confirming that the purge strategy effectively mitigates contamination risks. These findings are consistent with literature reports emphasizing the importance of controlled side-stream withdrawal and purge operations in maintaining low chloride concentrations and minimizing corrosion in large-scale nitric acid plants (Wilkinson, 1961; Roux et al., 2019; Zhang et al., 2018).

The observed reduction in chloride levels also aligns with previous studies on the role of water treatment, equipment material selection, and intermediate species control (e.g., NOCl) in limiting chloride accumulation and volatilization (Kurley et al., 2019; Wang et al., 2020). Collectively, these results demonstrate that the combination of purge operations and process optimization provides an effective strategy to enhance equipment lifespan and operational reliability in industrial nitric acid production.

Table 1. Chloride Analysis in Nitric Acid (Measurements Taken While the Potassium Nitrate Facility Was Non-Operational and Purge Operations Were Applied)

Table 2. Chloride Analysis in Nitric Acid (Measurements Taken While the Potassium Nitrate Facility Operational and Purge Operations Were Applied)

CONCLUSIONS

This study confirms that chlorine contamination in dilute nitric acid production is a multifactorial issue. Initial analyses conducted at the TSE laboratory indicated chlorine levels of approximately 74 ppm, with historical data showing values reaching up to 300 ppm, posing significant corrosion risks. Literature reports emphasize that high chloride concentrations in nitric acid plants can cause pitting and stress corrosion cracking in stainless steel and alloys (Spence, 2011; Li et al., 2022; Kurley et al., 2019).

Targeted process improvements implemented in our facility included the modernization of water treatment systems, raw material control, equipment upgrades, and suppression of NOCl formation. As a result, field data demonstrated that chloride levels dropped below 10 ppm. Furthermore, even when the adjacent KNO₃ production unit was operational, chloride concentrations remained below critical thresholds, confirming the effective mitigation of cross-contamination risks.

These findings are consistent with literature recommendations indicating that purge operations, water treatment, and intermediate species control are effective strategies to minimize corrosion in nitric acid production plants (Wilkinson, 1961; Roux et al., 2019; Zhang et al., 2018; Wang et al., 2020). However, to ensure long-term operational reliability, continuous monitoring and further process refinements are necessary.

In conclusion, this study demonstrates that an integrated approach can be successfully applied in dilute nitric acid production facilities to minimize corrosion and extend equipment lifespan.

ABSTRACT

The integration of organic fertilizers into horticultural systems has gained increasing importance as a sustainable strategy to enhance soil fertility and crop productivity under challenging soil conditions. This study aimed to evaluate the effects of various organic fertilizers including manures from small ruminants, cattle, poultry, and vermicompost on the chemical properties of a sandy-calcareous soil and the growth performance of melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.). The study focused on how recommended fertilizer doses influence soil chemical quality and plant growth. The results indicated that organic fertilization altered soil electrical conductivity (EC) and available phosphorus (P) levels. Poultry and cattle manures led to notable improvements in soil nutrient content. Additionally, plant growth parameters such as stem diameter and fruit weight were positively affected by organic fertilizers, particularly poultry manure. Crop-specific responses were observed: melon plots exhibited higher soil EC and available P, while watermelon plants showed superior performance in stem diameter, fruit flesh thickness, and soluble solid content. In contrast, melon plants recorded higher chlorophyll levels. Overall, poultry manure emerged as the most effective input for enhancing plant growth, while vermicompost and cattle manure also contributed depending on the crop type. These results suggest that organic fertilizers, especially poultry manure, are valuable tools for improving soil fertility and crop productivity in calcareous soils.

Keywords: Calcareous soils, Fruit quality, Mediterranean climate, Organic amendments

INTRODUCTION

Sustainable agricultural systems are an emerging model that promotes the integrated use of organic materials as alternatives to chemical inputs are being developed to ensure more environmentally friendly and efficient food production. In this context, organic fertilizers that enhance soil fertility have come to the forefront. The core component of organic fertilizers, organic matter, serves as a primary source of energy and nutrients for soil-dwelling microorganisms. However, in Turkey and many other agricultural countries, inadequately matured animal manures characterized by high C/N ratios and the presence of root rot pathogens or weed seeds have long been used in crop production. These manures often fail to provide the expected agronomic benefits for both soil and plants (Karaman 2012).

In recent years, there has been a growing demand particularly in intensively cultivated horticultural and greenhouse production areas for thermally treated or fermented organic fertilizers. This trend reflects efforts to promote sustainable agriculture and to optimize the combined use of organic and chemical fertilizers. Nevertheless, these processed fertilizers are significantly more expensive than traditionally matured manures, due to additional processing, packaging, registration, and storage costs. Furthermore, their claimed benefits for practical use often rely more on manufacturer assertions than on robust scientific evidence. Therefore, it is essential to evaluate their effects on soil fertility and plant growth in order to better understand their potential contribution to sustainable agricultural systems and to promote their effective and economical use.

Melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.), among the most widely produced and consumed vegetables globally and in Turkey, are annual crops adapted to warm and temperate climates. While both crops are cultivated in open fields and greenhouses, only about 3% of melon and 2% of watermelon production is conducted under protected cultivation (Anonymous 2001; Taşkaya and Keskin 2004). These crops are valued not only for their edible parts but also for their seeds and rinds, which are utilized across the food, pharmaceutical, and cosmetic industries, making them strategic export commodities. Deep, well-drained, sandy-loam or loamy-sand soils with high water-holding capacity are ideal for watermelon cultivation, while poorly drained soils with shallow groundwater levels (below 1 meter) are unsuitable (Tuna and Özer 2005). Like many other cultivated plants, melons and watermelons respond positively to organic fertilization. Accordingly, the application of solid and/or organic fertilizers in the cultivation of these crops is considered important for improving both yield and quality, as well as enhancing soil health (Bayram et al. 2020).

In this study, the effects of processed organic fertilizers including sheep, cattle, and poultry manures, as well as vermicompost on the chemical properties of calcareous sandy soils and on plant growth in melon and watermelon cultivation were investigated. Additionally, the study aimed to assess how the optimum application rates recommended by organic fertilizer manufacturers for plant growth influence soil fertility. By comparing the effects of these commonly used organic fertilizers on both soil chemical parameters and plant growth indicators, this study identified the strengths and weaknesses of each fertilizer type. The findings offer valuable insights into the practical use of organic fertilizers in sustainable farming systems.

MATERIAL AND METHODS

Site Description

This study was conducted as a field trial at the Finike campus of Akdeniz University (36°18'31"N, 30°08'48"E; altitude: 40 m). According to meteorological data collected during the trial period, the site had an average daily temperature of 19.3 °C, an average daily sunshine duration of 9.10 hours, an average daily open surface evaporation of 125.58 mm, an average daily rainfall of 1.4 mm, an average daily wind speed of 1.6 m/sec, and an average relative humidity of 66.03%.

Soil samples collected to represent the trial area were analyzed prior to the experiment. The soil was classified as sandy loam in texture. It had a neutral pH and was classified as non-saline. The soil also contained a high level of lime and was rated as sufficient in terms of humus content. Total nitrogen (N) and available phosphorus (P) levels were determined to be adequate, while the cation exchange capacity (CEC) was classified as low.

Organic Fertilizers and Fertilization Practices

In this trial, various heat-treated organic fertilizers (processed at 65–70 °C) were applied, including small ruminant manure (goat and sheep manure; T1), cattle manure (T5), poultry manure (T4), and vermicompost (T2) (Table 1). Additionally, control (T3) plots were established, which received only chemical fertilizers (detailed below) without any organic fertilizer input. The application rates of the organic fertilizers were determined based on the manufacturers' recommendations and supported by findings from previous studies (Maltaş 2023; Maltaş et al. 2024). This approach aims to develop practical organic fertilization strategies suitable for field conditions, specifically for melon and watermelon cultivation, while improving soil chemical properties and supporting plant growth.

Table 1. Some properties of organic fertilizers used in the experiment

Parameter	Organic fertilizer			
	Vermicompost	Chicken manure	Cow manure	Goat-sheep manure
Organic matter, %	45	62	35	70
EC (dS/m)	6.0	2.6	11.2	7.5
Organic C, %	26.1	35.96	20.3	40.6
Humic/fulvic acid, %	41.5	36	15	28
Total N, %	3.0	2.2	1	1.5
Total P, %	1.5	1.76	1.5	1.5
Total K, %	1.0	1.62	-	2
Humidity max., %	20	20	20	20
pH	6-8	6.2	7-9	8-10
C/N	9/1	16/1	20/1	27/1
C/P	17/1	20/1	13/1	27/1

The application rates were as follows: 4 Mg ha⁻¹ for vermicompost, 8 Mg ha⁻¹ for cattle manure, 6 Mg ha⁻¹ for goat manure, and 4 Mg ha⁻¹ for poultry manure. In addition to these inputs, chemical fertilizers certified for use in organic farming were applied through a drip irrigation system to support plant nutrition throughout the experimental period. These chemical inputs were selected based on the initial soil analysis and estimates of nutrient removal by the crops (Zengin 2023).

Previous studies have demonstrated that the use of organic mulching materials (such as straw, sawdust, and compost) can improve microclimatic conditions and enhance the

effectiveness of organic fertilizers (Gao et al. 2019; Teasdale and Mohler 2000). Mulching has been shown to promote soil biological activity, thereby improving nutrient uptake efficiency by plants and contributing to sustainable farming practices (Li et al. 2019). Therefore, in this study, a mulch was applied to the experimental plots to maximize the effectiveness of organic fertilizers.

Implementation of the Experiment

In this study, melon and watermelon cultivation was carried out using four types of heat-treated organic fertilizers. The experimental setup was established according to a randomized block design with three replications. The organic fertilizers were applied uniformly to the plots based on their respective application rates (in dry weight).

Melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.) seedlings were procured from a commercial nursery. Melon seedlings (Anka F1) were transplanted at a spacing of 2.0 m between rows and 0.3 m within rows, while watermelon seedlings (Peykan F1) were planted at 2.0 m between rows and 0.6 m within rows. Both crops were cultivated over a vegetation period of approximately 90–100 days.

Throughout the growing period, all essential cultural practices such as weed control, hoeing, and plant protection treatments were carried out. In addition, irrigation and fertigation were performed using a drip irrigation system. The daily irrigation requirements of the plants were calculated based on climatic parameters (including rainfall, temperature, and relative humidity), soil texture and moisture, and plant needs (e.g., signs of wilting). These water requirements were integrated with the optimized fertilization strategy to ensure proper crop management.

Sampling and Analysis

Soil samples were air-dried and sieved through a 2 mm mesh prior to analysis. To characterize the initial soil conditions, samples were collected from the 0–30 cm soil depth using an auger before the experiment began. These samples were analyzed for texture, pH, electrical conductivity (EC), lime content, organic matter, total nitrogen (N), available phosphorus (P), and cation exchange capacity (CEC). Additionally, to evaluate the effects of organic fertilizer applications on soil chemical properties, samples collected at harvest were analyzed again for organic matter, total nitrogen, available phosphorus, and CEC.

The methods used for analyzing the above-mentioned soil parameters were as follows: soil texture was determined using the hydrometer method (Bouyoucos 1955); pH and EC were measured in a 1:2.5 soil-to-water suspension (Jackson 1967; Anonymous 1982); lime content was determined using the calcimeter method (Çağlar 1949); organic matter was measured using the modified Walkley-Black method (Black 1965); total nitrogen was determined using the Kjeldahl method (Kacar 1995); available phosphorus was analyzed according to the Olsen method (Olsen and Sommers 1982); and CEC was determined using the ammonium acetate method (Kacar 1995).

At the end of the experiment, pomological and physiological traits were assessed in plant and fruit samples (Figure 1 and Figure 2). For each treatment replication, measurements and evaluations were performed on three randomly selected plants per plot. The results were expressed as the average of these three plants.

Figure 1. Views of selected physiological and pomological traits in watermelon plants (A: Soluble solids content, B: Chlorophyll content, C: Fruit flesh thickness, D: Stem base diameter, E: Fruit juice pH, F: Fruit weight)

Figure 2. Views of selected physiological and pomological traits in watermelon plants (A, C: Harvested fruits; B: Fruit juice pH)

The evaluated pomological characteristics included: stem base diameter (cm; measured with a caliper), fruit fresh weight (g; measured with a precision balance), and yield (kg da^{-1} ; calculated). The physiological parameters included: soluble solids content (SSC), fruit juice pH, total chlorophyll content (measured with a chlorophyll meter), and rind thickness (mm; measured with a caliper).

Statistical Analyses

The numerical data obtained in this study were statistically analyzed using the SPSS 23.0 software package. The significance levels of soil chemical properties and plant pomological and physiological parameters were determined through analysis of variance (ANOVA) at the 5% significance level. Parameters showing statistically significant differences were further evaluated using Duncan's multiple range test for mean separation. In addition, Pearson correlation analysis was performed to determine the relationships among the measured parameters (SPSS 2008).

RESULTS AND DISCUSSION

Soil Chemical Properties

At the end of the growing season, the effects of different organic fertilizer treatments on soil cation exchange capacity (CEC), organic matter (OM) content, total nitrogen (N%), and available phosphorus (P, mg/kg) were evaluated for watermelon cultivation (Table 2). According to the statistical analysis, changes in CEC, total N, OM (%), and available P values in watermelon plots were found to be statistically non-significant.

Table 2. Effects of applications on CEC, OM, total N and available P contents in watermelon soil

Treatments	CEC (meq/100)	% OM	% N	P (mg/kg)
T1	26.54	2.26	0.16	22.17
T2	29.33	2	0.15	19.47
T3	31.04	2.1	0.16	13.36
T4	28.11	2.17	0.18	18.52
T5	30.58	1.92	0.18	38.54
ANOVA (%5)	NS ¹	NS	NS	NS

¹ NS; not significant.

In contrast, in melon cultivation plots, although changes in CEC, total N, and OM (%) were also statistically non-significant, the variation in available phosphorus content was statistically significant at the $P < 0.05$ level (Table 3). Among the treatments, T4 (48.60 mg/kg) resulted in the highest increase in available phosphorus content compared to the other applications.

Table 3. Effects of applications on CEC, OM, total N and available P contents in melon soil

Treatments	CEC (meq/100)	% OM	% N	P (mg/kg)
T1	32.82	2.29	0.15	13.31 b ¹

T5	29.68	2.00	0.17	40.04 ab
ANOVA (%5)	NS	NS	NS ³	2.966 ** ²

¹ Differences between values not indicated by the same letter are significant at the 5% level. ² **, significant at the 1% level. ³ NS; not significant.

Previous studies have indicated that increasing doses of poultry manure significantly contribute to the enhancement of soil nitrogen content (Okur et al. 2008), while farmyard manure has been found to have a more pronounced effect on available phosphorus levels in soils (Agbenin and Goladi 1997). In the present study, the available phosphorus level in soils under melon cultivation (T4: 48.60 mg/kg) was approximately 20% higher than that in watermelon soils.

Göksu and Kuzucu (2017), in their study investigating the effects of different vermicompost doses on yield and quality parameters in watermelon, reported that vermicompost and chemical fertilizer applications increased the soil ion exchange capacity. However, in the current study, organic fertilizer treatments did not result in statistically significant changes in CEC for either melon or watermelon soils.

Similarly, Kılıç and Sönmez (2019), in their study on the effects of increasing doses of various organic materials (vermicompost, poultry manure, farmyard manure, leonardite) on soil fertility parameters in lettuce cultivation, found that the effects on soil organic matter content were statistically significant. In contrast, the findings of the current study showed that different organic matter applications had no statistically significant effect on soil organic matter levels in either melon or watermelon cultivation.

Plant Growth Properties

At the end of the cultivation period, among the yield and quality parameters obtained from the watermelon plant, leaf chlorophyll content (SPAD), fruit flesh thickness, fruit juice pH, and soluble solid content were found to be statistically non-significant (Table 4). However, collar diameter was found to be statistically significant at the $P < 0.01$ level, with higher values observed in T1 and T4 (23.41 mm and 23.23 mm, respectively) compared to other treatments. Fruit weight was also found to be statistically significant at the $P < 0.05$ level, with higher fruit weights recorded in T2, T4, and T5 (7.38 kg, 8.13 kg, and 7.52 kg, respectively).

Table 4. Effects of treatments on SPAD, root collar diameter (RCD), fruit weight (FW), fruit flesh thickness (FFT), fruit juice pH (FJpH) and soluble solid content (SSC) in watermelon

Treatments	SPAD	RCA (mm)	FW (kg)	FFT (cm)	FJpH	SSC

Regarding the melon plant, leaf chlorophyll content (SPAD), fruit flesh thickness, fruit juice pH, and soluble solid content were also found to be statistically non-significant (Table 5). However, root collar diameter was found to be statistically significant at the $P < 0.05$ level, with higher values observed in T1, T3, and T4 (14.67 mm, 14.83 mm, and 14.85 mm, respectively). Fruit weight was found to be statistically significant at the $P < 0.01$ level, with the highest fruit weight observed in T1 (2.02 kg).

Table 5. Effects of treatments on SPAD, root collar diameter (RCD), fruit weight (FW), fruit flesh thickness (FFT), fruit juice pH (FJpH) and soluble solid content (SSC) in melon

Treatments	SPAD	RCA (mm)	FW (kg)	FFT (cm)	FJpH	SSC

Üçok et al. (2019), in their study investigating the effects of different organic fertilizer applications on yield, quality, and plant nutrient contents in lettuce (*Lactuca sativa* L. var. *crispa*), reported no significant differences in chlorophyll content among the treatments. Similarly, in our study, although the differences between applications were not statistically significant for both watermelon and melon plants, the chlorophyll value in melon was found to be approximately 20% higher than in watermelon.

Özen (2018) investigated the effects of different doses of mushroom compost, leonardite, and vermicompost on lettuce yield and quality, and reported that increasing doses of organic material applications resulted in increased collar diameter. In a study conducted on watermelon (*Citrullus lanatus* (Thunb.) Matsum & Nakai), it was reported that different doses of vermicompost (0, 300, and 600 kg/da) did not have statistically significant effects on fruit flesh thickness, fruit juice pH, and soluble solid content (Göksu and Kuzucu 2017). Similarly, in our study, although the differences between treatments were not statistically significant in both watermelon and melon, the collar diameter, fruit flesh thickness, and soluble solid content in watermelon were found to be 40%, 40%, and 100% higher, respectively, compared to melon. In addition, the fruit weight of watermelon was found to be six times higher than that of melon. One of the main reasons for this large difference is the physiologically larger fruit size of watermelon compared to melon.

Correlations Between Soil Properties and Plant Growth

Based on the numerical data obtained from the trial, relationships between soil chemical properties and plant growth parameters were examined. Accordingly, in melon soils, a negative correlation was observed between fruit flesh thickness and organic matter content ($r = -0.539^*$), while a positive correlation was found between root collar diameter and organic matter content ($r = 0.728^{**}$). These correlations suggest that soil organic matter may play a dual role in influencing plant morphological traits. While the positive correlation between root collar diameter and organic matter content implies a supportive role of soil organic matter in promoting vegetative growth and stem development, the negative correlation between fruit flesh thickness and organic matter content might indicate a potential trade-off between vegetative and reproductive growth processes under certain soil conditions. This could be due to nutrient partitioning or changes in water-holding capacity and aeration associated with increased organic matter. However, these relationships are likely to be influenced by plant species, growth stage, and environmental factors.

CONCLUSION

This study aimed to evaluate the effects of various organic fertilizers including manures from small ruminants, cattle, poultry, and vermicompost on the chemical properties of a sandy-calcareous soil and the growth performance of melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.). The study focused on how recommended fertilizer doses influence soil chemical quality and plant growth. Poultry and cattle manures stood out in improving soil chemical properties in watermelon cultivation areas, whereas vermicompost and poultry manure significantly enhanced plant growth parameters. For melon cultivation, cattle manure was most effective for soil chemical improvements, while small ruminant, poultry, and cattle manures showed prominent positive effects on plant development. Overall, poultry manure emerged as the most effective input for enhancing plant growth, while vermicompost and cattle manure also contributed depending on the crop type. These results suggest that organic fertilizers, especially poultry manure, are valuable tools for improving soil fertility and crop productivity in calcareous soils. Nonetheless, expanding these findings through comprehensive studies involving different crops, soil types, cultivation locations, and production systems (e.g., greenhouse or organic farming) will be essential to deepen understanding and broaden the applicability of these organic fertilization strategies. These results underscore the critical role of optimized organic fertilization in promoting sustainable agricultural productivity, supporting both soil health and crop performance in Mediterranean agroecosystems.

ABSTRACT

Owing to its beneficial impact on human health and its abundance of essential nutrients, the walnut is considered one of the most nutritionally valuable tree nuts. This study's objective was to find SNPs related to potassium (K) and sodium (Na) accumulations in walnut fruits collected in 2021 and 2022 from a population of 154 different walnut genotypes, using the GWAS method. It was observed that K concentrations ranged from 131.75 mg/100g to 850.00 mg/100g, while Na concentrations varied between 2.00 mg/100g and 84.50 mg/100g. The genotypes exhibited a statistically significant impact on both nutrient elements, according to variance analysis (p -value ≤ 0.01). The concentrations of K and Na exhibited high heritability estimates, both recorded at 0.99. 13,611 clean SNPs and the MLM (PCA+K) approach were used GWAS analysis and a total of 17 significant associations were identified (16 for K and 1 for Na). Of the 16 significant SNPs identified for K, 14 were found in both years. Additionally, the SNP identified for Na was consistent for both years. For the investigation of potential candidate genes, 17 SNP sequences were aligned with the *Juglans regia* genome, and potential candidate genes were detected. It was discovered that thirteen of these SNPs match onto particular chromosomes in the walnut genome. For the SNPs related to K accumulation, 118 candidate genes in all were found. For the SNP marker related to Na accumulation, 18 candidate genes were detected. The findings obtained from our study suggest that the SNPs related to K and Na accumulation in walnut fruit, along with the candidate genes related to these SNPs, could contribute to marker-assisted selection applications in future walnut breeding efforts and plant breeding studies using genetic engineering approaches.

Keywords Walnut, GWAS, SNP, potassium, sodium, plant-based nutrition

INTRODUCTION

Juglans regia L. ($2n = 32$, nearly 606 Mb per 1C genome), known as walnut and *J. regia* L. is a monoecious, dichogamous, typically cultivated in temperate regions, pollinated by wind, possessing kernels with very high nutritional value, and a long-lived tree species belonging to the Juglandaceae family (Zhu et al., 2015; Akca et al., 2015; Delaviz et al., 2017). The walnut is widely grown around the world and has significant commercial value because of its high nutritious content and high-quality wood (Ozcan et al., 2010; Gupta et al., 2019). In walnut production, the leading countries worldwide are China, The United States, Iran, Turkey, Ukraine, France, and India, respectively (Taha and Al-wadaan, 2011; Orman et al., 2020).

Walnut stands out as a medically intriguing and promising natural food, owing to its highly valuable nutritional composition that benefits human health (Taha and Al-wadaan, 2011; Liu et al., 2020). Diverse components of the walnut, including its kernel, blossoms, leaves, green husk, and oil, exhibit distinct pharmacological qualities and are utilized in the management of diabetes, rheumatic pain, dementia and Alzheimer's, malaria, and dermatological conditions (Delaviz et al., 2017; Gupta et al., 2019).

Previous studies have determined the macro-nutrient elements in walnuts as potassium (K), phosphorus (P), calcium (Ca), magnesium (Mg), and sodium (Na) (Muradoglu et al., 2010). The recommended daily intake is about 3.5 grams for K and 3.0 grams for Na. K is essential for preserving acid-base equilibrium, sending neural signals, and managing cell membrane functions, while Na is necessary for regulating and maintaining acid-base balance, ensuring cell permeability, and facilitating the absorption of bile salts (Soetan et al., 2010; Zoroddu et al., 2019). Macronutrients are also essential for plant growth, development, and the maintenance of vital activities. K plays a role in maintaining tissue turgor pressure, regulating the opening and closing of stomata, and controlling osmotic pressure in plant cells, while Na performs key functions such as regulating turgor pressure and cell expansion (Fageria, 2001; Raddatz et al., 2020).

Recently, plant-based nutrition has become popular worldwide due to its economic affordability, and health benefits (Suliburska et al., 2012; Sharma et al., 2023). The macro- and micro-nutrient content of commonly consumed plants can be rapidly and precisely improved through genetic biofortification. This process involves identifying genomic regions that affect nutrient content, developing SNP markers via genotyping-by-sequencing (GBS), mapping quantitative trait loci (QTL), and creating DNA-based molecular markers using Diversity Array Technology (DArT) (Orman and Ok, 2016; Gupta et al., 2020; Koc et al., 2022; Sharma et al., 2023).

The "Genome-Wide Association Studies (GWAS)" technique is used for mapping quantitative characteristics based on linkage disequilibrium (LD) in genetically diverse individuals of the same species and for elucidating the relationship between DNA markers and phenotypic traits (Uffelmann et al., 2021). There are GWAS studies on shell color and characteristics, phenology, and the accumulation of nutrient elements such as iron (Fe), manganese (Mn), calcium (Ca), and phosphorus (P) in walnuts (Arab et al., 2019; Orman et al., 2020; Bernard et al., 2020; Akpunar et al., 2024; Doganay et al., 2025). The aim of this study is to determine the K and Na concentrations in walnut kernels obtained from 154 different genotypes and to identify the genes associated with these concentrations using the GWAS method. This study is significant as it is the first association mapping study to identify both the K and Na concentrations in walnut fruit and the genes controlling these concentrations using the GWAS method.

MATERIALS AND METHODS

Plant materials

A walnut population comprised of 154 distinct walnut genotypes was cultivated in the Genetic Resources Parcels of the Yalova Atatürk Central Horticultural Research Institute (ABKMAE). Information about these varieties is presented in **Table S1**.

Determination of potassium (K) and sodium (Na) concentrations in walnut kernels

The concentrations of K and Na in 154 different walnut genotypes were measured using the method developed by Kacar and İnal (1972) (Kacar and Inal, 1972). To obtain more reliable and consistent results, all analysis procedures were performed in triplicate for each element from each genotype.

Variance analysis

To determine the statistical significance of the effects of replication (R), genotype (G), year (Y), and Y x G interactions on K and Na concentrations in 154 walnut genotypes, a two-way analysis of variance (ANOVA) was conducted using the SPSS (Statistical Package for the Social Sciences) software program (version 12.0J; SPSS Inc., Chicago, IL, USA). Year and genotype interactions were viewed as constant effects in the analysis of variance, whereas K and Na accumulation values were viewed as response variables and replications as random factors. The variance analysis was carried out at significance levels of 5% and 1%. Additionally, heritability (H^2) values were calculated to evaluate the effect of the genetic component on the concentrations of both dietary elements (Lamichhanea et al., 2021; Sary et al., 2022).

Genotypic data

The raw SNP dataset produced by Orman et al. (2020) using the DArT genotyping approach provided the genotypic data used in this investigation (Orman et al., 2020). To improve data quality, SNPs with a call rate below 80% were removed from the raw SNP dataset containing 16,774 SNPs. The genotypic data used in this study consisted of the remaining 13,611 clean SNPs.

GWAS analysis

A GWAS study was performed using TASSEL 5.2.93, a program that uses evolutionary trait connections and linkage disequilibrium, as explained by Bradbury et al. (2007), to find SNPs related to K and Na concentrations (Bradbury et al., 2007). In this analysis, the relationships between SNP markers and phenotypes were evaluated using mixed linear model [MLM (PCA + K)] approaches (Upadyayula et al., 2006). The association between SNP markers and phenotypic traits was revealed with the help of Manhattan and quantile-quantile (Q-Q) plots generated for both elements and both years. To detect false positive SNPs, the False Discovery Rate (FDR) threshold was determined (Benjamini and Hochberg, 1995), and SNPs that exceeded the FDR threshold and showed significance at the $p < 0.01$ level were considered statistically significant for the accumulation of both elements.

Putative Candidate Gene analysis

To determine the genomic locations and functional importance of SNP markers associated with K and Na concentrations in walnut fruit, the SNP sequences obtained from the GWAS analysis were aligned with the *J. regia* genome with accession number PRJNA350852, thereby identifying candidate genes. Information on these potential genes is listed in Table S2, Table S3 and Table S4.

RESULTS AND DISCUSSION

Determination of potassium (K) and sodium (Na) concentrations in walnut kernels

The K and Na concentrations measured for both years in 154 different walnut genotypes evaluated for K and Na concentrations are shown in Table 1.

Table 1. K and Na accumulations in walnut genotypes over two years: minimum, maximum, and mean values.

Trait	2021			2022		
	Min	Max	Mean	Min	Max	Mean
K (mg/100g)	257.50	822.50	411.80	131.75	850.00	414.57
Na (mg/100g)	2.50	80.00	18.70	2.00	84.50	18.61

The lowest K concentration for both years was determined to belong to genotype 104/114 (genotype number 11, Table S1), while the highest K concentration was found in genotype BAYIR-1 (genotype number 107, Table S1).

While the variation between K concentration values in this study was found to be 6.45-fold, previous studies reported smaller ranges, such as 1.39-fold (Polat et al., 2015), 1.45-fold (Simsek, 2016), and 1.23- and 1.38-fold (Rabadán et al., 2018). These results imply that the range of K concentrations seen in this investigation is greater than those documented in previous research. The wider genetic diversity of the walnut genotypes employed in this study could be the cause of this increased variation (Polat et al., 2015; Simsek, 2016; Rabadán et al., 2018).

These results suggest that genotype 104/114 could be employed in test cross studies to locate genotypes that are rich in K, whereas the BAYIR-1 genotype may be evaluated as a parent in hybridization and biofortification-oriented walnut breeding programs targeting the development of K-rich genotypes.

Genotype 144/84 had the lowest Na concentration in both years, while genotype GIR/14 (Table S1) had the highest Na concentration in both years.

In the present study, the variation between the minimum and maximum Na concentration values was determined to be 42.25-fold, whereas in the aforementioned studies, this variation was 3.23-fold (Muradoglu et al., 2010), 2.83-fold (Yilmaz and Akca, 2017), and 1.93-fold (Ozyigit et al., 2019). The differences in Na concentrations observed in this study display a broader range compared to the findings in previous literature. This may be attributed to the greater genetic diversity of the walnut genotypes used in the current research (Muradoglu et al., 2010; Yilmaz and Akca, 2017; Ozyigit et al., 2019).

Based on the results obtained from this study, the GIR/14 genotype can be utilized in biofortification studies, hybridization programs, and sustainable agriculture practices to create efficient, nutrient-rich, and healthy food sources.

The two-year (2021–2022) data from the K and Na concentration analyses in walnut fruits were used to build a histogram. It was found that the frequency distribution of both elements for the 154 genotypes displayed a normal distribution (Figure 1a, b, c, and d). This indicates that the identified phenotypic traits are likely controlled by numerous genes, may be impacted by environmental factors, are both measurable and continuous, and that most individuals in the population have average values, while individuals with extreme values are fewer. This also indicates that the population is suitable for GWAS studies due to the presence of both extreme and average value individuals.

Fig. 1. Histogram graphs depict the distribution of K and Na contents for two years.

Variance analysis

After analyzing the findings of analysis of variance, it was found that R did not create statistically significant differences in K and Na concentrations (dependent variables). G showed a statistically significant effect at $p \leq 0.01$ level for both dependent variables. However, only K concentration was found to be statistically significantly affected by Y and the Y x G interaction at $p \leq 0.01$.

When the variance analysis results of previous studies were examined, it was found that potassium (K) concentrations showed a significant difference only for crop year (CY) alone, while the genotype (G) × crop year (CY) and genotype interactions in consecutive crop years did not exhibit statistically significant differences at the $p \leq 0.05$ level (Rabadán et al., 2019). However, significant differences were detected at the $p < 0.01$ level for genotype × crop year (G × CY), crop year (CY), and genotype (G) interactions for K concentration (Rabadán et al., 2018). These results indicate that the variability in K content in walnut fruits arises from both genetic factors and environmental influences. In previous studies conducted to determine sodium (Na) concentrations, analysis of variance revealed statistically significant differences among genotypes at the $p < 0.01$ level (Ozcan et al., 2010) and at the $p \leq 0.05$ significance level (Simsek, 2016). In the literature, no other variance analysis studies have been found that evaluate the effects of genotype (G), year (Y), and G × Y interactions on Na concentration in walnut kernels.

These results show that while K accumulation in walnut fruits is regulated by both genetic and environmental variables, Na accumulation is impacted only by genetic factors. Since the walnut fruits were harvested from the same location but grown in two different years, it is considered that soil properties such as pH, total salt (%), and organic matter, as well as climatic conditions such as the number of rainy days and total monthly precipitation, may have changed between the two years. This result provides important insights, particularly for plant breeding, fertilization strategies, and biofortification studies, as it highlights the necessity of focusing not only on genetic composition but also on environmental management strategies.

In the present study, the heritability value for K and Na concentrations was determined to be 0.99. These high values suggest that the influence of genotypic factors on K and Na accumulation in walnut kernels is substantially greater than that of environmental factors. In contrast, previous studies conducted on different plant species have reported lower heritability

values; for instance, Amoah et al. (2023) reported heritability estimates of 0.20 for K and 0.46 for Na concentrations in peanuts (Amoah et al., 2023). A number of variables, such as variations in plant species, genetic variability among genotypes, and environmental circumstances, could be responsible for the disparities between the results of this study and those of other investigations.

The study's conclusions offer significant new information and a useful foundation for genotype selection in walnut breeding initiatives aimed at enhancing nutritional value.

Table 2. Variance analysis results of two-year K and Na accumulations obtained from walnut genotypes.

GWAS analysis

In the GWAS analysis, to eliminate false positive results among the identified SNPs, FDR threshold was applied: K-2021 and K-2022 (FDR = 3.33), Na-2021 and Na-2022 (FDR = 3.50). Manhattan plots were used to show SNPs that exceeded these levels (Fig. 2). Additionally, Q-Q plots were created to illustrate the distribution of P-values demonstrating the relationship between significant SNP markers and K and Na concentrations (Fig. 3). A total of 17 significant SNPs (P <0.01) exceeding the FDR threshold was identified as associated. Out of these SNPs, 16 were related to K accumulation (Table 3) while one SNP was related to Na accumulation (Table 4).

Research conducted for the present study did not find any other studies in the literature that identified SNP markers related to nutrient accumulation in walnut kernels. However, there are research that has found SNP markers related to various traits in walnuts. When these studies are examined, 98 SNP markers associated with seven traits of walnut fruit, 55 significant SNP markers related to nut, kernel, and shell traits, and 259 significant SNP markers identified in different walnut genotypes in response to drought stress have been reported (Arab et al., 2019; Orman et al., 2020; Arab et al., 2022). These findings in the literature demonstrate the importance of the GWAS method in identifying SNP markers associated with specific traits. The identification of SNP markers linked to desirable traits can contribute to plant breeding efforts.

In this study, the R^2 values of the identified SNPs were determined to range from 0.08 to 0.17, while in other studies in the literature, R^2 values were observed to range from 0.08 to 0.19 and from 0.01 to 0.35 (Orman et al., 2020; Arab et al., 2022). These results are consistent with the literature. Based on these findings, markers with high R^2 values can be used in marker-assisted selection (MAS) and breeding programs to select individuals targeting these markers, thereby enabling faster genetic gain.

Future genetic research on walnuts can leverage the SNP markers shown in this work to be related to K and Na concentrations in walnut fruit as genetic resources.

Fig. 3. Q-Q plots of both macronutrients: (a) K-2021, (b) K-2022, (c) Na-2021, (d) Na-2022.

Putative Candidate Gene analysis

The 17 SNP markers associated with K and Na accumulation, identified through the GWAS analysis, were aligned with the *Juglans regia* L. genome and 13 of these SNPs were localized to particular chromosomes in the walnut genome. For 11 SNPs associated with both K-2021 and K-2022 accumulation, 105 candidate genes were identified (Table S1), while 13 candidate genes were detected for the SNP associated only with K-2021 accumulation (Table S2). For the SNP associated with both Na-2021 and Na-2022 accumulation, 18 candidate genes were identified (Table S3).

The serine/threonine-protein kinase PBL9 identified for SNP664 is a member of the PBS1-like kinase family, which has been characterized in *Arabidopsis thaliana* and plays important roles in immune responses and signal transduction (Huang et al., 2021). The gene phospholipid-transporting ATPase 4, located near SNP7893, encodes a protein belonging to the phospholipid-transporting ATPase family and has been identified in *Arabidopsis thaliana*. This gene plays a critical role in maintaining membrane stability and cellular functions by regulating the incorporation of phospholipids into the cell membrane and intercellular transport (Jensen et al., 2017). The candidate genes identified in this study as being associated with K concentration have not previously been reported in the literature to be associated with K concentration in walnut.

These findings may help us better understand the functions of genes associated with K concentration in plant cells. Additionally, investigating genes that do not directly affect K content but may have the potential to influence it indirectly can provide a basis for future research. Considering the importance of the K nutrient for human health and nutrition, the data obtained from the research can offer supportive information for improving the quality of plant-based food sources. Understanding the functions of genes related to nutrient accumulation can also contribute to the cultivation of nutrient-rich plants through genetic engineering approaches, particularly in plant breeding efforts.

CONCLUSION

This study represents the first research in which SNP markers associated with K and Na concentrations were identified using the GWAS method among 154 different walnut genotypes. Genetic variation in K and Na concentrations was detected, and the obtained data hold significant potential for future genetic research on walnuts. Investigating potential genes associated with SNP markers related to nutrient accumulation in the walnut and determining their traits may contribute to plant breeding efforts through genetic engineering approaches. Additionally, enhancing K and Na concentrations in edible plants through biofortification studies may also contribute to the improvement of human nutrition.

ABSTRACT

Botrytis cinerea is a necrotrophic fungal pathogen that is responsible for substantial losses in a wide range of plant species. The detrimental impacts of chemical fungicides on human health and the environment have given increase the interest in alternative control strategies. In this review, the antifungal effects of different propolis extracts on this pathogen were evaluated based on studies that combined *in vitro* and *in vivo* tests. The findings of the *in vitro* experiments demonstrated that propolis extracts have the capacity to inhibit various developmental stages of this pathogenic fungus such as mycelial growth, sporulation, and conidial germination. However, the effectiveness of this inhibition was changed with concentration of the extract and the method of preparation. In this context, it has been demonstrated that extracts prepared based on the use of ethanol at high concentration and sonication method have a stronger antifungal effect. *In vivo* test demonstrated that the treatment of propolis to the fruits of plants including strawberries, grapes, blueberries and tomatoes led to a reduction in both the disease incidence and infection area by the pathogen, although this effect exhibited the variability with plant species, the application method and dosage. Consequently, while propolis reveals considerable antifungal potential against *B. cinerea*, additional researches are required on the standardization of extracts, the optimization of doses, the determination of application timing and *in vivo* tests on different plant species to increase its applicability in agricultural practices.

Keywords: *Botrytis cinerea*, propolis extract, antifungal effect, *in vitro* and *in vivo* tests

INTRODUCTION

Propolis is a complex natural compound that is formed by honeybees (*Apis mellifera*) by combining the natural substances they collect from plant buds, resins and leaf sap with their own enzymatic secretions. The word 'propolis' is derived from the Greek word's 'pro', meaning 'front or entrance', and 'polis', meaning 'city-colony', which indicates that it was used in its hive defense. Propolis is characterised by its flexibility, softness and stickiness at high temperatures, while it becomes hard and brittle when cooled. Due to these properties, it is used by honeybees to close cracks and holes and strengthen the structure of beeswax combs in order to keep the temperature and humidity inside the hive constant throughout the year (Sforcin, 2007).

From antiquity to the present, propolis has been utilized as an antiseptic and disinfectant for oral and skin illnesses in ancient Greece, primarily in traditional medicine, and by the Egyptians during mummification procedures (Havsteen, 1983; Burdock, 1998). This particular bee product, which has a wide range of uses, has been shown to contain over 300 chemical compounds (Huang et al., 2014). The chemical composition of raw propolis typically consists of 50% plant resins, 30% waxes, 10% essential and aromatic oils, 5% pollen, and 5% other organic substances (Bankova, 2005). However, the main chemical groups in propolis resin are

phenolic acids and their esters, terpenes, flavonoids, aromatic aldehydes and alcohols, stilbenes, fatty acids, and β -steroids (Watanabe et al., 2011; Ahangari et al., 2018; Przybylek and Karpinski, 2019). Despite the chemical diversity of propolis, comprehensive research has revealed the existence of at least six main types (Ghallab et al., 2024).

Figure 1. The main types of propolis (Ghallab et al., 2024).

Following the demonstration of the anticancer, antioxidant, anti-inflammatory, antibiotic, antifungal and antihepatotoxic properties of propolis by Ghisalberti (1979), there has been an increase in the number of modern controlled experimental studies on the chemical structure and biological activities of this substance. *Botrytis cinerea*, the causal agent of gray mold disease in several plant species and a major cause of yield losses both in the field and post-harvest (Williamson et al., 2007; Dean et al., 2012), took a place among the fungal pathogens against which propolis was tested. The ability of this fungal pathogen for development of resistance exhibited by this fungal pathogen to fungicides has rendered the use of alternative compounds to control it, such as propolis, increasingly significant.

Some of the studies have been conducted *in vitro* to investigate the impact of propolis on *B. cinerea* (Sapieha-Waszkiewicz et al., 2011; Curifuta et al., 2012; Yang et al., 2016; Ezazi and Davari, 2018; Wuaden et al., 2018; Ouahab et al. 2023; Erdoğan and Güzel, 2025). However, the results of *in vivo* tests involving plant parts are more significant in determining the practical applicability of this compound. In this review, the effect of propolis against this pathogen was discussed in the light of the findings obtained from both *in vitro* and *in vivo* stages, with emphasis placed on the highest effects observed in the studies. Within this context, *in vitro* studies are incorporated into the text according to their chronological sequence, while *in vivo* studies are presented in tabular form. Articles belonging to the research conducted until today were obtained by using many databases in Tekirdağ Namık Kemal University library.

STUDIES ON THE EFFECTS OF DIFFERENT PROPOLIS EXTRACTS AND APPLICATIONS ON *Botrytis cinerea*

In the study conducted by Darweesh (2010), samples of propolis collected from Baghdad, Iraq, were prepared using 96% ethyl alcohol and subsequently added to Potato Dextrose Agar (PDA) medium at doses of 1.25, 2.5, and 5 mg/ml. The researcher then has determined the pathogen's colony diameter and mycelial growth rate seven days after placing a mycelial disk of the pathogen in the center of each petri dish. In the study, the same concentrations were also added to Potato Dextrose Broth (PDB) medium and mycelial dry weights were measured after 14 days of incubation at 25°C. *In vitro* tests of the study revealed that a concentration of 5

mg/mL of propolis extract led to a 100% reduction in both the colony growth and the mycelial dry weight in PDA and PDB media. This dose was applied to eggplant leaves and cucumber fruit, and its efficacy against the pathogen *in vivo* was tested (Table 1). In addition, the chemical composition of propolis was analysed using infrared spectroscopy, and the presence of flavonoids was determined.

In a study conducted by Moura et al. (2016), extracts of two different types of propolis (green and brown) prepared with ethanol were added to PDA medium, which were present in 9 cm Petri dishes at doses of 0.5% and 2.5%, and the mycelial disk of the pathogen was placed on it. Petri dishes were incubated at 25°C and the colony diameter of the pathogen was measured at 48, 72 and 96 hours after inoculation. Following a thorough evaluation of the study's findings, it was determined that both 0.5% and 2.5% doses of green propolis exhibited a higher antifungal effect against the pathogen in comparison to brown propolis. Findings from the study indicated that a 2.5% dose of green propolis led to a 33.67%, 43.90%, and 43.23% inhibition in colony development at 48, 72, and 96 hours after inoculation, respectively; these values were higher in comparison to the inhibition rates of brown propolis at same dose. In the study, both propolis were tested using strawberry fruit *in vivo* at both doses (Table 1).

Table 1. Some studies conducted under *in vivo* conditions against *Botrytis cinerea*

Treatment	Scope	Result / Effectiveness	Author
Application of propolis ethanol extract (5 mg/ml) to eggplant leaves and cucumber fruits at different times before and after inoculation [dropping of conidia suspension (1×10^6 conidia/mL) into wounds opened on leaves and fruits] of the pathogen	Determination of the effect of application time (both 24, 48 hours before and after inoculation) on the growth of <i>B. cinerea</i>	The treatments made 24 and 48 hours before inoculation significantly slowed down disease development.	Darweesh (2010)
Spraying of a conidia suspension of the pathogen at a concentration of 1×10^5 conidia/mL after one minute immersion of strawberry fruits in solutions of green and brown propolis at 0.5% and 2.5% doses	Control of pathogen development in the cultivar (cv) Camarosa with different propolis doses	No difference was observed between the two propolis extracts in terms reducing disease incidence, with an overall inhibition rate of 12.5% being determined. The 0.5% dose of green propolis inhibited the disease severity at the highest rate (23.08%).	Moura et al. (2016)
After covering cherry tomatoes with pullulan film containing propolis ethanol extract (5% and 10%), the inoculation of the pathogen conidia suspension (10 µl) to the wound	Determining the protection of the application by measuring the pathogen population on tomatoes	There was no reduction in the population of coated pathogens after 14 or 21 days.	Pobiega et al. (2020)
Inoculation of pathogen (10 µL) into wounds opened with a pipette tip after immersing grapes	Evaluation of the effect of different propolis types	In the study, after 15 days, Portuguese propolis (~16.3%) was	Diallo (2021)

berries in propolis solutions (15 g/L) for 2 minutes (min)	(Portuguese, Brazilian red) on the decay area caused by <i>B. cinerea</i>	found to be effective in red grapes and Brazilian red propolis in white grapes (~21.5%) were found to be effective, even if at low rates.

Immersion of strawberry fruits in propolis extract (20-, 40- and 60-mL/L) for 30 da, keeping at 25°C for 24 hours and inoculation of conidia suspension of the pathogen	Monitoring the rate of disease incidence at different times (24, 48, 72 hours), determining the PAL (phenylalanine ammonia-lyase) enzyme activity and total phenolic substance amount, which play a role in resistance	No significant decrease in disease incidence was observed at any time point at any of the three doses, and an increase was observed at higher doses. Although the total phenol content of the fruit decreased, PAL enzyme activity increased by only 7.61% after 72 hours.	Stefanski et al. (2024)
Inoculation of 5µl of conidia suspension of the pathogen into the fruits using a sterile needle; for volatile compounds, the placement of the inoculated fruits on sterile papers with 100 µl of extract; for non-volatile compounds, treating the extracts (5 µl) to the wounds on the fruit arranged on the grid one hour after inoculation.	Evaluation of the effect of volatile and non-volatile compounds in extracts on disease incidence	PFvg1 extract exhibited strong antifungal activity (~60-80%) for both compounds. PFvg2 followed it.	Sadallah et al. (2025)

Pobiega et al. (2020) determined the minimum inhibitory concentration (MIC) value for *B. cinerea* as 2 mg/mL and the minimum fungicidal concentration (MFC) value as 8 mg/mL as a result of serial dilution tests prepared with propolis ethanol extract (EEP). In the conducted study, additionally, pullulan films containing 5% and 10% EEP were prepared, and 6 mm diameter discs were cut from these films and placed on Sabouraud agar media spread with conidia suspension. Cellulose discs coated with EEP at the same concentration have been used as the control group. The experimental findings revealed that no inhibition zones were observed in any of the treatment groups. The *in vivo* tests of the study were carried out on cherry tomato fruits (Table 1).

In a study performed by Diallo (2021), the antifungal effects of three distinct propolis ethanol extracts (Portuguese propolis, Brazilian green propolis, and Brazilian red propolis) on *B. cinerea* G3 isolate were investigated. For the present study, the extracts were prepared at doses of 0.5 g/L, 1.5 g/L, 5 g/L, and 15 g/L, and were compared with a commercial fungicide and a fungicide containing the active ingredient tebuconazole. Both agar disk diffusion and well diffusion methods were used in the *in vitro* experiments. In the disk diffusion assay, square dishes containing 50 mL of PDA were prepared, and a conidial suspension with a density of 1×10^6 conidia/mL was spread evenly onto the medium using a sterile swab. Subsequently, a total of nine filter paper disks were placed on the surfaces, and 100 µL of the extract was

dropped onto each disk. In the well diffusion method, the same volume (100 μ L) of solution was applied to each well (nine wells punched with the back of a sterile Pasteur pipette on the agar) and the experiments were conducted separately for different extracts. The dishes were then subjected to an incubation process at a temperature of 25°C for a period of five days. Following the conduction of the experiments, it was reported that none of the propolis species examined in both methods demonstrated antifungal efficacy at the applied doses. *In vivo* tests were conducted utilising extracts at a concentration of 15 g/L and grape berries. (Tablo 1).

Stefanski et al. (2024) examined the effects of an ethanol extract of brown propolis on mycelial development, sporulation and conidia germination of *B. cinerea* under *in vitro* and *in vivo* conditions. In the *in vitro* experiments, propolis extract was added to PDA medium at doses of 20, 40, and 60 mL/L. Petri dishes with a 5 mm diameter *B. cinerea* mycelium disk placed in the center were then incubated at 25°C for 6 days. Colony growth was measured daily, and conidia counts were performed at the conclusion of the sixth day. In the study, it was indicated that mycelial growth rates were significantly reduced and that sporulation was absent at doses of 40 and 60 mL/L. *In vivo* studies on strawberry fruits demonstrated that the three doses were ineffective in reducing disease incidence (Table 1.).

Sadallah et al. (2025) evaluated the antifungal activity of propolis samples [PFvg1 (Friuli Venezia Giulia), PFvg2 (Friuli Venezia Giulia), PU3 (Umbria), PV4 (Veneto), PT5 (Tuscany)] obtained from different geographical coordinates of various Italian regions against *B. cinerea* isolate obtained from grape berries, both *in vitro* and *in vivo* (Table 1). In the study, samples of propolis were prepared by extraction with a range of solutions of ethanol (30%, 60% and 90% v/v). *In vitro* tests were carried out in which the conidia suspension of the pathogen (1×10^5 conidia/mL) was spread on PDA medium, 80 μ L of extract was applied to the wells (5 mm in diameter) on the medium, and the inhibition zones were measured after 72 hours. The findings of this test demonstrated that the widest inhibition zone was observed in the use of PU3 propolis extract, which was prepared with 90% ethanol. The researchers also had ascertained the EC₅₀ value for volatile and non-volatile compounds of each extract based on conidia germination using increasing doses (0, 3.2, 6.5, 12.5, 25, 50, 100, 150 and 200 ppm) of propolis extracts obtained by sonication with 90% ethanol for 24 hours. For tests involving volatile compounds, filter papers were placed on conidia suspensions spread on PDA medium, and the relevant dose of propolis extract was applied to each. For non-volatile metabolites, volatile compounds (100 μ l) were added one hour after the pathogen spread onto the medium. Petri dishes were subjected to an incubation process at a temperature of 20°C for a duration of 48 hours. The outcomes of these experimental tests had indicated that PFvg2 (EC₅₀: 1.36 mg/ml) was identified as the most effective extract in regard to volatile compounds, while PU3 (EC₅₀: 2.24 mg/ml) was determined to be the most effective extract in relation to non-volatile compounds. In *in vivo* tests, the EC₅₀ value of each extract was used as the dose.

CONCLUSION

The *in vivo* studies referenced in this review demonstrate the significant antifungal potential of propolis extracts against *B. cinerea*. However, the extent of this efficacy is dependent on numerous factors, including the chemical composition of the propolis, the extraction method, the type of solvent utilised, the dose, the timing of application and the target plant tissue. The extant literature reveals that research studies have examined the efficacy of propolis extracts on the plants at post-harvest stage, with promising results obtained. The efficacy of propolis under *in vivo* conditions has been proven by significant reductions in disease incidence and lesion development, particularly in high-value crops with perishable properties, including strawberries, grapes, blueberries, cucumbers and tomatoes. The fact that propolis is not only used in the context of agricultural products but also in human health, with

its antimicrobial, antioxidant and anti-inflammatory properties, renders it a versatile and safe product. In this context, the utilisation of propolis, a substance that has been demonstrated to be effective in both human health and in the inhibition of plant pathogens, particularly in the control of fungal diseases in the post-harvest period in fruits, will not only result in a reduction of product loss but also contribute to food safety by eliminating the risk of chemical residues. In conclusion, propolis extracts, with their naturalness, environmentally friendly composition, and multiple biological activities, have the potential to become a significant component of sustainable agricultural practices in the future to control postharvest diseases. However, further studies on various fruits and vegetables are needed to integrate this potential into agricultural practice.

ABSTRACT

Fusarium culmorum is a destructive soil-borne fungal pathogen responsible for root and crown rot in wheat (*Triticum aestivum*), leading to significant yield losses globally in the areas where wheat was cultivated. Biological control agents such as *Trichoderma harzianum* have shown promising antagonistic effects against *F. culmorum* under optimal conditions; however, understanding their performance under abiotic stress is also crucial for practical applications. This study aimed to evaluate the antagonistic activity of *T. harzianum* against a highly virulent *F. culmorum* isolate under increasing salinity. In the first stage, Potato Dextrose Agar (PDA) medium was amended with 50, 100, and 150 mM NaCl, and dual culture assays were conducted. In these tests, *T. harzianum* inhibited the mycelial growth of *F. culmorum* by 40.62%, 40.00%, and 38.75% at 50 mM, 100 mM and 150 mM salt concentrations, respectively, compared to 65% inhibition under non-saline control. In the second stage, wheat seeds co-inoculated with both the pathogen and antagonist were placed on PDA medium containing 50 and 100 mM NaCl. Under these conditions, *T. harzianum* suppressed *F. culmorum* colony development around the seeds by 70.64% at 50 mM and 45.16 % at 100 mM NaCl. These results indicate that *T. harzianum* retains significant biocontrol potential under moderate salt stress. It was demonstrated that high salt levels reduced antagonistic activity in dual culture tests, while protective activity increased around the seed at salt concentrations that did not inhibit plant growth. The study presents promising results regarding the potential use of *T. harzianum* as a biocontrol agent against *F. culmorum* in wheat cultivation in saline regions.

Keywords: *Trichoderma harzianum*, salt stress, *Fusarium culmorum*, antagonistic effect, seed colonization

INTRODUCTION

Approximately 7% of the world's land, including 20% of agricultural land, is affected by salinity problems. Consequently, it is estimated that all agricultural lands worldwide will face challenges related to salinity by the year 2050 (Shahid et al., 2018; Singh et al., 2019; Otlewska et al., 2020). The increase in salt concentrations is capable of inducing alterations in both plant life and microbial ecosystems. Recent studies have demonstrated that the application of varying salt levels to cultivated plants or the cultivation of the plants under salinity stress can enhance the flavour and aroma of the crop. However, it has been reported that such conditions can facilitate the growth of fungal pathogens (Dikilitaş ve Karakaş, 2014). Plants and microorganisms both exhibit distinct responses to salt stress. It has been demonstrated that plants exposed to salt stress become more susceptible to fungal pathogens such as *Alternaria solani*, *Fusarium oxysporum*, *Macrophomina phaseolina*, *Phytophthora* spp. and *Verticillium dahliae*, due to their reduced resistance (Swiecki and MacDonald 1991; Nachmias et al. 1993; Triky-Dotan et al. 2005; Goudarzi et al. 2011).

Wheat (*Triticum aestivum* L.) is considered to be one of the most significant crops cultivated in arid and semiarid regions (Shiferaw et al., 2013). Limiting factors for wheat production include nutrient deficiencies in soil, drought, salinity stress and the presence of the pathogens causing the diseases. *Fusarium culmorum*, a fungal pathogen transmitted through seeds and soil, has been responsible for significant yield losses by causing pre- and post-emergence damping-off in plants (Pasquali et al., 2016). In the case of the pathogen being present in the soil, the recommendation has been for seed treatment with various fungicides. However, due to the various adverse effects of chemicals on the environment and human health, seed treatments with the biological control agent *Trichoderma harzianum* have also been shown to be sufficiently successful against this pathogen (Erdurmuş and Katırcıoğlu, 2008; Kthiri et al., 2020; Özdamar and Özer, 2022; Vitti et al., 2022). Upon the colonisation of plant roots by this antagonist fungus, the increase in the activities of various enzymes, including peroxidase, chitinase, β -1,3-glucanase, and lipoxygenase-pathway hydroperoxide lyase is occurred. This process is of critical importance for the increases in plant growth, the accumulation of compounds that are involved in resistance, and improved nutrient uptake, as well as the development of tolerance to salt stress in plants (Shoresh et al., 2010; Contreras-Cornejo et al., 2016). However, it is known that the development of *T. harzianum* is also affected by different factors (salinity, temperature, heavy metal) (Mohammed ve Haggag, 2006; Poosapati et al., 2014; Rawat et al., 2013; Contreras-Cornejo et al., 2016; Mbarki et al., 2017; Bozdeveci et al., 2019; Abu-Shahab et al., 2022; Rawat et al., 2022; Abdelrhim et al., 2024).

In previous years, studies have been conducted on the effects of *T. harzianum* on various fungal pathogens causing root and crown rot in different plant species under in vitro and in vivo conditions at different salinity levels. These include *Fusarium oxysporum* f. sp. *lycopersici* in tomato (Mohammed and Haggag, 2006), *F. oxysporum* f. sp. *ciceri* in chickpea (Rawat et al., 2013), *Sclerotinia sclerotiorum* in bean (Abdelrhim et al., 2024) and *F. udum* in pigeon pea (Mishra et al., 2024). In the case of wheat, only *F. pseudograminearum* has been investigated in this context (Boamah et al., 2021). To date, no study has examined the effects of *Trichoderma harzianum* application on wheat under combined salinity stress and *F. culmorum* infection, which is prevalent in our country. This work aimed to test the antagonistic activity of *T. harzianum* against *F. culmorum* and its impact on seed colonization by the pathogen, under different levels of salinity stress.

MATERIAL AND METHOD

The pathogenic fungus isolate used in the experiments was *F. culmorum* (S-14), which was isolated from wheat exhibiting symptoms of root and crown rot in the Thrace Region and is known to be pathogenic. The wheat cultivar Flamura 85, which is susceptible to this pathogen, was employed in the study (Köycü and Özer, 2019). The antagonist fungus was *T. harzianum* (TRIC8, Accession number: MH351669), which was isolated from onion-grown soils in Tekirdağ province and exhibited antagonistic properties (Özer et al., 2009). The pathogenic isolate was grown on Potato Sucrose Agar (PSA), while the antagonist fungus was cultured on Potato Dextrose Agar (PDA-Merck) in an incubator (Binder) maintained at 23°C.

In *in vitro* experiments, 0, 50, 100 and 150 mM NaCl concentrations were added to the PDA medium for salt tolerance and then poured into 8.5 cm diameter petri dishes after autoclaving at 121 °C for 20 min. Following the solidification of the medium, an agar disc (5 mm diameter) from the pathogen culture (grown in PSA medium) and the culture of the antagonist (grown in PDA medium) were positioned in opposite directions, at a distance of 1 cm from the outer edges of the petri dish (dual culture). Furthermore, in the context of pathogen control (PK), an agar disc containing solely the pathogen was positioned in the center of the petri dish. All petri dishes were incubated in a refrigerated incubator (Binder) at 23°C for 7 days. Subsequent to the incubation period, the colony radius of the pathogen was measured in

each treatment, and the inhibition rate of the pathogen by *T. harzianum* was calculated using the following formula: [Inhibition rate (%) = (colony radius of the pathogen in pathogen control (PC) dishes– colony radius of the pathogen in dual cultures containing different salt concentrations) / PC × 100]. The experiments were conducted in four replicates, with a petri dish in each replicate.

In order to determine the effect of *T. harzianum* on *F. culmorum* colony development around wheat seeds under salt stress, concentrations of 50 mM and 100 mM were selected, corresponding to low and moderate salt levels, respectively. PDA media containing NaCl at these concentrations were poured into 8.5 cm diameter petri dishes. The seeds were immersed in a 2% sodium hypochlorite (NaOCl) solution for a period of seven minutes, following which they were rinsed three times with sterile distilled water. Thereafter, they were dried on sterile filter paper for a period of 30 minutes. Surface-sterilized seeds were then placed in a suspension mixture containing conidia of *F. culmorum* (1×10^6 conidia/ml) and *T. harzianum* (1×10^7 conidia/ml), which had been supplemented with 0.1% Tween 20, and shaken at 25 °C for one hour. For the pathogen seed control (PSC), only the conidial suspension of the pathogen was used. The treated seeds were then placed in Petri dishes (10 seeds per dish). The experiments were conducted with five replicates, each consisting of one Petri dish. Subsequent to a period of incubation at a temperature of 23 °C for a duration of seven days, the diameter of the colony of *F. culmorum* developing around the seeds was measured. The inhibition rate by *T. harzianum* was calculated using the following formula: [Inhibition rate (%) = (PSC – colony diameter of the pathogen around seeds treated with pathogen + *T. harzianum* under different salt concentrations) / PSC × 100], where PSC refers to the colony diameter of the pathogen around seeds inoculated only with the pathogen.

The homogeneity of variances and the normality of distribution were first assessed using Levene's test and the Shapiro–Wilk test, respectively, in SPSS version 23 (IBM SPSS Statistics for Windows, IBM Corp., Armonk, NY, USA). All experiments met the assumptions of the ANOVA test. The Tukey HSD test was performed using JMP Pro version 17 for Windows (SAS Institute Inc., Cary, NC, USA) to compare treatment means at the 0.05 probability level.

RESULTS AND DISCUSSION

In the present study, the colony radius of *F. culmorum* was determined to be 4.00 cm in pathogen control (PK). In the salt-free medium (0 mM, P+T), its colony radius decreased to 1.40 cm with the presence of *T. harzianum* (dual culture), with the lowest value observed in this treatment (Table 1, Figure 1 A). In this medium, *T. harzianum* demonstrated an inhibition rate of 65% against the growth of the pathogen. However, the inhibition rate of the pathogen by the antagonist fungus at salt concentrations ranging from 50 to 150mM (Figure 1 B-D) varied between 40.62% and 38.75%, and the differences between these levels were determined to be statistically non-significant.

Two doses, which exhibited a similar inhibitory effect on mycelial colony development of *F. culmorum*, were added to the PDA medium. Subsequently, wheat seeds coated with the pathogen and *T. harzianum* were placed on the medium, and the colony development of the pathogen around the seeds was measured. In the conducted tests, the colony diameter of *F. culmorum* was measured at 2.55 cm in the pathogen seed control (PSC) group. The colony diameter of the pathogen decreased to 0.26 cm in the presence of *T. harzianum* in salt-free medium (0 mM, P+T), with the highest recorded inhibition rate of the pathogen by the antagonist (89.92%) being determined in this medium (Table 2, Figure 2A). The medium supplemented with 50 mM NaCl was found to be the second rank in terms of low colony diameter around the seed (Figure 2B). In this medium, *T. harzianum* inhibited the colony

growth of the pathogen by 70.64%. At a salt concentration of 100 mM (Figure 2C), the inhibition rate decreased to 45.16%. The differences between 50 and 100mM salt concentrations with regard to colony diameter and inhibition rate were detected to be statistically significant.

Table 1. Effect of *Trichoderma harzianum* on mycelial colony growth of *Fusarium culmorum* at different salt concentrations.

Salinity (mM)	Mycelial colony radius (cm)*	Inhibition of mycelial colony growth (%)*
PC	4.00±0.00 a	-
0 (P+T)	1.40±0.07 c	65.00±1.77 a
50 (P+T)	2.37±0.05 b	40.62±1.20 b

It has been established for a long time that there are variations in salt tolerance among different *Fusarium* spp. (Mandeel, 2006; Shoaib et al., 2018; Maharshi et al., 2021; Tiwari et al., 2024). This has resulted in a varying range of consequences regarding the impact of *T. harzianum* on *Fusarium* spp. at differing levels of salinity. In this context, the highest inhibition of colony growth of *F. oxysporum* f. sp. *lycopersici* by *T. harzianum* (40.4%) was at 69 mM salinity concentration (Mohammed and Haggag, 2006); while these values were determined as 70 mM for *F. oxysporum* f. sp. *ciceri* (93.66%) (Rawat et al., 2013), 150 mM for *F. pseudograminearum* (46.42%) (Boomah et al., 2021), and 684.46 mM for *F. udum* (60%) (Mishra et al., 2024). As stated in the study by Rodriguez et al. (2008), some isolates of *F. culmorum* were capable of growth at concentrations of up to 500 mM NaCl. This finding suggests that some isolates of the species may have developed tolerance to high salt concentrations. The inhibitory effect of *T. harzianum* on *F. culmorum* was found to be limited, with levels of 40.62%, 40% and 38.75% observed at 50, 100 and 150 mM NaCl concentrations, respectively, in the present study. This may be attributable to the salt tolerance exhibited by the *F. culmorum* isolate of the current study.

In the present study, *T. harzianum* and *F. culmorum* were applied to seeds, and the level of *T. harzianum*'s ability to prevent the development of the pathogen around the seed was determined. The experiment revealed that a higher inhibition rate (70.64%) as compared to the 40.62% inhibition rate obtained in dual culture at 50 mM salinity, was determined at the same concentration in the seed medium. This finding is consistent with studies conducted on plant-salinity-*T. harzianum*-*Fusarium* spp. interactions (Mohammed ve Haggag, 2006; Boomah et al., 2021; Mishra et al., 2024). In a study conducted by Mohammed and Haggag (2006), it was observed that *T. harzianum* was capable of inhibiting *F. oxysporum* f. sp. *lycopersici* infection in tomato by 56.48% in a 4 mM NaCl concentration. In a similar manner, *F. pseudograminearum* infection in wheat was reduced by 52.78% in 50 mM NaCl concentration (Boomah et al., 2021), and *F. udum* infection in pigeon pea was significantly inhibited at 48 mM NaCl level (Mishra et al., 2024). It has been documented that in the context of pathogen-antagonist interactions occurring in plant parts, fungi compete for nutrients secreted from the plant, with *T. harzianum* prevailing in this competition (Tyśkiewicz et al., 2022). *T. harzianum* has the capacity to saprophytically colonise the seed surface. This growth is hypothesised to be the result of several mechanisms, including competition and mycoparasitism (Brozova, 2004, Güçlü and Özer 2022). It is thought that the *T. harzianum* isolate used in this study provides an advantage over *F. culmorum* in salty conditions in relation to the ability to use the nutrients released during seed germination, thus increasing its capacity to suppress this pathogen.

CONCLUSIONS

The present study demonstrated that the *T. harzianum* isolate used in this work significantly inhibited the mycelial growth of *F. culmorum*, particularly around seeds, under different salinity conditions. The high inhibition rates observed at low and moderate salinity levels indicate that this isolate can remain effective under salt stress. These findings suggest that the applied *T. harzianum* isolate may be a promising biocontrol agent against *F. culmorum*, the causal agent of crown and root rot in wheat, in saline environments. However, further investigations under field conditions and on different crops are required to substantiate these results.

ABSTRACT

In this study, we report the synthesis and full characterization of a novel o-tolidine-based fluorescent monomer, 4,4''-bis(2'-fluorenylideneimino)-3,3''-dimethylbiphenyl, obtained via Schiff base condensation between o-tolidine and two equivalents of fluorene-2-carbaldehyde. Structural confirmation was achieved through IR and NMR spectroscopies, while optical properties were assessed using UV–Vis and fluorescence spectroscopy, revealing strong absorption in the ultraviolet region and a band gap of 2.58 eV. Electrochemical analysis via cyclic voltammetry showed the monomer has a HOMO energy level of –6.04 eV and a LUMO level of –3.46 eV. Subsequently, the monomer was successfully electropolymerized onto a platinum electrode through cyclic voltammetry, forming a thin, adherent, and electroactive film. The resulting polymeric material displayed enhanced electronic delocalization due to increased π -conjugation. This was confirmed by a significant narrowing of the band gap to 1.80 eV, as well as an upward shift in the HOMO level to –5.41 eV, and in the LUMO level to –3.61 eV.

These results demonstrate that polymerization leads to a reduction in band gap and improved charge transport, consistent with the extension of the conjugated system in the polymer backbone. Considering the electronic properties of the polymer, it is well-suited as a donor material in organic photovoltaic (OPV) applications. Its HOMO/LUMO alignment is favorable for pairing with fullerene-based acceptors such as [6,6]-Phenyl-C₆₁-butyric acid methyl ester (PCBM), which possesses a LUMO level of approximately –4.0 eV. This offset ensures efficient exciton dissociation and electron transfer, satisfying the energy level requirements for high-performance bilayer or bulk heterojunction solar cells. These findings underscore the potential of the synthesized electropolymer as a promising donor material for future development of solution-processed or electrochemically deposited OPV devices.

Keywords: Organic photovoltaic cells; Cyclic voltammetry; HOMO; LUMO; Gap.

INTRODUCTION

Electroactive polymers have gained increasing interest due to their reversible redox properties, their ability to store charge, and their potential applications in sensors, electrochromic devices, supercapacitors, and fuel cells [1–4]. Among these, semiconducting polymers synthesized via electropolymerization on conductive substrates offer the advantage of in situ controlled film growth, enabling precise tuning of thickness and morphology [5,6]. The monomer FLTFL, investigated in this study, exhibits structural features favorable for the formation of a stable, reversible, and electroactive polymer film. To evaluate its electrochemical behavior, a multi-technique approach was adopted: cyclic voltammetry (CV) to monitor oxidation, reduction, and polymerization processes [7], and electrochemical impedance spectroscopy (EIS) to characterize the deposited film [8].

RESULTS AND DISCUSSION

2.1. Oxidation and Reduction Behavior of FLTFL Monomer

Cyclic voltammetry of the FLTFL monomer shows a distinct oxidation wave between +0.6 and +0.9 V, indicating the formation of radical cations that initiate polymerization. A smaller reduction wave appears on the reverse scan, near +0.8V, suggesting a partially reversible redox process, characteristic of an EC mechanism (electrochemical step followed by a chemical reaction). This confirms the monomer's ability to form an electroactive polymer film.

Figure 1. Cyclic voltammogram of the FLTFL monomer.

2.2. Electronic properties of monomer

The tolidine-based azomethines, characterized by their symmetrical structure and dual-point functionalization, provide greater versatility in bandgap modulation and a finer degree of control over frontier orbital energy levels. FLTFL is particularly well-suited for applications such as in bulk heterojunction (BHJ) organic solar cells (Figure 2).

Successive CV scans reveal a progressive increase in oxidation current, indicating continuous growth of the polymer film on the electrode surface. The increasing peak currents and evolving wave shapes are typical of electroactive polymer deposition. The growing current response confirms that the film is adhering and expanding effectively, consistent with a conductive polymer film being formed during each cycle.

Figure 2. Work functions of electrodes and HOMO and LUMO energy levels of the materials for ITO/poly-3-hexylthiophene/FLTFL/Al device.

2.3. Electropolymerization of FLTFL

Figure 3. Successive CV scans during FLTFL electropolymerization. The increasing peak current shows continuous growth of the polymer film.

2.4. Electroactivity of Poly(FLTFL)

The redox behavior of the polymer shows a clear oxidation peak and a less intense reduction peak, indicative of partial reversibility. This suggests that the polymer undergoes doping (oxidation) and dedoping (reduction) transitions within a defined potential window, behaving like a typical p-type conducting polymer. The polymer is thus capable of reversible charge exchange, essential for practical electrochemical applications.

Figure 4. Redox behavior of poly(FLTFL): clear oxidation peak and asymmetric reduction wave, typical of p-dopable materials.

The optoelectronic properties of the polymer derived from the o-tolidine-based fluorinated monomer highlight its strong potential for application in organic photovoltaic (OPV) devices. The significant reduction in band gap after polymerization (from 2.58 eV to 1.80 eV) reflects an enhanced π -electron delocalization, resulting from the extension of the conjugated backbone. This favors light absorption across a broader portion of the solar spectrum. Moreover, the HOMO/LUMO energy levels of the polymer (-5.41 eV / -3.61 eV) exhibit favorable alignment with fullerene-based acceptors, such as [6,6]-Phenyl-C₆₁-butyric acid methyl ester (PCBM), which has a LUMO level around -4.0 eV. This energy offset ensures efficient exciton dissociation and electron transfer, two key factors for optimal solar energy conversion.

Owing to its excellent electrochemical stability, ability to form thin and adherent films via electropolymerization, and intermediate semiconducting properties, the polymer presents itself as a promising donor material for application in bulk heterojunction organic photovoltaic (OPV) cells, high-performance bilayer device architectures, and fully electrodeposited active layers, which allow for simplified and potentially more cost-effective fabrication compared to conventional solution-processed devices. These findings also suggest that the polymer may be suitable for integration into other organic electronic systems, including electrochemical sensors, organic light-emitting diodes (OLEDs), and electrochromic devices, where controlled conductivity and tunable optical responses are essential.

2.5. Electrochemical Impedance Spectroscopy (EIS)

EIS analysis of the polymer-coated electrode displays a semicircular Nyquist plot, indicative of charge transfer control. The data was fitted using a Randles equivalent circuit, yielding the following parameters:

- $R_s = 1794.29 \, \Omega \cdot \text{cm}^2$ (solution resistance)
- $R_{ct} = 11,178.79 \, \Omega \cdot \text{cm}^2$ (charge transfer resistance)
- $C_{dl} = 2.18 \, \mu\text{F} \cdot \text{cm}^{-2}$ (double-layer capacitance)

The high R_{ct} reflects the film's low conductivity in its neutral state, while the modest C_{dl} suggests a compact, low-porosity interface. This behavior is typical of weakly doped semiconducting polymers.

Figure 5. Nyquist and Bode plots (EIS) of poly(FLTFL) on platinum, showing a semicircular arc characteristic of charge transfer control. Fit with Randles model.

Compared to doped polymers like polypyrrole (PPy) or poly(3,4-ethylenedioxythiophene) (PEDOT), which typically show R_{ct} values of 100–500 $\Omega \cdot \text{cm}^2$ and C_{dl} values around 4–8 $\mu\text{F} \cdot \text{cm}^{-2}$ [9–11], poly(FLTFL) shows significantly higher resistance and lower capacitance. These results suggest an intermediate behavior: more active than insulating polymers like polythiophene (PTh) [12], yet less conductive than PEDOT. This positions poly(FLTFL) as a promising candidate for applications that require moderate redox activity and good film stability, such as sensors or electrochromic devices [13,14].

CONCLUSION

The results demonstrate that FLTFL can be successfully electropolymerized onto a platinum electrode to form a stable and electroactive polymer film. The film exhibits typical p-type redox behavior with significant oxidative activity and minimal reduction response. EIS data confirm a compact and weakly conductive interface in the neutral state, but one that is potentially redox-active under applied potential. These characteristics suggest that poly(FLTFL) is suitable for devices relying on oxidative switching, such as unidirectional redox sensors or asymmetric charge storage systems. Future work could explore doping strategies, co-monomer integration, or alternative potential windows to optimize its performance.

ABSTRACT

The river Shkumbini is one of the most erosive rivers in Albania and it lies in the central part of the country. Our fieldworks were done in the riparian areas from Peqin to Elbasan area, during the last two years. Among vascular plant collected, we identified up to 254 taxa, consisting into 55 plant families, each of them represented by different levels of species richness. The most represented families were: Poaceae (12%), Fabaceae (11%), Lamiaceae (7%), and Brassicaceae (5%), according to their proportional occurrence. The predominant biological forms observed were hemicryptophytes, therophytes, and phanerophytes. Referring to the data collected, the riparian flora of the studied area is predominated by *Populus alba* L., *Salix alba* L., *Salix eleagnos* Scop., *Alnus glutinosa* (L.) Gaertn., *Typha minima* Hoppe, *Carex* sp., etc. The anthropogenic influence is remarked by the presence of many ruderal species, as well as the presence of grapevine cultivars (*Vitis vinifera* L.), wild cabbage (*Brassica oleracea*), tomato (*Solanum lycopersicum*) and potatoes *Solanum tuberosum* L. as the areas near were agricultural ones.

Key words: Shkumbini river, riparian, flora, taxa, Elbasan

INTRODUCTION

The Shkumbin River basin lies entirely in the central area of Albania, which flow from the eastern slopes of the Valamara and Kamja mountain ranges. The 2445km² area of the watershed of the river is characterized by a deep valley in the upper part (Gjeta, 2014).

In the middle course of the river, in that part of the valley that coincides with the Elbasan plain, it begins to widen and the riverbed widens greatly, creating meanders. Shkumbini is one of the most erosive rivers in our country, with an average flow of suspended alluvium of about 187 kg/s (Kabo, 1998; Qirjazi, 2006).

Elbasan region has a **mediterranean climate, hot-summer** with an **average annual temperature** around 15 °C (Qiriazzi, 1998). Under the prevailing climatic and geographic conditions, the riparian floristic diversity of this section is predominantly characterized by woody vegetation, especially shrubs and tree species (Miho *et al*, 2005). Among these, willows (*Salix* sp.), alders (*Alnus* sp.), and poplars (*Populus* sp.) are the most representative taxa, reflecting their ecological adaptation to periodically flooded and moisture-rich habitats typical of riparian ecosystems (Naiman *et al.*, 2005; Tabacchi *et al.*, 2000).

The river waters are widely used in agriculture and industry with numerous irrigation canals built along the river whith two main canals located in our study area that have favored

the development of urban, agricultural and anthropogenic activities are: the Naum-Panxhi and Peqin-Kavajë canals (Pano, 2008).

This study was conducted to establish a general floristic list, with a particular focus on riparian areas of Elbasan (referring to Jagodinë, Murriqan and Shushicë villages) and Peqin (referring to Çengelaj, Paulesh, Broshkë villages) where urban development has had a noticeable impact. During our field trips we identified up to 254 plant taxa, belonging to 55 families, with the highest representation of Poaceae, Compositae, Fabaceae and Lamiaceae families, with respective percentages of 12%, 11%, 11%, 7% .

In relation to the studied areas, we observed a notable association between the floristic elements and their native taxa, indicating that the composition of the riparian vegetation is strongly shaped by the ecological and biogeographical conditions. The percentage of life-forms, follows hemicryptophytes with 22%, therophytes with 26%, and phanerophytes with 29%. The mediterranean elements, including eurimediterranean, submediterranean, and stenomediterranean are clearly distinguished in the chorological spectrum with the highest percentage that of 17%, which is followed by Cosmopolite with 6% and Balkanic 5%.

The study shows a clear predominance of native species, precisely 87%. In smaller proportions are cultivated and naturalised species with 5% and introduced species with 3%. Along the river, we collected taxa not typically associated with riparian zones such as: *Vitis vinifera* L., *Brassica oleracea* L., *Lycopersicon esculentum* Mill. and *Solanum tuberosum* L. which shows the anthropogenic influence.

MATERIAL AND METHOD

We collected data in the studied areas from March 2024 to the end of June 2025. The study areas included sites located along the river meanders near the settlements of Karinë, Çengelaj, Paulesh, Broshkë, Jagodinë (Figure 2), Murriqan, and Byshek. Plant samples were collected in growing seasons, date of the collection were recorded for each sample and photographs were taken from different parts of the samples.

Figure 2. Study site along the Shkumbini River near Jagodinë (N 41°04' 22.0" / E 20° 01' 02.5")

The plants were mostly identified directly in the field and the process is followed in the laboratory by using existing valid botanical sources such as: Albanian Flora Vol. I-IV (Paparisto *et al.*, 1988; Qosja *et al.*, 1992; 1996; Vangjeli *et al.*, 2000); European Flora Vol. I-V (Tutin *et al.*, 1964; 1968; 1972; 1976; 1980),); for the plant names and other data elaboration was used: Euro+Med 2024+, Chytrý *et al.*, 2024 etc. During fieldwork, the sites were visited and surveyed multiple times to collect additional data, as the areas are subject to ongoing urban disturbance, agricultural activities, and other human influences.

RESULTS AND DISCUSSION

During the study, a total of 254 plant taxa were identified in Elbasan and Peqin area. These taxa belong to 55 plant families, reflecting a high floristic diversity along the river. Some of the recorded plant taxa is presented in the table 1 (Figure 3, 4, 5, 6, 7 and 8).

Table 1. Some of the plant taxa present in the riparian environments of Peqin and Elbasan area

Figure 6. *Trifolium repens* L. Figure 7. *Arenaria serpyllifolia* L. Figure 8. *Vinca major* L.

The analysis of the collected data demonstrates that the *Poaceae*, *Compositae*, *Fabaceae*, *Lamiaceae* and *Brassicaceae* are the most prevalent families, highlighting their significant contribution to the floristic composition of the riparian zone (Figure 9). In the graphic below (Figure 9), we grouped under the category ‘Others’ all families represented by fewer than two taxa in the studied flora, in order to simplify the presentation and highlight the most representative families. The presence of these dominant families indicates that the riparian areas are characterized by high floristic diversity and ecological stability, reflecting vegetation well-adapted to Mediterranean conditions.

Figure 9. Graphic of systematic spectrum

The chorological spectrum in Figure 10 shows the presence of plants as following: Mediterranean (14%), EuMediterranean (17%), Steno-Mediterranean (5%), Paleotemperate (11%), Cosmopolite (6%), Eucaspian (4%), Circumboreal (4%), Balkanic (5%) elements with the respective percentages.

Figure 10. Chorological spectrum of the representative plant taxa

During our expedition, we observed that the areas along the river and between the cities are frequently utilized for anthropogenic purposes, particularly agriculture. According to the collected data, several taxa not typically associated with riparian zones were recorded, their occurrence explained by the influence of river meanders near urban settlements. Species such as: *Vitis vinifera* L., *Brassica oleracea* L., *Lycopersicon esculentum* Mill. and *Solanum tuberosum* L are referred to as ruderal, and their cultivated areas extend along the river, overlapping with the native riparian vegetation. Within the surveyed sites, the species spectrum is dominated by native taxa (87%), followed by cultivated and naturalised species (5%) and introduced species (2%).

Figure 11. Plant taxa status: native, naturalised, introduced and cultivated

The following figure (Figure 12) illustrates the life-form spectrum of the collected taxa. The life-form spectrum demonstrates how the dominant elements mirror plant adaptation to environmental constraints, particularly those shaped by climate and topography. The most abundant life-forms in these riparian areas are hemicryptophytes, phanerophytes, and therophytes. All other life-form categories are represented to a much lesser extent, as illustrated in the graphic, supporting the conclusion that these areas are predominantly occupied by native riparian plants, with a side influence from anthropogenic activities.

Figure 12. Life form of the collected plants

CONCLUSIONS

The riparian areas along the Shkumbin River represent highly diverse and ecologically dynamic habitats, supporting a wide range of plant taxa. The total plant taxa collected is 254 plants. The most representative families are Poaceae, Compositae, Lamiaceae and Fabaceae, which show a stronger influence on the floristic composition compared to the other families. The most abundant life-forms in these riparian areas are hemicryptophytes, phanerophytes, and therophytes. The presence of these life-forms in riparian areas shows the coexistence of species with different adaptive ability, reflecting the mediterranean climate and the ecological habitats in river banks. To complete the general overview of the collected data and the derived conclusions, we identified the chorological elements which influence the most, including mediterranean, stenomediterranean, eurimediterranean, cosmopolitan, and paleotemperate elements. The floristic survey recorded predominantly native species (87%), with smaller proportions of cultivated, naturalised and introduced species, reflecting both the natural character of the area and the influence of human activities. Ruderal species and cultivated plants are distributed along the river, intermingling with the native riparian vegetation, which indicates continuous anthropogenic influence, especially from agriculture and urban development. These data will be added to further studies of these environments, extended to different time periods such as summer and autumn, to provide a more complete presentation of them.

ABSTRACT

Rhododendron species, known for their striking flowers and foliage, are widely cultivated in temperate climates and are valued for their ornamental appeal. Pot cultivation of shrub or tree form Rhododendrons offers significant advantages for urban ornamental horticulture, particularly in limited spaces. Despite their aesthetic qualities, successful pot cultivation of Rhododendron species requires careful management due to their preference for acidic soil conditions and sensitivity to environmental stressors. In recent years, pot cultivation of Rhododendrons has gained popularity in Europe, as well as in parts of Asia and North America. However, there is currently no established commercial production in Turkey. This study examines selected horticultural practices related to the pot cultivation of Rhododendron species naturally occurring in Turkey, with a focus on propagation, microbial biostimulant application, and the use of pruning and growth regulators. Additionally, the study highlights the commercial potential of Rhododendrons and their suitability for balcony, terrace, and municipal landscape applications. Recommendations are also provided for future research and commercialization strategies.

Key Words: Woody ornamental plants, Adaptation, Propagation, PGRs, Microbial inoculants

INTRODUCTION

The genus *Rhododendron* (Ericaceae) represents one of the most species rich groups of woody ornamental plants, comprising 1,091 recognized species and natural hybrids according to the most recent taxonomic revisions (Royal Botanic Gardens, 2025). The native range of the genus extends from the temperate regions of the Northern Hemisphere to the tropical mountain zones of Asia, reaching as far as northeastern Australia (Lin et al., 2019). Within this global diversity, *Rhododendron* species are especially diverse in Asia, with nearly 600 species occurring in China and approximately 320 tropical *Vireya* species distributed across Southeast Asia and northeastern Australia (Chang et al., 2021). In Türkiye, the Eastern Black Sea Region constitutes the main center of diversity for the genus, where five native species *R. ponticum* L., *R. luteum* Sweet, *R. caucasicum* Pall., *R. smirnowii* Trautv., and *R. ungeronii* Trautv. are naturally distributed. Alongside these species, four naturally occurring hybrids have also been identified: *R. × sochadzeae* (*R. ponticum* × *R. caucasicum*), *R. × filidactylis* (*R. ponticum* × *R. ungeronii*), *R. × rosifaciens* (*R. smirnowii* × *R. ungeronii*), and *R. × davisianum* (*R. smirnowii* × *R. caucasicum*).

The genus *Rhododendron* comprises both evergreen and deciduous taxa, with most species growing as shrubs and a few attaining the stature of small trees. They are renowned for their large, showy flowers, which confer high ornamental and economic importance (Altun, 2021). Pot cultivation has attracted increasing attention in urban horticulture, particularly in East Asia, where studies such as those conducted on *Rhododendron* shrub communities in Nanjing highlight the practical use of these species in containerized urban greening (Guo et al., 2022). However, these blooms typically last only a few days to several weeks each year, making foliage the most consistently visible and enduring ornamental trait. Consequently, leaf morphology, color, texture, and variegation play a decisive role in determining the aesthetic and commercial value of cultivars, particularly in pot cultivation where compactness and year-round decorative qualities are highly desirable (Figure 1). Table 1 summarizes *Rhododendron* cultivars that are particularly valued for their ornamental foliage and their suitability for pot cultivation. Traits such as variegation, indumentum, seasonal color changes, and compact growth habit provide year-round decorative appeal, making these cultivars highly attractive for terrace, balcony, and nursery markets. For example, ‘Blattgold’ and ‘Goldflimmer’ are prized for their strong leaf variegation, while ‘Hydon Velvet’ and ‘Silbervelours’ are notable for their dense pubescence on the leaf underside, enhancing texture and visual depth. Cultivars such as ‘Wine and Roses®’ and ‘Rusty Dane’ add ornamental value through striking young leaf coloration and dense pubescence.

Figure 1. Selected *Rhododendron* cultivars with attractive foliage for pot cultivation (Schröder Rhododendron GmbH & Co. KG, 2023)

Cultivars distinguished by their ornamental foliage hold a central place in global pot cultivation markets: in Western Europe (Belgium, the Netherlands, Germany, and the United Kingdom), they dominate balcony and terrace landscaping; in East Asia (China, Japan, and South Korea), foliage diversity is closely tied to local garden traditions; and in North America (Oregon, Washington, and North Carolina), compact forms with striking leaves are preferred for nursery production. The widespread adoption of such cultivars underscores the global horticultural importance of foliage traits in potted *Rhododendron* production (RHS, 2023; JARS, 2021; Fine Gardening, 2022) (Figure 2).

Table 1. Rhododendron Cultivars with Ornamental Foliage and Suitability for Pot Cultivation
Information compiled from RHS (2023), JARS (2021), Fine Gardening (2022)

Cultivar	Leaf Characteristics	Pot Cultivation Traits
Blattgold	Dark green leaves with golden-yellow variegation.	Compact growth, highly decorative foliage for balcony and terrace pots.
Hydon Velvet	Underside densely covered with cinnamon-brown indumentum.	Compact form, velvety foliage enhances ornamental value in containers.
Goldflimmer	Green leaves with golden-yellow central variegation.	Strong foliage contrast, ideal for ornamental pot cultivation.
Graziella	Narrow, lanceolate glossy green leaves.	Elegant foliage, suitable for modern container displays.
Elizabeth	Young leaves showing reddish-brown tones.	Seasonal color change enhances decorative value in pots.
Silbervelours	Underside covered with silvery hairs, velvety appearance.	Unique foliage texture, attractive in pot displays.
Queen Bee	Rusty-brown tomentum on the underside.	Compact growth habit suitable for limited-space container cultivation.
Wine and Roses®	Young leaves reddish-purple, strong ornamental contrast.	High visual appeal in pot culture due to leaf color contrast.
<i>Rh. roxieanum</i> var. <i>oreonastes</i>	Needle-like narrow leaves with distinctive venation.	Exotic foliage form, suited for collectors' container displays.
<i>Rh. taliense</i> 'Honigduft'	Underside densely hairy with pale indumentum.	High ornamental foliage value, suitable for pot cultivation.
Rosa Perle	Small glossy green leaves, compact growth.	Compact form, ideal for small decorative pots.
Rusty Dane	Rusty-brown indumentum on the underside.	Distinctive leaf texture, strong ornamental potential in pots.

Figure 2. Global pot cultivation areas of *Rhododendron* spp. green shading indicate the main production centers in Europe (Belgium, Netherlands, Germany, United Kingdom, Poland, Czech Republic), orange shading indicates Asia (China, Japan, South Korea), and purple shading indicates North America (USA: Oregon, Washington, North Carolina). The map was prepared by the authors based on horticultural production reports.

Building upon the general information presented above regarding Rhododendron species woody plants exhibiting shrub or tree forms the subsequent sections explore the cultivation requirements for container-grown plants, key production challenges, and emerging approaches. The overall production potential is assessed through a combination of theoretical insights and practical experiences, with a particular emphasis on applications conducted in Türkiye.

1.1. Propagation and Rooting

1.1.1. The Role of Plant Growth Regulators (PGRs)

Propagation techniques are particularly critical in pot production, where uniformity, rooting efficiency, and plant quality determine commercial success. Likewise, cutting experiments showed that genotype, auxin type, and substrate composition strongly affect adventitious rooting, with IBA applied in peat–perlite substrates producing the best results across several cultivars (Ferus et al., 2017). Plant growth regulators (PGRs) further enhance production efficiency. Paclobutrazol reduces shoot elongation, improves compactness, and stimulates branching (Ranney et al., 1994), while thidiazuron (TDZ) and naphthaleneacetic acid (NAA) have been effective in in vitro regeneration systems (Wu et al., 2023). Recent studies reported that NAA was superior to IBA for rooting success in *R. micranthum* cuttings (Oh et al., 2023), whereas IBA remained more effective than IAA for adventitious rooting in *R. fortunei* (Wei et al., 2018). TDZ combined with optimized LED lighting improved microshoot proliferation and metabolite accumulation in *R. mucronulatum* (Zaytseva et al., 2023). Air-layering experiments on Turkish native species (*R. ponticum*, *R. luteum*, *R. unguernii*, *R. caucasicum*) demonstrated that both indole-3-butyric acid (IBA) concentration (0, 500, 1500 ppm) and season significantly affected rooting parameters, including root length, volume, diameter, and dry weight. The highest rooting efficiency (100%) was obtained for *R. unguernii* and *R. caucasicum*, particularly in autumn with 1,500 ppm IBA (Altun, 2023) (Table 2).

1.1.2. The Role of Microbial Inoculants

Alongside PGRs, beneficial microorganisms are increasingly recognized as sustainable tools in containerized rhododendron production. Ericoid mycorrhizal fungi (*Oidiodendron maius*) accelerate rooting and nutrient uptake in *R. fortunei* and *R. ovatum* (Wei et al., 2016, 2020). Long-term inoculation studies further improved N, P, and Ca accumulation in containerized cultivars (*R. hybridum* ‘Anneke’) (Jarosz, 2021). Endophytic bacteria such as *Pseudomonas lurida* and *Bacillus velezensis* produce IAA and GA, increase phosphorus solubilization, and suppress fungal pathogens, underscoring their dual role as PGPR and biocontrol agents (Biswas et al., 2024). Similarly, bio-based fertilizers enhanced soil microbial activity and growth in potted azaleas (*R. simsii*) (Teng et al., 2024) (Table 2).

Table 2. Effects of PGRs and Microbial Inoculants on Rooting and Propagation of Rhododendrons in Pots

Topic	Key Findings	Cultivar / Material	Reference
In vitro regeneration & PGR optimization (TDZ+NAA)	High shoot proliferation and rooting achieved with TDZ+NAA; efficient protocol.	<i>R. decorum</i> (flower bud explants)	Wu et al., 2023, Horticulturae
Auxin effects on cutting propagation	NAA (150–250 mg/L) superior to IBA in rooting %, root traits, survival.	<i>R. micranthum</i> (stem cuttings)	Oh et al., 2023, Horticulturae
Microshoot rooting response to auxins	IBA more effective than IAA for adventitious rooting in vitro.	<i>R. fortunei</i>	Wei et al., 2018, Industrial Crops & Products
TDZ + LED effect on microshoot culture	0.5 µM TDZ + LED increased shoot proliferation and biomass; 0.1 µM TDZ + LED enhanced accumulation of taxifolin, rutin, and other phenolics in <i>R. mucronulatum</i> microshoots	<i>R. mucronulatum</i>	Zaytseva et al., 2023, J. Plant Growth Regulation
Effect of ErM (<i>Oidiodendron maius</i>)	Accelerated rooting; IAA/Trp pathways activated.	<i>R. fortunei</i> (microcuttings)	Wei et al., 2020, Horticulture Research
Nutritional contribution of ErM (3 years)	Increased N, P, Ca uptake in container culture.	<i>R. hybridum</i> ‘Anneke’	Jarosz, 2021, Agriculture
PGPR endophytes	<i>Pseudomonas</i> & <i>Bacillus</i> isolates produced IAA/GA, showed antifungal activity.	<i>R. griffithianum</i> , <i>R. arboreum</i>	Biswas et al., 2024, Current Microbiology
Microbial fertilizer	Improved soil biology and plant performance.	Azalea ‘Carnation’	Teng et al., 2024, Frontiers in Microbiology
Plant Growth Regulators (Paclobutrazol)	Paclobutrazol reduces shoot elongation, ensures compact form; promotes flowering.	Potted <i>Rhododendron</i> spp.	Ranney et al., 1994
Air-layering + IBA	IBA (0–1500 ppm) and season significantly influenced rooting.	<i>R. ponticum</i> , <i>R. luteum</i> , <i>R. unguernii</i> , <i>R. caucasicum</i>	Altun, 2023, BioResources
Auxin/substrate & genotype effects	IBA + peat/perlite substrate → higher rooting success depending on genotype/time.	Various <i>Rhododendron</i> spp.	Ferus et al., 2017, J. Applied Horticulture

1.2. Cultivation Practices

Successful propagation and cultivation of *rhododendrons* in pots requires specialized practices, as these species are highly sensitive to substrate pH; neutral to alkaline conditions often impair root development and overall growth performance. These plants inherently thrive in acidic soils typically within a pH range of 5.0 to 6.0 but exhibit significant stress responses when grown in neutral to slightly alkaline conditions (Turner et al., 2020). High pH

environments adversely affect root morphology and limit nutrient uptake, leading to reduced growth, chlorosis, and lower survival rates. Greenhouse studies reinforce these findings, showing that neutral pH substrates (e.g., pH 6.3) result in stunted root and shoot growth, chlorophyll reduction, and impaired overall health in *R. fortunei* hybrids (Wang et al., 2023). Water management strongly affects pot production. Koniarski and Matysiak (2013) showed that regulated deficit irrigation (RDI) at 75% ETp produced the highest visual quality, while moderate deficits enhanced bud formation and compactness without negatively affecting photosynthesis. This suggests that controlled irrigation can serve as a practical alternative to pruning and PGRs while conserving water. French and Alsbury (1986) reported progress on forcing *rhododendrons* as pot plants under controlled greenhouse conditions. Unlike earlier work that relied on supplementary lighting and growth regulators, their approach utilized naturally budded plants grown over two seasons, followed by forcing at higher temperatures (21/18 °C, day/night). This method significantly shortened the forcing period, allowing flowering up to three weeks earlier than previous trials, with plants blooming in time for Valentine's Day. The study highlighted the potential of producing high-quality potted *rhododendrons* with flowers on nearly every shoot, while reducing reliance on growth regulators and heated greenhouse space, thereby offering a commercially viable production strategy (Table 3).

Table3. Academic Studies on Rhododendron Cultivation in Pots

Topic	Key Findings	Cultivar/Material	Reference
Irrigation (RDI)	Controlled water deficit (50–75% ETp) makes plants more compact and aesthetic; can enhance flowering; saves water.	'Catawbiense Boursault', 'Old Port'	Koniarski & Matysiak, 2013
Substrate and pH management	Acidic medium (pH 4.5–5.8) is suitable for growth and bud set; high pH may cause Fe chlorosis.	Various <i>Rhododendron</i> species	Turner et al., 2020; Wang et al., 2023
Photoperiod / Forcing	Naturally budded plants forced in greenhouse flowered 3 weeks earlier.	<i>R. simsii</i> , other hybrids	French & Alsbury, 1986

1.3. Recent Advances in Propagation

In recent years, grafting has emerged as an alternative propagation technique for potted *Rhododendron* production, particularly in commercial nurseries. As shown in Figure 3, selected cultivars (e.g., 'Alfred') are grafted onto vigorous rootstocks such as 'Cunningham's White'.

Figure 3. Sequential steps of grafting-based propagation of *Rhododendrons*, including scion and rootstock preparation, tying, rooting, and transplanting into nursery beds (Schröder Rhododendron GmbH & Co. KG, 2023)

After the graft union is secured, the young plants are transferred to rooting beds where initial root formation occurs, followed by transplantation into pots under controlled nursery

conditions. Compared with conventional cutting propagation, grafting offers higher uniformity, improved stress tolerance, and greater adaptation to intensive production systems, making it an increasingly preferred method in modern horticultural practice.

1.4. Pot Cultivation Research in Northeastern Türkiye

In Türkiye, native rhododendrons are among the most characteristic elements of the Eastern Black Sea flora; however, no studies have so far focused on their propagation and pot cultivation. To address this gap, a BAP-supported project was initiated with the aim of developing preliminary protocols for the containerized production of native species under controlled conditions. Within the scope of the project, plant materials of five native species (*R. ponticum* L., *R. luteum* Sweet, *R. caucasicum* Pall., *R. ungerii* Trautv., and *R. smirnowii* Trautv.) were collected from natural populations in Artvin, Rize, and Trabzon provinces during the spring and autumn seasons of 2023–2024.

To overcome the well-known challenges in rhododendron propagation, the project combines both ex vitro and in vitro approaches. In ex vitro trials, shoot cuttings were subjected to different rooting strategies, including auxin (IBA), mycorrhiza, rhizobacteria, and their combinations, and then planted in peat–perlite mixtures under greenhouse conditions. In vitro micropropagation experiments were conducted using shoot tip explants, with various sterilization protocols evaluated to minimize contamination. In addition, culture media supplemented with BAP, 2-iP, and IBA are being tested for their effects on shoot initiation, multiplication, and rooting. Furthermore, paclobutrazol applications are being carried out on rooted cuttings to obtain compact plants suitable for pot production. Different doses and application methods (dipping, soil drench, foliar spray; with and without pinching) are being evaluated in terms of their effectiveness in controlling plant height, increasing leaf number, thickening stem diameter, and promoting compact plant form.

This project represents the first research in Türkiye to investigate the pot cultivation potential of native rhododendrons. Although the trials are still ongoing, the study is expected to provide a foundation for future conservation-oriented research and to create new opportunities for the ornamental plants sector.

CONCLUSIONS

Rhododendrons are a group of woody ornamentals of high ecological significance and remarkable ornamental value. In Türkiye, particularly in the Eastern Black Sea Region, the natural diversity of these species represents both a genetic resource to be conserved and an underutilized potential for the ornamental plant sector. However, their commercial-scale pot production has remained limited due to rooting difficulties, susceptibility to abiotic stresses, and the absence of standardized cultivation practices.

The existing body of research provides valuable insights into propagation techniques, growing media, irrigation and fertilization management, and the role of growth regulators. Nevertheless, most of these studies have focused on a limited number of taxa or specific cultivation aspects, leaving major gaps in comprehensive protocols that could support commercial production. In recent years, the use of microbial biostimulants, growth regulators such as paclobutrazol, and advances in in vitro culture systems have emerged as promising strategies to overcome these challenges.

In this context, the ongoing BAP-supported project in Türkiye represents a systematic attempt to develop pot cultivation protocols for native rhododendrons by integrating ex vitro

cutting propagation, in vitro micropropagation, and paclobutrazol-based growth regulation. Although the trials are still in progress, this work provides an important foundation for future studies.

ACKNOWLEDGEMENT

This research was funded by the Recep Tayyip Erdoğan University Scientific Research Projects Coordination Unit (BAP), grant number FBA-2023-1498.

ABSTRACT

This study is designed to promote the Algerian sector specializing in the production of essential oils by highlighting the pharmacological potential of certain essential oils, including *Daucus carota* L., produced by a unit located in the wilaya of El Taref (El Kala region) called Flor' Est. The antioxidant activity was assessed using the DPPH free radical method. Free radical scavenging activity was measured by mixing 100 µL of each of the methanolic solutions of the tested essential oils at different concentrations with 1300 µL of a methanolic solution of DPPH (0.004%). After a 30-minute incubation period at room temperature, the absorbance was read at 517 nm. The inhibition of the DPPH free radical by ascorbic acid was also analyzed for comparison.

Our results show that the antioxidant activity increased with increasing concentrations. It seems that vitamin C (ascorbic acid) is the most effective and powerful antioxidant than the essential oil studied with a value of 0.0056 mg/ml. The IC₅₀ of *Daucus carota* L. equal to 14.11 mg/ml. The search for active molecules with low side effects is essential. Such molecules are present in plants that sometimes constitute the only source of treatment for poor populations. This work has revealed the importance of *Daucus carota* L. species, which deserve an honorable place in Algerian medicine.

Keywords: *Daucus carota* L., Essential oil, Antioxidant activity.

INTRODUCTION

Aromatic plants are promising and constitute a great source of natural antioxidants for the food industry. Indeed, the oxidation of lipids in food products not only induces a reduction in the nutritional value of the food, but also has effects recognized as harmful for the consumer and which can be associated with risks of century diseases in humans. The negative effects of synthetic antioxidants encourage their replacement by natural agents.

The antioxidant phytochemicals from plants, particularly essential oil components, flavonoids, and other polyphenols, have been reported to inhibit the propagation of free radical reactions, to protect the human body from disease (Kinsella et al., 1993 ; Terao et al., 1997). *Daucus* is a worldwide genus of herbaceous plants of the family Apiaceae of which the best-known species is the cultivated carrot. The genus comprises about 20 species divided into five sections (Saenz et al., 2003).

The genus *Daucus* appears to have its center of dispersion in the Mediterranean Region, particularly in North Africa, where strong speciation has taken place. Except the common carrot *D. carota* L., which is cultivated throughout the world, there is one Australian species, naturalized also in Europe and three other species in the American continent; all others are

Mediterranean species (Saenz et al., 2003). *Daucus carota* has been subject to several investigations (Flamini et al., 2003).

Traditionally, Carrot Essential Oil “CEO” is used to treat urinary calculus, cystitis, gout, and lithuria (Thomas et al., 2001). CEO also has anti-tumor, anti-cancer properties, and antioxidant activity against a wide range of malignancies and diseases (Tawil et al., 2015). Many of the medicinal properties are claimed for Iran’s wild *D. carota*, characterized with nephroprotective, wound healing, and aphrodisiac activity (Bahrami et al., 2018).

Previous studies dealing with members of this genus revealed that the main constituents were: sabinene with monoterpene hydrocarbons for *D. carota* ssp. *gummifer* from Spain, whereas α -pinene with monoterpene hydrocarbons predominated in *D. carota* ssp. *carota* from Poland. However, monoterpene hydrocarbons (α -pinene, limonene, and sabinene) were dominating in *D. muricatus* and *D. sahariensis* from Algeria (Zaibet et al., 2015).

The chemical composition of the essential oils of *D. aureus* from Western Algeria has also been previously reported (Meliani et al., 2013). The oils were characterized by the presence as main components of sesquiterpene hydrocarbons (54.3%) in the aerial parts (Table 1).

The aim of our study is to promote the Algerian sector specializing in the production of essential oils by highlighting the pharmacological potential of certain essential oils, including *Daucus carota* L., produced by a unit located in the wilaya of El Taref (El Kala region) called Flor'Est.

MATERIAL AND METHOD

Plant material

The species *Daucus carota* L. was harvested in the region of El Taref (northeastern Algeria) in April 2023. The identification of the plant was done with the key to determining the flora of Quezel and Santa (Quezel et al., 1963). Specimens were kept at the Laboratory Medical Botany, Department of Pharmacy, Faculty of Medicine Annaba-Algeria.

Essential oil

Essential oil of *Daucus carota* L. has been procured from production unit of essential and vegetable oils "Elexir Est" Algeria.

Determination of antioxidant activity with 2,2-di-phenyl-1-picrylhydrazyl (DPPH) method

Free radical scavenging ability of essential oil was measured from the bleaching of a purple-coloured methanol solution of DPPH. Based on a pre-examination, ten concentrations are used. The DPPH solution was prepared by solubilizing 0.4 mg of DPPH in 100 ml of methanol. Briefly, 1300 μ L of a 0.4 mg/100ml solution of DPPH radical in methanol was added to 100 μ L of essential oil at different concentrations. The mixture was shaken vigorously for 1min by vortexing and left to stand at room temperature in the dark for 30min. Absorbances were measured at 517nm with a spectrophotometer against a blank. Ascorbic acid was used for comparison as standard antioxidants. The percentage inhibition of activity was calculated as :

$$\% \text{Inhibition} = [(A_{\text{blank}} - A_{\text{sample}}) / A_{\text{blank}}] \times 100.$$

Where A_{blank} is the absorbance of the control and A_{sample} is the absorbance of the test extract. IC_{50} value (mg/mL) is the concentration of the sample scavenging 50% of the DPPH radical (Ounaissia et al., 2021).

Figure 1. Operating protocol

RESULTS AND DISCUSSION

The results of the antioxydant activity are shown in Figure 2.

Figure 2. Percentage of DPPH free radical scavenging by *Daucus carota* L. essential oil

The results obtained by our study carried out on the species of *Daucus carota* L., are divergent from those of (Ihamdane et al., 2021) found a value of $IC_{50} = 0.073$ mg/ml. In our study, it was found that the radical scavenging activity expressed by the IC_{50} value was 14.11 mg/ml. This value is better than the results obtained in another similar study, which found an IC_{50} value of 30.5 mg/ml. (Sbai el otmani et al., 2018). Our results are in agreement with those of (Zafar et al., 2021) who affirm the antioxidant activity of *Daucus carota* L. essential oil, with an inhibition rate of 74% (74.61% in our study). In another study on the chemical composition and antioxidant activity of Essential Oil and methanolic extract of Algerian Wild Carrot *Daucus carota* L. subsp, the results showed that Wild Carrot Essential Oil has significant antioxidant activity (Ksouri et al., 2014).

Lebanon wild carrot essential oil extract from the dried mature umbels exhibited antioxidant activity in all the assays (DPPH, FIC, and FRAP assays). The IC_{50} value for the DPPH assay was determined to be 2.1 mg/mL. Nevertheless, it was a weaker antioxidant in comparison to Trolox (IC_{50} value of 0.18 mg/mL) (Shebaby et al., 2013). carrot essential oil from Lebanon wild plants is characterized by significant antioxidant properties (DPPH activity, $IC_{50} = 0.29$ mg/mL) (Shebaby et al., 2015).

The carrot essential oil from Algerian carrot leaves and seeds were found to be effective antioxidants in several in vitro assays. The carrot leaf extract provided the highest radical-scavenging activity, with lower IC_{50} values (83 mg/mL) than seeds (136 mg/mL). The antioxidant activity of the CEO was lower than that of the synthetic antioxidant ascorbic

acid (IC_{50} value of $3.73\mu\text{g/mL}$) (Ihamdane 2021). The tested EOs from Moroccan *D. carota* demonstrated a low antioxidant potential ($IC_{50} = 73.31\text{ mg/mL}$) (Ihamdane et al., 2021).

The essential oil from Oum Elbouaghi (Algeria) revealed the lowest antioxidant activity, $IC_{50} = 970 \pm 0.53\text{ }\mu\text{g/mL}$; the values for the Setif and Constantine sites were 713 ± 0.047 and $783 \pm 0.16\text{ }\mu\text{g/mL}$, respectively.

This variation in antioxidant activity can be attributed to the chemical composition of the essential oils. It has been reported that components with phenolic structures such as thymol or carvacrol, were responsible for the antioxidant activity of many essential oils and a scant antioxidant activity is given to monoterpene and sesquiterpene hydrocarbons (Teixeira et al., 2013 ; Rubberto et al., 2000).

Other factors, mainly related to the species, may interact: the season and location of the plant harvest, the part distilled, and the extraction protocol for these secondary metabolites.

CONCLUSIONS

Plant extracts have great potential as antioxidant compounds. Thus, they can be proposed as a natural additive in food industry to increase the shelf life of food stuffs and in pharmaceutical industries. The results of this study suggest that *Daucus carota* L. essential oil possesses antioxidant properties.

This result suggests that the essential oil from *Daucus carota* have a potential use in the food industry as food preservative. Nevertheless, further studies are needed to explore other bioactivities of *D. carota* essential oil and to elucidate also the composition of non-volatile compounds.

ABSTRACT

Almond is a major nut crop cultivated extensively worldwide due to its high nutritional value and significant economic importance. However, conventional propagation methods have limitations, such as slow production rates, low rooting efficiency, and high risk of pathogen transmission. Micropropagation is an effective biotechnological tool that enables the rapid production of genetically uniform, disease-free, and high-quality plant material. This review examines the protocols reported in the literature on the micropropagation of almond and almond × peach hybrid genotypes. Explant types, medium composition, plant growth regulators, sterilization procedures, and culture conditions are comprehensively evaluated for their effects on propagation success. Evidence indicate that cytokinins (BA, TDZ) and auxins (IBA, NAA) play critical roles in shoot proliferation and rooting, although success rates vary considerably among genotypes. Additionally, light regimes, carbohydrate sources, and hormone optimization have been identified as crucial determinants of propagation efficiency. This review highlights the need for standardized, genotype-specific, and highly efficient protocols and is expected to guide future micropropagation studies on almond and its hybrids.

Keywords: Almond, auxins, cytokinins, **genotypic effect**, micropropagation, plant growth regulators

INTRODUCTION

Almond (*Prunus dulcis* Mill.), belonging to the subgenus *Amygdalus* of the genus *Prunus* (Rosaceae), is commercially cultivated worldwide (Madam et al., 2011). It is believed to have originated in the arid mountainous regions of Central Asia (Ladizinsky, 1999). Almond, one of the oldest domesticated fruit tree species, was first cultivated nearly 4,000 years ago in Iran, Türkiye, Syria, and Palestine, from where it spread to Greece, North Africa, and Italy, and later was introduced to North America by early settlers (Kester & Asay, 1975). Almonds are grown economically between latitudes 30–44° in the Northern Hemisphere and 20–40° in the Southern Hemisphere, at altitudes of 600–1000 m (Özbek, 1978).

Breeding programs in perennial fruit trees require decades to accomplish due to the long juvenile phase and high labor intensity. Such efforts are highly demanding, continuous, and costly. Considering the juvenile sterility of fruit trees, breeding studies in horticultural crops often take 20–25 years and require large experimental areas. Thus, the use of biotechnological approaches has become a necessity rather than a choice (Balık, 2024). Micropropagation, allowing rapid clonal multiplication under controlled conditions, is recognized as a

breakthrough technique in horticultural plant production. The method involves culturing plant cells or tissues under sterile and nutrient-rich media. The main advantages of micropropagation include year-round rapid propagation of cultivars, elimination of diseases, maintenance of genetic stability, suitability for large-scale commercial production in limited space, and conservation of rare genotypes. Moreover, the ability to manipulate growth conditions enhances propagation efficiency. Therefore, micropropagation emerges as a strategic biotechnological approach for meeting global demand for high-quality plant materials (Meena et al., 2024).

The aim of this review is to analyze research studies on the micropropagation of almond and almond $\times$ peach hybrids reported in the literature. Different protocols, medium compositions, plant growth regulators, and genotypic influences on micropropagation efficiency are discussed. Furthermore, recent advances in this field are compiled to provide a comprehensive perspective that can guide both researchers and practitioners.

STUDIES ON THE MICROPROPAGATION OF ALMOND AND ALMOND $\times$ PEACH HYBRID GENOTYPES

Rugini and Verma (1983) developed an effective *in vitro* protocol to achieve rapid clonal multiplication from the difficult-to-root almond cultivar 'Ferragnes'. Shoot tips measuring 0.4–0.7 mm were used, and ~55% of the multiplied shoots were successfully rooted *in vitro* and transferred to soil. At initiation, shoots were maintained for 3–4 consecutive subcultures on a medium promoting slow growth, then transferred to Murashige and Skoog (MS) medium (0.9% agar, 0.7 mg L⁻¹ 6-benzylaminopurine, BAP; 0.01 mg L⁻¹ α -naphthaleneacetic acid, NAA). Under these conditions, up to sixfold proliferation per shoot was obtained at 20-day subculture intervals and sustained for at least 24 months. Shoot elongation was promoted by reducing BAP to 0.2 mg L⁻¹ and omitting NAA. Shoots were divided into microcuttings with 2–3 leaves for rooting trials. Rooting was achieved on Bourgin and Nitsch (BN) medium with macronutrients halved, solidified with 0.9% agar and supplemented with either 1 mg L⁻¹ NAA or 1 mg L⁻¹ indole-3-butyric acid (IBA). Root induction proceeded rapidly in darkness with ~55% success. Subsequent root development was completed in liquid medium without auxin, with sterile vermiculite as a support. A proportion of the plantlets was successfully acclimatized to soil conditions. Kamali et al. (2001) sought to facilitate clonal propagation of the rootstock GF-677 via tissue culture. Shoot tips collected in April were surface-sterilized with mercuric chloride. The most suitable culture medium was a modified Knop formulation, and 1 mg L⁻¹ BA yielded the highest multiplication. The greatest rooting percentage occurred on LS medium containing 0.3 mg L⁻¹ NAA and 1.6 mg L⁻¹ thiamine when shoots were exposed to 7 days of darkness. Multiplied plantlets were first transferred to Jiffy-7 and then to pots. Channuntapipat et al. (2003) investigated *in vitro* shoot proliferation in almond cultivars Nonpareil 15-1 and Ne Plus Ultra, and the almond $\times$ peach hybrid rootstock Titan $\times$ Nemaguard. Shoot tips (~0.7 cm, 3–5 leaves) were cultured on suitable proliferation media. For Nonpareil 15-1, the best response was on MS (pH 5.7) containing 0.049 mM IBA, 3 mM BAP, 0.058 M sucrose and 0.7% agar. For Ne Plus Ultra, optimal proliferation was obtained on MS (pH 5.7) with 0.049 mM IBA, 5 mM BAP, 0.088 M sucrose and 0.7% agar. For Titan $\times$ Nemaguard, the highest multiplication occurred on MS with 10 mM BAP, 0.088 M sucrose and 0.7% agar. Shoots (~2 cm) of the rootstock rooted at 88% on half-strength MS (pH 5.7) with 2.4 mM IBA, 0.088 M sucrose and 0.7% agar after 1 week in darkness plus 2 weeks in light. Micrografts (~1.5 cm) onto the rootstock survived at 50% (Nonpareil 15-1) and 65% (Ne Plus Ultra). Rooted stocks and micrografts were acclimatized successfully, with 92% survival after transfer to potting mix. Antonopoulou et al. (2005) assessed riboflavin (vitamin B₂) for *in vitro* rooting of the almond $\times$ peach hybrid rootstock GF-677, testing 0 (control), 0.5, 1.0, 1.5 and 2.0 mg L⁻¹. After four weeks, riboflavin did not stimulate rooting; rooting frequencies were

markedly lower than the control, and chlorosis with apical necrosis appeared at the two highest concentrations. Morini and Perrone (2006) evaluated a short light/dark regime (4 h light/2 h dark) on rooting in several fruit rootstocks: GF-677 (peach × almond), Mr.S. 2/5 (*Prunus cerasifera*), MM 106 (apple; Northern Spy × Paradise M1) and BA 29 (*Cydonia oblonga*). Controls received a 16 h light/8 h dark photoperiod. Under 4/2 cycling, 100% rooting was achieved in GF-677, Mr.S. 2/5 and MM 106. In BA 29, short cycles increased rooting by ~65%. All rootstocks under 4/2 exhibited higher root numbers and lengths and rooted ~4–5 days earlier than controls. In BA 29, 0.2 mg dm⁻³ IBA under 4/2 yielded rooting equivalent to 0.4 mg dm⁻³ IBA under 16/8. The authors concluded that 4/2 cycles enhance auxin effect and promote rhizogenesis. Kamali et al. (2006) determined optimal media for micropropagation of GF-677 and almond seedlings. For GF-677, the best multiplication occurred on modified MS with 0.7 mg L⁻¹ BA + 0.01 mg L⁻¹ NAA, whereas seed genotypes performed best on MS with 1 mg L⁻¹ BA + 0.01 mg L⁻¹ NAA. Shoot elongation of GF-677 was maximized on modified Knop with 0.1 mg L⁻¹ BA, while seed genotypes elongated better on modified MS with the same BA level. Rooting of GF-677 reached up to 80% on LS with 0.3 mg L⁻¹ NAA in darkness. By contrast, rooting in seed genotypes was problematic both conventionally and *in vitro*. Neslihan (2007) aimed to establish an efficient *in vitro* regeneration protocol for GF-677. Nodal explants were cultured on MS with BA (0.5–2.0 mg L⁻¹). High shoot induction and tillering occurred particularly on MS with 1 mg L⁻¹ BA. Young leaves from *in vitro* shoots were cultured on MS with TDZ or BA alone or combined with NAA. Pronounced white callus formed at shoot bases, and adventitious shoots regenerated from these calli were transferred to MS containing 0.0, 0.1 or 0.5 mg L⁻¹ BA for elongation. The most effective elongation medium was MS with 0.5 mg L⁻¹ BA, 30 g L⁻¹ sucrose and 5.5 g L⁻¹ agar. Elongated shoots were rooted on ½ MS with 0.05–2.0 mg L⁻¹ IBA; 1 mg L⁻¹ IBA yielded 84.2% rooting and 66.4% acclimatization. Akbaş et al. (2009) developed an *in vitro* shoot-multiplication protocol for the cultivar ‘Yaltsinki’ using apical shoot tips from mature trees. Explants were cultured on MS with various BA and kinetin levels. The highest multiplication (16.10 shoots per explant) was obtained on MS with 30 g L⁻¹ sucrose, 7 g L⁻¹ agar and 1.0 mg L⁻¹ BA—the most effective BA level for multiple shoot induction. Combining 1.0 mg L⁻¹ BA + kinetin with three auxins (IAA, IBA, NAA at 0.25–0.5 mg L⁻¹) showed that NAA suppressed new shoot formation, whereas 1.0 mg L⁻¹ BA + 0.5 mg L⁻¹ IAA yielded 11.25 shoots per explant. Among sucrose concentrations (20–50 g L⁻¹), 30 g L⁻¹ gave the best result (15.40 shoots per explant). Sevgin (2010) optimized rooting in the micropropagation of economically important but difficult-to-root almond cultivars (Nonpareil, Ferragnes, Tuano) alongside GF-677. Meta-topolin (mT) outperformed BA for shoot number and length. Rooting was not achieved in Ferragnes and Nonpareil. The highest rooting (64%) occurred in GF-677 on 1 mg L⁻¹ IBA. Phloroglucinol did not improve rooting but promoted shoot growth. Rooting peaked (67%) at the eighth subculture. Dejampour et al. (2011) developed an efficient micropropagation protocol for the almond × peach rootstock HS314, proposed as an alternative to GF-677. Surface-sterilized nodal explants were cultured on modified DKW with 3% sucrose, 100 mg L⁻¹ phloroglucinol, 0.7% plant agar and 0.5 mg L⁻¹ BAP, then transferred to combinations of 0.5–2.0 mg L⁻¹ BAP and 0.0–0.5 mg L⁻¹ IBA. Maximum shoot number occurred at 2.0 mg L⁻¹ BAP. For rooting, shoots were placed on DKW with 0.5–4.0 mg L⁻¹ IBA or NAA; 2.0 mg L⁻¹ IBA yielded the greatest root number and length. Halving DKW salts increased rooting from 66% to 85%. Rooted plantlets were acclimatized with high success. Sharifmoghaddam et al. (2011) optimized micropropagation of GF-677. After sterilizing actively growing shoots, explants were cultured on MS with various regulator combinations. After four weeks, data on callus formation, multiplication rate, shoots per explant and shoot length were recorded. MS + 0.01 mg L⁻¹ IBA + 2.0 mg L⁻¹ BA was optimal for initiation and proliferation. Autumn was identified as the best season for explant collection. Rooting was highest on MS with 0.5 mg L⁻¹ IBA. Özbek (2011) achieved clonal multiplication

from shoot tips in the rootstocks ‘Garnem’, GF-677, ‘Cadaman’ and ‘Myrobalan 29-C’ under *in vitro* conditions and evaluated resistance of regenerated plants to root-knot nematodes (*Meloidogyne incognita*, *M. javanica*). S and modified MS (MST) media were used with constant 0.05 mg L⁻¹ GA₃ and BAP at 0–2.0 mg L⁻¹. Substantial differences were reported among clones in multiplication capacity and nematode resistance. Ünek et al. (2011) studied *in vitro* multiplication potential of the clonal hybrid rootstock ‘Garnem’, using apical and axillary buds on MS with BAP, kinetin (Kin), 2iP and TDZ at various concentrations under 24 ± 2 °C, 16-h photoperiod and 3000–4000 lux. Plant growth regulators significantly affected proliferation; the highest shoot number occurred with 1.0 mg L⁻¹ BAP, whereas higher BAP reduced the multiplication coefficient. Aghaye and Yadollahi (2012) optimized the micropropagation of GF-677 on MS with BAP at 0–2.0 mg L⁻¹ (five replicates per treatment). BAP at 1.0 mg L⁻¹ produced significantly greater shoot number (2.98) and shoot length than other concentrations and control (shoot number 0.4). Shoots (3–5 cm) were rooted under various treatments; the highest rooting occurred on 3 mg L⁻¹ IBA (mean 2.167 roots; 11.53 cm root length). A one-week dark pre-treatment improved rooting relative to continuous light. Abbasi et al. (2019) examined micropropagation of *P. scoparia* using nodal segments (3–5 cm) sterilized with 10% sodium hypochlorite. For proliferation, explants were cultured on MS with 7.0 g L⁻¹ agar, 30.0 g L⁻¹ sucrose and BA at 0–4.0 mg L⁻¹ or TDZ at 0–7.0 mg L⁻¹. Shoot proliferation occurred only at 2.0 and 4.0 mg L⁻¹ BA and at 2.0 mg L⁻¹ TDZ, with the latter giving the highest shoot number, leaf number and leaf color quality. For rooting, shoots (2–3 cm) were transferred to ½ MS with 30.0 g L⁻¹ sucrose, 7.5 g L⁻¹ agar and IBA or NAA at 0–1.0 mg L⁻¹. IBA significantly affected rooting percentage, root number and length; the best response was at 0.50 mg L⁻¹ IBA, whereas other IBA levels and all NAA treatments failed to induce roots. Thus, MS + 2.0 mg L⁻¹ TDZ for multiplication and ½ MS + 0.50 mg L⁻¹ IBA for rooting are recommended for *P. scoparia*. Ritterbusch et al. (2020) addressed *in vitro* propagation of the almond × peach hybrid rootstock G × N-9, valued for resistance to several *Meloidogyne* spp. While autumn hardwood cuttings were recommended, demand increased for *in vitro* propagation. The study evaluated BAP and kinetin (KIN), carbon sources (sucrose, sorbitol) for proliferation/elongation, and IBA for rooting and acclimatization. BAP × KIN interactions significantly improved shoot multiplication and elongation. Media with 15 or 30 g L⁻¹ sorbitol yielded the highest multiplication (5.75 ± 0.19 and 6.39 ± 0.21 shoots per explant). The highest root numbers occurred on QL medium with 0.6–1.2 mg L⁻¹ IBA. After 30 days of acclimatization, 1.2 mg L⁻¹ IBA plants had the shortest roots yet the greatest mean root number (8.35 ± 0.41). Continuous IBA use supported a robust root system, critical for successful acclimatization. Kodad et al. (2021) conducted an *in vitro* study to promote shoot formation from nodal explants of local almond ecotypes (“Beldi”) from eastern Morocco. Explants were cultured on MS or Heller media supplemented with auxin (IBA) and cytokinins (BAP, TDZ, KIN) at different concentrations. TDZ was superior to other regulators; 1 mg L⁻¹ TDZ produced the highest shoot proliferation (63.6 ± 0.63%). For genotype S1 on MS, the mean number of regenerated shoots reached 13 ± 0.54. In rooting, the highest rooting (60.41 ± 0.81%) and roots per shoot (7.3 ± 1.36) were obtained for genotype S2 on half-strength MS with 1 mg L⁻¹ IBA. Approximately 80% of plantlets acclimatized successfully without morphological abnormalities. Borkheyli et al. (2021) optimized micropropagation of the widely used clonal rootstock GF-677 by testing medium type, plant growth regulators and carbohydrate sources. Proliferation was carried out on MS, WPM and DKW media with 0–2.0 mg L⁻¹ BA. Rooting employed the same media with 0–2.0 mg L⁻¹ IBA. A separate experiment compared carbohydrate sources. The highest shoot number and fresh shoot weight occurred on MS with 1.0–2.0 mg L⁻¹ BA. Rooted shoot percentages were greatest on MS or WPM with 1.0–2.0 mg L⁻¹ IBA; maximum roots per plantlet were recorded on WPM with 1.0 mg L⁻¹ IBA. Sorbitol enhanced shoot proliferation relative to sucrose; average root number and length were highest

with sorbitol and sucrose media, respectively. Post-transfer survival during acclimatization reached 67%. Koaym et al. (2022) assessed growth regulator effects on shoot multiplication and rooting in four cultivars (Shami Furk, Dafadii, Ferragnes, Fournat). The aim was to identify combinations maximizing shoot number/length and rooting percentage/roots per plant/root length. Optimal sterilization (highest survival, no contamination) was achieved with 0.5% NaOCl for 10 min plus 0.1% HgCl₂ for 30 s in Dafadii (75%) and in Shami Furk and Fournat (62.5%). In Ferragnes, 0.1% HgCl₂ for 1 min gave the best response (50%). For multiplication, MS with 1.0 mg L⁻¹ BA + 0.1 mg L⁻¹ IBA + 0.2 mg L⁻¹ GA₃ performed best for Shami Furk (5.31 shoots/explant; 6.23 cm) and Dafadii (3.67 shoots/explant; 4.98 cm). Ferragnes responded best to MS with 1.0 mg L⁻¹ BA + 0.2 mg L⁻¹ GA₃ (3.84 shoots/explant; 4.67 cm), whereas Fournat showed no meaningful improvement. For rooting, 1.0 mg L⁻¹ IBA yielded the highest rooting in Shami Furk (75%), Dafadii (40%) and Ferragnes (35%). Acclimatization success reached 85% in Shami Furk and 50% in Ferragnes. Haghi et al. (2023) noted that seedling (seed-derived) rootstocks are common in fruit production but cause non-uniformity. They tested IBA at 0, 1500, 2500 and 3500 mg L⁻¹ ex vivo for rooting of cuttings of the promising peach × almond hybrid rootstock TF92 (Karaj, 2019; heated beds). IBA significantly affected rooting percentage, root number, root dry weight and rooting rate; the highest rooting (78.45%) occurred at 2500 mg L⁻¹, recommended for TF92 cuttings. *In vitro*, the highest percentage of rooted plantlets was obtained on MS with 1 mg L⁻¹ IBA, which the authors recommend for TF92 *in vitro* rooting. Dungarwal and Sangeeta (2023) reviewed factors influencing *in vitro* micropropagation of fruit trees: explant characteristics, sterilization, phenolic exudation control, medium composition, carbon sources/additives, environmental conditions (light, temperature), plant growth regulators, pH and acclimatization substrates. Using very small explants (~0.5 mm, e.g., shoot tips) is effective for virus-free cultures. The most successful sterilization employed 10–30% sodium hypochlorite with two drops of Tween-20 for 15–20 min. Explants include shoot tips, axillary buds, single-node segments, leaf discs, flower buds and seeds. Pre-soaking explants in an antioxidant solution (150 mg L⁻¹ citric acid + 100 mg L⁻¹ ascorbic acid) for 2–24 h minimized phenolic exudation. Setting medium pH to 5.7 improved development and rooting. Optimal growth occurred at 25–28 °C under a 16 h light/8 h dark photoperiod. Sucrose remains the most common carbon/energy source. Full-strength basal salts generally support better growth and multiplication; however, for species with high phenolic exudation (e.g., date palm, mango, apple), liquid media are advantageous at initiation and rooting. Low concentrations of auxins, cytokinins and gibberellins are typically sufficient; BAP and 2iP are common cytokinins, while NAA and IBA are relatively less stable in rooting media. Auxin/cytokinin combinations are generally more effective than gibberellins for multiplication. A 1:1:1 (v/v) mixture of vermiculite:sand:peat is recommended for acclimatization. Razavi and Aghbolaghi (2023) optimized micropropagation across 11 *Prunus dulcis* genotypes (Mamaei, Shekoufeh, Fragnies, and breeding lines A1, A2, A3, A4, A5, A7, A8, A9), focusing on optimal explant type and sterilization. Responses varied with genotype. For example, in A1, herbaceous shoots yielded a lower multiplication rate (30.12%) than woody shoots (40.20%), whereas in A7 the reverse was true (herbaceous 40.13% vs woody 36.20%). Overall, woody shoots performed better in A1, A3, A8, A9, SH, M and F. Sterilization efficacy was also genotype-dependent: 25% NaOCl for 15 min was superior for A7, A8, A9 and F, while 50% NaOCl for 10 min was preferable for other genotypes. Genotype × sterilization × explant-type interactions significantly influenced multiplication capacity, growth and rate. Hammud et al. (2024) aimed to establish protocols for ‘Ferragnes’ and ‘Ferraduel’. MS media with BAP at 1.0 or 2.0 mg L⁻¹ were tested. In ‘Ferragnes’, 1.0 mg L⁻¹ BAP was more suitable, increasing leaf number, whereas 2.0 mg L⁻¹ promoted shoot elongation. Explants initiated growth by day 5 under both BAP levels, and ~73% reached subculture size by week 3. IBA concentrations did not significantly affect rooting percentages; however, 0.1 mg L⁻¹ NAA improved rooting. Rooting success

reached 23.07% (mean 2.6 roots) in ‘Ferragnes’ and 62.50% (mean 2 roots) in ‘Ferraduel’. Ahmadi et al. (2024) developed micropropagation protocols for *Amygdalus scoparia* L. and *A. lycioides* Spach (Rosaceae). Nodal explants were cultured on MS with factorial combinations of BA (0, 0.25, 0.5, 1, 2, 3 mg L⁻¹) and IBA (0, 0.1, 0.25, 0.5 mg L⁻¹) in a completely randomized design (four replicates). In *A. lycioides*, the highest regeneration occurred with 0.5 mg L⁻¹ BA + 0.25 mg L⁻¹ IBA; in *A. scoparia*, with 2 mg L⁻¹ BA + 0 mg L⁻¹ IBA. Shoot number followed similar trends, underscoring species-specific hormonal requirements. Gök (2024) evaluated *in vitro* multiplication and rooting performance of 62 almond genotypes selected from Nevşehir, Niğde and Mersin-Mut, and developed an effective sterilization protocol, reducing contamination to 0.73%. Significant differences among genotypes were observed for micropropagation performance, and several previously unreported observations were documented. Eliwa et al. (2025) examined the effects of IBA (0.0, 0.5, 1.0, 2.0, 3.0, 4.0 mg L⁻¹) on *in vitro* rooting and acclimatization in the peach rootstocks ‘Okinawa’, ‘Nemared’ and ‘Garnem’. ‘Garnem’ achieved the highest rooting rate, roots per plant and root length overall. At 2.0 mg L⁻¹ IBA, rooting reached 100% (Garnem), 83.33% (Okinawa) and 75% (Nemared). ‘Garnem’ produced the most roots per plant (12.33) at 4.0 mg L⁻¹ IBA, whereas maxima in ‘Nemared’ and ‘Okinawa’ were 8.00 and 5.00 at 3.0 mg L⁻¹ IBA. Root lengths varied significantly with IBA; ‘Garnem’ had the longest average roots (5.33 cm), followed by ‘Okinawa’ (2.49 cm) and ‘Nemared’ (1.43 cm). However, 4.0 mg L⁻¹ IBA induced abnormal roots and callus in all three genotypes. Acclimatization survival was 93% (Garnem), 90% (Okinawa) and 75% (Nemared). Gök et al. (2025) assessed eight selected almond genotypes on full-strength and half-strength NRM media with IBA at 0, 1, or 2 mg L⁻¹. The tallest plants were obtained in genotype 48-6 (2.04 cm), and the highest leaf number in 33-B-44 (12.26 leaves). Rooting was observed in genotype 33-B-54 from Mersin-Mut on ½ NRM with 2 mg L⁻¹ IBA. As these materials are products of selection breeding, these are the first reports for these genotypes. Bai et al. (2025) optimized an *in vitro* propagation protocol for seedling production of *A. pedunculata*. The optimal sterilization sequence was 70% ethanol (30 s) followed by 2% NaClO (20 min). Shoot induction occurred on MS with 0.5 mg L⁻¹ 6-BA and 0.1 mg L⁻¹ 2,4-D; proliferation was supported on MS with 0.1 mg L⁻¹ 6-BA and 0.3 mg L⁻¹ IBA. Rooting was induced on ½ MS with 0.3 mg L⁻¹ IBA + 0.1 mg L⁻¹ NAA. Acclimatization was conducted on a peat:perlite:vermiculite mixture (6:3:1, v/v/v), yielding high *ex vitro* survival. This protocol enables large-scale production and supports both industrial utilization and conservation of this economically valuable species.

Micropropagation studies in almond and almond × peach hybrids therefore constitute a rich literature encompassing diverse genotypes, media and applications. An evaluation of the reviewed studies indicates that explant type, medium composition, combinations of plant growth regulators, and culture conditions vary considerably. These factors directly influence shoot proliferation, rooting success, and acclimatization efficiency. Protocols developed for widely used rootstocks such as GF-677, Garnem, HS314, and G×N-9 are particularly noteworthy, as they enhance multiplication capacity and facilitate adaptation to *ex vitro* conditions. Nevertheless, genotypic variation remains a decisive factor in propagation performance, while additional elements—including light regimes, carbohydrate sources, and antioxidant applications—play critical roles in determining the overall success of *in vitro* culture.

CONCLUSIONS

Micropropagation studies on almond and almond × peach hybrid genotypes demonstrate that propagation success is strongly influenced by genotype, culture medium composition, plant growth regulators, and culture conditions. Evidence from the literature highlights the critical roles of cytokinins (BA, TDZ) and auxins (IBA, NAA) during shoot proliferation and rooting, although success rates vary considerably among genotypes. Moreover, light regimes, carbohydrate sources, antioxidant applications, and sterilization protocols are also decisive factors shaping overall culture performance.

The limited rooting observed in certain genotypes underscores the necessity of genotype-specific optimization. By comprehensively evaluating micropropagation research on almond and its hybrids, this review provides a valuable reference for both researchers and practitioners. Future studies should prioritize the development of standardized, genotype-responsive, and highly efficient protocols. Such advances will be essential for improving commercial propagation systems, producing disease-free plant material, and conserving rare genotypes. Ultimately, this review contributes to the more effective planning of future micropropagation research in almond.

ABSTRACT

Global climate change imposes increasing and multifaceted pressures on soil health and fertility. Rising temperatures, irregular precipitation patterns, and the accumulation of greenhouse gases in the atmosphere significantly affect the physical, chemical, and biological properties of soils. Elevated temperatures accelerate the decomposition of soil organic matter, reduce soil organic carbon, and increase the risk of salinization and erosion. Intense and erratic rainfall events disrupt soil aggregate stability, lower cation exchange capacity, and enhance nutrient leaching. Conversely, reduced rainfall and drought limit soil moisture availability and nutrient uptake, while suppressing biological nitrogen fixation. Although increased atmospheric CO₂ levels may stimulate microbial activity and nutrient cycling, they can also lead to net carbon losses from the soil. This review explores the complex effects of climate change on soil health, focusing on structural degradation, shifts in pH, salinization, nutrient cycling disruptions, and microbial imbalance. Furthermore, the study discusses mitigation and adaptation strategies (such as conservation agriculture, organic matter management, and integrated nutrient management) that can help reduce climate-related soil degradation. Implementing climate-resilient soil management practices is essential to sustain long-term soil health and agricultural productivity.

Keywords: Climate change, Greenhouse gases, Carbon cycle, Sustainable agriculture

INTRODUCTION

Soils underpin terrestrial life and global food systems by regulating water and nutrient cycles, storing vast amounts of carbon, and hosting extraordinarily diverse biota that drive decomposition and fertility. Soils contain more carbon than the atmosphere and terrestrial vegetation combined, positioning them as a critical yet vulnerable component of both the climate system and agricultural productivity. Recent studies and guidance from agricultural and climate agencies emphasize that the size and persistence of this soil carbon pool confer both opportunity and risk: management can enhance sequestration, but warming and land-use pressures can accelerate losses (Keller and Handler 2024). Anthropogenic climate change, which has resulted in approximately 1.1 °C of global warming relative to the 1850–1900 baseline, has already led to widespread and multifaceted impacts on both natural and managed ecosystems. There is high confidence that continued warming will exacerbate risks to soil health and food security. The IPCC's Sixth Assessment Synthesis Report (2023) highlights that

increasing temperatures, shifting precipitation regimes, and more frequent extremes are altering hydrologic and biogeochemical processes that determine soil health, with cascading effects on crop yields and rural livelihoods.

Warming directly influences the soil carbon balance by accelerating microbial metabolism and decomposition, potentially shifting soils from net sinks to net sources of CO₂ in sensitive regions. Recent whole soil warming experiments and model data analyses published since 2023 highlight the significant vulnerability of soil organic carbon, including deeper soil layers that were previously considered relatively stable. These studies consistently report increased carbon emissions under sustained warming and underscore considerable uncertainty in both the magnitude and timing of these losses (Ren et al. 2024). Hydroclimatic change compounds these thermal effects. Intensifying heavy-precipitation events increase erosion, destabilize aggregates, and enhance nutrient leaching, while prolonged drought reduces soil moisture, suppresses biological nitrogen fixation, and impairs microbial functioning. Emerging assessments and regional projections show rising erosion risk under warmer, more variable climates, with implications for water quality and long-term soil fertility (Yin et al. 2025; Lua et al. 2024; IPCC 2023). At the farm and landscape scales, these physical and biogeochemical stresses translate into measurable risks for crop production. A 2023 article in *Nature Reviews Earth & Environment* notes that warmer temperatures, elevated CO₂, and altered water availability jointly modulate cereal yields, often exposing heat and water-stress thresholds that management must address. Complementary experimental evidence suggests that climate change and intensified cropland use can reduce soil multifunctionality, defined as the concurrent provision of nutrient cycling, carbon storage, and water regulation. This reduction in multifunctionality may, in turn, constrain agronomic resilience (Sünnemann et al. 2023)

Given soils' centrality to both mitigation (through carbon storage) and adaptation (through water retention, nutrient buffering, and biological resilience), safeguarding soil health is a prerequisite for maintaining agricultural productivity under climate change. This review synthesizes current understanding of how warming, altered precipitation, and rising atmospheric CO₂ interact to affect soil physical structure, chemistry (pH, salinity, cation exchange capacity), and biology (microbial communities and nutrient cycling). It also evaluates evidence based strategies such as conservation agriculture, organic matter management, and integrated nutrient management, which have the potential to slow or reverse climate related soil degradation while maintaining agricultural productivity.

CLIMATE CHANGE DRIVERS AFFECTING SOIL HEALTH

Rising temperatures

Global warming has led to significant increases in both air and soil temperatures, with profound implications for ecosystem processes and climate feedbacks. In China, analyses of five decades of temperature records (1962–2011) revealed that surface soil temperatures rose 31% more than air temperatures and that warming penetrated as deep as 3.2 meters, amplifying soil respiration rates by up to 28% and extending the growing season by approximately 20 days (Zhang et al. 2016). Similar long-term trends have been documented in other regions, such as North Rhine-Westphalia, Germany, where soil warming ranged from 0.36 °C to 0.47 °C per decade depending on depth (Dorau et al. 2022). Moreover, projections for the coming decades

imply continued soil warming, especially in deeper layers, potentially altering global temperature regimes and cascading into ecological disruptions (Bradford 2019; Lembrechts 2022). Taken together, these findings highlight the increasingly urgent need to incorporate soil temperature dynamics, alongside atmospheric warming, into climate models and ecosystem assessments, as soil warming acts both as a driver and an amplifier of climate change.

Altered precipitation regimes

Global warming is profoundly altering precipitation regimes worldwide, intensifying both the wet and dry extremes and restructuring seasonal patterns. Rising global temperatures increase the atmosphere's capacity to hold moisture, by approximately 2 to 3 percent per degree Celsius on a global scale, with extreme precipitation events intensifying at an even faster rate. This results in more severe rainfall events and prolonged dry periods, even as average precipitation shows an overall increasing trend (Douvile, 2021). Climate models reveal that precipitation becomes less frequent yet more intense in the tropics, with heavy precipitation events increasing by up to 35 % per 1°C warming, despite an overall decline in light rainfall (Guo *et al* 2022). Furthermore, the annual range of precipitation widens significantly; maximum precipitation increases by roughly 3.6 % °C⁻¹, while minimum precipitation rises by only 0.2 % °C⁻¹ (Guo *et al.* 2012). Changes in wet and dry season patterns are also evident: across the tropics, many regions are transitioning from annual to biannual precipitation regimes, with wet seasons shortening by an average of about 7 days and beginning 6 days later, while dry seasons grow both longer and drier (Guo *et al.* 2012). Moreover, projections suggest that large precipitation accumulations, which have been rare in historical records, will become exponentially more likely under continued warming, with some events projected to increase by several hundred to over one thousand percent (Neelin *et al.* 2017). Collectively, these alterations not only pose escalating risks for flooding, drought, and agricultural disruption but also challenge water-resource management and infrastructure resilience in both regional and global contexts.

Drought

Anthropogenic global warming is exacerbating drought globally through a combination of elevated atmospheric evaporative demand (AED), altered precipitation dynamics, and soil moisture depletion. Recent high-resolution global drought data (1901–2022) demonstrate that increased AED (driven by rising temperatures) has amplified drought severity by an average of 40 %, and has helped expand drought-affected land by approximately 74 % in the period 2018–2022 compared to 1981–2017, with nearly 30 % of the terrestrial surface experiencing moderate to extreme drought in 2022 alone, 42 % of which is attributable to AED (Gebrechorkos *et al.* 2025). This pattern is echoed regionally; in the Iberian Peninsula, intensified evaporative demand has led to more frequent and severe hydrological droughts, significantly reducing streamflow in both natural and regulated river basins (Lorenzo, 2014). Projections indicate that under moderate emissions scenarios (SSP2-4.5), by mid-century nearly 70 % of global land could face declining soil moisture, increasing agricultural drought risk particularly in regions like India, China, Europe, and the United States (OECD, 2025). Moreover, observational and modeling evidence indicates that drought durations, particularly the longest annual dry spells, may lengthen by the end of the century, substantially exceeding midrange estimates when

models are calibrated with observational data. This convergence of rising temperatures, increased evaporation, and declining moisture storage highlights the urgent need for resilient water resource management to address more frequent, prolonged, and severe drought conditions.

Elevated atmospheric CO₂ (eCO₂)

Elevated atmospheric carbon dioxide, a central driver of anthropogenic climate change, exerts a fundamental influence on plant physiology, hydrology, and ecosystem carbon cycling. However, the magnitude and consistency of these effects remain highly dependent on environmental context. The dramatic rise in CO₂ from preindustrial ~280 ppm to over 427 ppm by 2024 underscores its critical role in enhancing the greenhouse effect and global warming (NOAA, 2024). On the positive side, eCO₂ enhances photosynthetic carbon uptake, thereby increasing terrestrial gross primary productivity (GPP) and improving leaf-level water-use efficiency by reducing stomatal conductance and transpiration (Lucas et al. 2019). Free Air Carbon Dioxide Enrichment (FACE) studies report biomass increases of approximately 20 to 30 percent, although these gains are often limited by soil nutrient availability, particularly nitrogen and phosphorus. These nutrient constraints account for a substantial portion of the variability observed in carbon fertilization responses (Fu et al. 2024). Additionally, elevated CO₂ can partially buffer plants against drought and heat stress by improving water status and mitigating oxidative damage, as seen in meta-analyses across diverse species and controlled experiments such as those involving *Arabidopsis* (Wang et al. 2022). That said, eCO₂ can also yield counterintuitive outcomes: enhanced leaf area may increase canopy transpiration, and changes in plant hydraulics (e.g., altered stomatal behavior or hydraulic conductance) may reduce drought resilience in certain contexts (Becklin et al. 2017). Moreover, the CO₂ fertilization effect may be waning globally due to nutrient constraints and ecosystem saturation, potentially weakening the land carbon sink and increasing reliance on mitigation strategies. Thus, although elevated carbon dioxide plays a critical role in modulating plant responses under climate change, its overall influence is determined by species-specific traits, environmental interactions, and resource availability. This underscores the need for nuanced, multifactor assessments in ecosystem modeling.

SOIL PROPERTY ALTERATIONS UNDER CLIMATE STRESS

The climate stress factors mentioned above reconfigure soils' physical, chemical, and biological properties in ways that directly govern fertility and yield stability.

Physical properties: structure, aggregation, and erosion susceptibility

Under climate stressors such as intensified precipitation, prolonged droughts, and fluctuating temperatures, soil physical properties undergo marked degradation. Elevated temperatures and extreme heat events can reduce cohesion among clay particles, shifting textures toward more silt-sized fractions and compromising structural integrity through induced cracking and dehydration of 2:1 clay minerals (Mangi et al. 2017). Drought exacerbates these effects by suppressing the production of root mucilage and microbial exudates that normally stabilize aggregates, leading to a decline in mean weight diameter (MWD) and aggregate

stability; the removal of vegetation during drought further accelerates macroaggregate breakdown and diminishes aggregate-associated organic carbon (Reinsch et al. 2024). When heavy rainfall follows such weakened soil states, erosion susceptibility increases markedly: less aggregated soils, particularly coarser-textured ones, show higher erodibility and decreased stability across successive rainfall events, with significant reductions in soil K-factor observed (Yao 2019). Moreover, intensifying land use changes under warming climates influence aggregation through altered thermal amplitudes and moisture regimes, which in turn affect porosity, bulk density, and infiltration potential (Li et al. 2023). Collectively, these climate-induced disruptions in soil structure, aggregation, and susceptibility to erosion threaten soil health, water retention, and ecosystem resilience.

Chemical properties: pH, salinity, cation exchange capacity (CEC), and nutrient leaching

Under climate stressors such as shifting precipitation patterns, rising temperatures, and sea level rise, soil chemical properties are significantly disrupted. Soil pH is highly sensitive to climate-driven changes in temperature, precipitation, and biogeochemical cycling. Increased precipitation and extreme rainfall events accelerate the leaching of base cations (Ca^{2+} , Mg^{2+} , K^+ , Na^+), which normally buffer acidity, leading to progressive soil acidification (Yaseen 2024). At the same time, enhanced mineral weathering and the oxidation of soil organic matter under warming release hydrogen ions (H^+) and mobilize aluminum (Al^{3+}), further lowering pH and impairing nutrient availability (Brinkman, 1990). In drought-prone regions, reduced leaching and the accumulation of soluble salts can, conversely, raise soil pH (alkalinization), particularly in calcareous soils where carbonates become concentrated in the profile (Bui, 2017). Moreover, rising atmospheric CO_2 and associated shifts in soil respiration influence carbonic acid equilibria, which can modify pH dynamics seasonally. Overall, climate stress exerts a bidirectional influence: acidification dominates in humid and high-rainfall systems, while alkalinization often occurs in arid and semi-arid landscapes both with profound consequences for nutrient cycling, microbial activity, and long-term soil fertility.

In coastal and semi-arid zones, sea-level rise and saltwater intrusion have increased soil salinity by between 1 % and 33 % over recent decades, while elevated evapotranspiration in arid regions inhibits salt leaching, promoting accumulation in the root zone (Rahman et al. 2018). Climate-induced warming accelerates the decomposition of soil organic matter (SOM), which critically underpins soil Cation Exchange Capacity (CEC) a determinant of the soil's ability to retain key nutrient cations. As SOM declines, especially in coarse-textured or low-clay soils, CEC diminishes, reducing nutrient retention and amplifying leaching losses when intense precipitation occurs (Mandal and Sathyaseelan, 2012). Together, these shifts diminish nutrient retention, elevate the risk of nutrient leaching, and impair soil fertility and ecosystem function under ongoing and future climate stress.

Biological properties: microbial diversity, processes, and symbioses

Climate-induced stressors such as warming, drought, and altered precipitation patterns have pronounced effects on soil microbial diversity, functional processes, and symbiotic relationships. Meta-analyses reveal that on average, global warming reduces soil bacterial and fungal diversity by approximately 16% and 20%, respectively, with projected declines reaching

56% (bacteria) and 81% (fungi) under high-emission scenarios by mid-century trends that threaten soil organic carbon (SOC) sequestration and ecosystem resilience (Sun et al. 2025). Long-term experimental observations in grasslands indicate that warming restructures microbial successional trajectories, making fungal communities increasingly divergent over time and emphasizing deterministic environmental filtering over stochastic assembly (Guo et al. 2018). Drought compounds these effects: prolonged moisture deficits and elevated temperatures significantly alter the composition of bacterial and fungal communities, reduce their richness, and disrupt established symbioses, including mycorrhizal colonization patterns (Seaton et al. 2012). At the functional level, changes in temperature and precipitation influence the complexity of microbial networks. In temperate steppes, warming has been shown to increase fungal network complexity and stability, particularly during cooler seasons, indicating a shift toward more interconnected, fungi-driven processing networks (Yu et al. 2024). Moreover, symbiotic relationships are altered: drought promotes arbuscular mycorrhizal fungi (AMF) colonization and structural adaptations like increased hyphal networks and vesicle formation, enhancing plant drought tolerance and nutrient uptake via osmolyte production and water relations adjustments (Silva et al. 2025). Collectively, climate stress reduces microbial diversity, reshapes community assembly, alters biogeochemical functioning, and reshapes symbiotic partnerships, with profound implications for nutrient cycling, plant resilience, and ecosystem stability.

CONSEQUENCES FOR AGRICULTURAL PRODUCTIVITY

Climate-induced soil degradation exerts cascading effects on agricultural systems, ultimately eroding crop yields, resource efficiency, and resilience.

Declines in Crop Yields and Soil Multifunctionality

Climate driven soil degradation, reflected in declines in soil organic carbon, increased erosion, loss of structural integrity, and reduced microbial function, significantly undermines both crop yields and soil multifunctionality. Intense warming and drought drive accelerated SOC decomposition and erosion, reducing moisture retention, nutrient availability, and key ecosystem services that support plant growth (e.g., carbon and nutrient cycling) (Cheng et al. 2017). Empirical modeling shows that warming reduces global yields of maize by 3.4%, wheat by 2.4%, rice by 0.3%, and soybean by 5%, while improving SOC can dramatically mitigate these losses bringing yield reductions down to near-neutral levels in many cases (Deng et al. 2023). Furthermore, precipitation reduction in semi-arid grasslands disrupts microbial biodiversity and network complexity, resulting in diminished soil multifunctionality such as nutrient provisioning, microbial growth efficiency, and organic matter decomposition (Wang et al. 2023). Conservation agriculture, which enhances soil health through practices like reduced tillage and increased SOC and microbial biomass, has been shown to sustain or even boost crop yields (e.g., 9.3% wheat yield increase) under long-term warming, highlighting how degraded soils may lose resilience in the absence of such practices (Teng et al. 2024). Together, these findings illustrate a clear mechanistic pathway: climate-induced soil degradation erodes the suite of soil functions that underpin crop productivity and ecosystem resilience, unless countered by proactive soil management strategies.

Nutrient Inefficiencies and Increased Fertilizer Demand

Climate driven soil degradation, including the loss of organic matter, erosion, altered moisture regimes, and disruption of nutrient cycling, exacerbates nutrient inefficiencies in agroecosystems and consequently increases fertilizer demand. Declining soil organic matter (SOM) and fertility force farmers to rely more heavily on synthetic fertilizers, yet as SOM diminishes, soils' physical and biological ability to retain nutrients also deteriorates, causing a substantial portion of applied nutrients to be lost to leaching or volatilization (Mosier et al. 2021). For example, degraded dryland agroecosystems often exhibit both nutrient depletion and reduced fertilizer-use efficiency, prompting escalating fertilizer applications that further increase greenhouse gas emissions (Iqbal et al. 2023). Furthermore, rising temperatures above critical thresholds (e.g., 28 °C) have been empirically linked to sharp increases in fertilizer use particularly nitrogen in irrigated regions, as farmers attempt to offset heat- and moisture-induced yield declines, even as nutrient uptake efficiency falls (Quan et al. 2024). Together, these dynamics reveal a vicious cycle: climate stress degrades soil, impairs nutrient retention, and forces greater fertilizer inputs, often with diminishing returns and increased environmental and economic costs.

Water Stress and Drought Vulnerabilities

Climate-driven soil degradation such as erosion, loss of organic matter, structural decline, and vegetation removal, significantly heightens water stress and drought vulnerability in agroecosystems. The degradation of soil structure and aggregation due to intensified erosion and compaction diminishes infiltration rates and reduces soil water-holding capacity, leading to faster runoff and reduced water availability during dry periods (Radulov and Berbecea, 2023). Degraded soils lacking organic matter retain less moisture and are more prone to moisture deficits under warming and erratic precipitation, which amplifies drought impacts on plant growth and ecosystem resilience (IUCN, 2024). Land-use changes such as deforestation and the conversion of forests and rangelands to bare or cultivated land further impair the land's capability to buffer drought by disrupting vegetation cover and hydrological buffering (Liu et al. 2025). Empirical evidence from drought studies also shows that soil drying reduces microbial function and alters soil carbon and nitrogen processes, degrading the soil habitat and making ecosystems less resistant to prolonged water deficits (De Silva, 2025). Together, these processes create a feedback loop whereby degraded soils lose both physical and biological resilience, leaving landscapes more susceptible to water stress and prolonged drought under changing climate conditions.

Enhanced Greenhouse Gas Emissions and Feedbacks

Climate-induced soil degradation through warming, drying, erosion, and land-use change leads to an increase in greenhouse gas emissions from soils, thus reinforcing a positive feedback loop that accelerates climate warming. Experimental warming studies demonstrate that a ~1.5 °C rise in temperature significantly elevates soil CO₂ emissions (~13%), nitrous oxide (N₂O) emissions (~35%), and methane (CH₄) emissions (~23–38%) in various ecosystems, collectively adding 1.8 gigatonnes CO₂-equivalent per year and undermining the mitigation potential of terrestrial carbon sinks (Liu et al. 2020). Decomposition of previously stable soil organic carbon including deep SOM and permafrost carbon is accelerated by microbial activity

under warming conditions, potentially releasing hundreds of petagrams of carbon over time and substantially reducing overall SOC storage (Cheng et al. 2017). Soil erosion and topsoil loss also enhance CO₂ emissions: an experimental study found that removal of the top 20 cm of soil increased seasonal CO₂ efflux from cropland, whereas adding soil reduced emissions, indicating that degradation itself can amplify GHG flux (Liang, 2018). In peat-rich ecosystems, draining and degradation of peatlands commonly undertaken for agriculture, transforms these systems from net carbon sinks into potent sources of CO₂ (and additionally CH₄ upon rewetting), making them a major driver of GHG emissions (Leifeld and Menichetti, 2018). Together, these processes illustrate that soil degradation triggers heightened emissions of CO₂, N₂O, and CH₄, creating self-reinforcing feedbacks jeopardizing both soil carbon stocks and broader climate stability.

Table 1. Climate Change Impacts on Agricultural Productivity

Process	Impact Mechanism	Productivity Consequence
Yield reduction	Stress from heat, drought, and fragmentation of multifunctionality	Lower output and food security risks
Nutrient losses	Leaching, runoff, low CEC	Reduced fertilizer efficiency, increased inputs
Water stress	Poor infiltration, structure loss, reduced water retention	Greater drought sensitivity, yield instability
Greenhouse feedbacks	SOC loss and N ₂ O emissions	Climate feedback loop and inefficiency

MITIGATION AND ADAPTATION STRATEGIES

Soil resilience to climate change depends on integrated, site-specific combinations of practices that protect soil structure, rebuild organic matter, improve nutrient and water use efficiency, and enhance biological function. Below we synthesize the evidence for key strategies and note important caveats.

Conservation agriculture (reduced/no-till, residue retention, cover crops)

Conservation agriculture (CA), anchored by the principles of reduced or no-tillage, residue retention, and diversified cropping (including cover crops), serves as a pivotal approach for both climate change mitigation and adaptation in agroecosystems. Reduced soil disturbance preserves structure and surface organic matter, enhancing water infiltration, reducing erosion, and promoting soil carbon accumulation (Zomer, 2017). Residue retention and cover cropping further bolster these benefits by maintaining soil moisture, regulating temperature extremes, and incrementally increasing soil organic carbon (SOC), soil aggregation, and nutrient cycling (Page, 2020). Meta-analyses reveal that CA often enhances yields modestly with cumulative

gains in maize of ~4 % while improving drought resilience and yield stability under variable rainfall (Corbeels et al. 2020). Significantly, CA practices substantially reduce nitrous oxide (N₂O) emissions by about 7 % with no-till alone, and up to 30 % when combined with residue retention and rotation and increase crop yield by over 9 %, offering synergistic mitigation and productivity gains (Zhu et al. 2025). In drought settings, implementing cover crops and residue retention has shown striking results for example, soybean yields up to 29 % higher, along with improved water-use and photosynthetic performance (Whippo, 2024). Altogether, conservation agriculture offers a multifaceted strategy: it mitigates greenhouse gas emissions, enhances soil health and resilience, and stabilizes crop productivity under climate stress though site-specific outcomes may vary.

Organic matter management: composts, manures, green manures, and biochar

Organic matter management, including the application of composts, manures, green manures, and biochar, is increasingly recognized as an effective strategy for mitigating and adapting to climate change impacts on agricultural productivity. The incorporation of composts and animal manures improves soil fertility by supplying essential macro- and micronutrients, enhancing cation exchange capacity (CEC), and stimulating beneficial microbial activity, which together bolster plant growth and resilience under climate stress (Goldan et al. 2023). Green manures, particularly legumes, contribute biological nitrogen fixation and enhance soil organic carbon (SOC) stocks, thereby improving soil aggregation, water-holding capacity, and nutrient cycling, which are critical under conditions of drought and variable rainfall (Mandal et al., 2004). Biochar, due to its stability and high carbon content, provides long-term carbon sequestration potential while also enhancing soil structure, nutrient retention, and water-use efficiency, and has been shown to reduce nitrous oxide (N₂O) and methane (CH₄) emissions from soils (Lehmann et al., 2011). Empirical studies demonstrate that co-application of biochar with organic manures or compost further improves soil physicochemical properties, crop productivity, and microbial community dynamics, highlighting the synergistic potential of integrated organic matter management strategies (Wang et al. 2019). Collectively, these practices not only enhance soil health and crop yields but also provide critical climate mitigation benefits by sequestering carbon and reducing greenhouse gas emissions, positioning them as vital tools for sustainable agriculture in a warming world.

Integrated nutrient management (INM) and precision fertilization

Integrated Nutrient Management (INM), which combines organic sources (e.g., manures, composts, crop residues) with judicious use of inorganic fertilizers, enhances soil fertility, synchronizes nutrient release with crop demand, and improves nitrogen use efficiency thereby reducing greenhouse gas emissions and enhancing resilience under climate variability. Long-term field studies in rice–wheat systems demonstrate that INM significantly boosts soil organic carbon (SOC), aggregate stability, and soil health compared to sole inorganic treatments, while supporting sustained crop productivity (Paramesh et al. 2023). Empirical trials in dryland maize production reveal that INM using crop residue plus fertilizer substantially increases SOC (by up to ~52%) and enhances water retention, thereby bolstering drought resilience and productivity (Wang et al. 2023). Precision fertilization through spatial diagnostics, remote sensing, and targeted nutrient placement further refines INM by aligning

application timing and dosage with site-specific crop needs, minimizing nutrient losses (e.g., nitrate leaching, N₂O emissions), and enhancing fertilizer use efficiency (Bayu, 2020). Overall, the integrated application of INM and precision fertilisation offers a robust pathway for climate-smart agriculture, achieving dual goals of improved productivity and reduced environmental impact under changing climatic conditions.

Water management: mulching, micro-irrigation, and landscape retention

Effective water management strategies encompassing mulching, micro-irrigation, and landscape-level retention, play a critical role in enhancing agricultural resilience amid climate change. Mulching, whether organic (e.g., straw, gravel) or synthetic (e.g., plastic film), significantly reduces soil evaporation, moderates soil temperature, enhances moisture retention, suppresses weeds, and improves soil structure and fertility, thereby reducing irrigation demand and promoting water-use efficiency under arid and semi-arid conditions (El-Beltagi et al. 2022). Micro-irrigation systems, such as drip or trickle irrigation, deliver water precisely to the root zone, minimizing losses via evaporation or runoff; they enhance water-use efficiency, support deeper root development, and can be integrated with fertigation for optimized nutrient delivery (Bwire et al. 2024). The synergy between mulching and micro-irrigation yields even greater benefits: combining mulching with drip systems can reduce water consumption by as much as 40–50%, decrease irrigation needs by 30%, and substantially boost crop yield and water productivity in vegetable production. At the landscape or catchment scale, soil mulching and micro-irrigation can lower the blue water footprint, delivering water savings of millions of cubic meters per year in some basins (Nouri et al. 2019). Furthermore, strategic landscape water retention such as enhancing soil organic carbon can markedly buffer yield losses under drought, as demonstrated in modeling studies showing that a 1% increase in soil organic carbon reduced potato yield loss from 16.4% to 7% during a severe drought (Heinz et al. 2025). Collectively, these practices form an integrated adaptation and mitigation framework, reducing vulnerability to shifting precipitation and water stress, stabilizing crop outputs, and enhancing efficiency and sustainability of agricultural systems in a warming climate.

Agroforestry, diversification, and perennial integration

Agroforestry, diversification, and perennial integration constitute complementary mitigation–adaptation strategies that increase the resilience and sustainability of agricultural landscapes by strengthening ecological function, buffering climatic shocks, and enhancing long-term productivity. Agroforestry by integrating trees and shrubs with crops and/or livestock modulates microclimate, reduces erosion and surface runoff, improves water and nutrient retention, and stores carbon in woody biomass and soil, thereby delivering both adaptation and mitigation co-benefits at field and landscape scales (Ghanbari et al. 2025). Crop and system diversification (spatial, temporal and genetic diversification, intercropping and mixed farming) reduces yield and income volatility, spreads climate and pest/disease risk across species and time, and improves soil health and biological pest regulation, making farm livelihoods less sensitive to extreme weather and market shocks (Mihrete and Mihretu, 2025). Integrating perennial species whether as tree crops, forages, silvopasture, or newly domesticated perennial grains reduces the need for annual tillage, increases below-ground carbon allocation through deeper, longer-lived root systems, curbs nutrient leaching and erosion, and can improve drought

resilience through more extensive water capture and use (Chapman et al. 2022). When combined in diversified, perennial-rich agroecosystems (for example agroforestry mosaics, perennial–annual polycultures, and mixed silvopasture), these approaches produce synergistic outcomes higher and more stable ecosystem services (carbon sequestration, water regulation, soil conservation), improved on-farm biodiversity, and reduced vulnerability of production systems to climate variability while also opening policy and market pathways for scaling adoption.

Biological and engineered soil amendments (microbial inoculants, engineered bio-products)

Biological and engineered soil amendments including microbial inoculants and cutting-edge bioengineered products offer promising pathways to bolster agricultural resilience amid climate change. Microbial inoculants, or plant growth–promoting microorganisms (PGPMs), improve soil health by enhancing nutrient cycling, increasing plant resilience to drought and salinity, and reducing reliance on synthetic fertilizers and pesticides a source of considerable greenhouse gas emissions (Díaz-Rodríguez et al. 2025). These inoculants help restore soil microbial communities degraded by intensive agriculture, enriching ecosystem functions crucial for climate mitigation and sustainable productivity (Campos-Avelar et al 2023). Furthermore, targeted applications of PGPMs in wheat under drought stress have demonstrated significant improvements in plant drought tolerance, biomass, and soil enzymatic activity highlighting their practical effectiveness under abiotic stress (Li et al. 2023). In parallel, engineered bio-products such as biochar produced via pyrolysis of organic biomass provide multifunctional benefits: sequestering carbon over centuries, enhancing soil water-holding capacity and nutrient retention, increasing microbial activity, and reducing emissions of nitrous oxide and methane (Shyam et al. 2025). Emerging biochar–microbe synergistic systems have shown spectacular results; for example, in calcareous soils, combining biochar with auxin-producing microbial inoculants (and L-tryptophan) improved canola yield by over 200%, while amplifying nutrient uptake and soil microbial activity (Mustafa et al. 2025). These methodologies underscore a powerful suite of mitigation and adaptation strategies: they enhance soil function, improve plant stress tolerance, and help sequester carbon all critical in transitioning toward climate-smart agriculture.

Policy, incentives, and carbon programs

Policy frameworks, targeted incentives, and carbon programs form a crucial triad for catalyzing climate-resilient agricultural transformations. Effective policy instruments ranging from subsidies, taxes, rural finance, land tenure reforms, extension services, to certification schemes, can significantly enhance the adoption of climate-smart agricultural (CSA) practices among smallholder and large-scale farmers, by reducing financial risk and aligning actions with public goods objectives (Van Asseldonk et al. 2023). Carbon programs, including credits for soil carbon sequestration or regenerative practices, offer a direct financial reward mechanism for climate-positive farming. Yet program design matters greatly: recent reporting highlights that in the U.S., while programs like the USDA’s EQIP and related climate-smart initiatives channel billions in incentives, over half the funding may not effectively reduce greenhouse gas emissions; implementation gaps likewise limit program efficacy (The Guardian, 2024).

Similarly, corporate-led carbon credit initiatives, such as those by Indigo Ag, have supported farmers transitioning to regenerative agriculture by paying premiums for verified carbon credits, yet critics warn that delays in payments and inequitable cost-sharing can undermine farmer engagement (Reuters, 2024). Internationally, the European Union's Common Agricultural Policy (CAP) and eco-schemes offer adaptation and mitigation support via agri-environmental commitments and climate-related rural development funds, although recent critiques argue that policy alignment with climate goals remains inconsistent due to imprecise metrics and diluted incentives (European Commission, 2025). Collectively, these insights underscore that a blend of well-calibrated policies, robust incentive structures, and transparently governed carbon programs is essential for driving agricultural systems toward sustainability, resilience, and equitable climate mitigation.

FUTURE DIRECTIONS AND RESEARCH GAPS

Safeguarding soil health under climate change requires closing several scientific and implementation gaps. Below I synthesize the most important open questions highlighted in recent literature, then propose concrete research priorities to guide the next decade of work. Key thematic gaps are

1. Measurement, monitoring, reporting and verification (MRV) for soil carbon and other soil health indicators;
2. Mechanistic understanding of carbon stabilization and losses across depths and land-uses;
3. The soil microbiome as an actionable lever for resilience;
4. Scalable, location-specific practice packages and socio-economic pathways to adoption; and
5. Modelling and remote sensing tools for up-to-date, trustworthy decision support.

RECOMMENDATIONS

Safeguarding soil health in the era of climate change requires integrated approaches that bridge scientific research, land management, and socio-economic policy. Healthy soils underpin climate mitigation and adaptation by sequestering carbon, regulating water, and supporting biodiversity, yet they remain vulnerable to degradation from unsustainable practices, land-use change, and governance gaps. Embedding soil health explicitly into climate policies at national and international levels is therefore essential to meet long-term environmental and food security goals, as exemplified by initiatives such as the European Union's Green Deal.

At the same time, economic incentives play a pivotal role in aligning farmer and landowner decision-making with environmental objectives. Payment for ecosystem services, subsidies for agroecological practices, and programs that reward carbon sequestration can make sustainable land stewardship financially viable. Secure land tenure and robust governance frameworks further underpin these efforts, empowering communities to prioritize long-term soil health investments over short-term exploitation.

Moving forward, several priorities emerge for policymakers and practitioners. Developing standardized soil health indicators encompassing physical, chemical, and biological dimensions, will enable consistent monitoring and adaptive management across regions.

Greater investment in research and farmer education is equally vital, fostering innovation and knowledge transfer that accelerate the adoption of resilient practices. Moreover, the promotion of sustainable agricultural systems, including crop rotation, cover cropping, reduced tillage, and organic farming, offers proven pathways to strengthen soil functions and buffer climate extremes. Finally, broad-based public awareness and inclusive stakeholder engagement are critical to ensure that soil health remains a shared societal priority.

In sum, advancing soil health requires more than agronomic interventions; it demands coherent policies, supportive institutions, and active engagement across scales. By aligning science, practice, and governance, soil can be secured as both a natural capital asset and a cornerstone of climate resilience in the decades ahead.

CONCLUSION

Soil health is a cornerstone of sustainable development and climate resilience. Effective policies that integrate soil conservation into broader environmental and economic frameworks are essential for safeguarding this vital resource. By implementing the recommendations outlined above, governments can foster an environment where soil health is prioritized, leading to enhanced agricultural productivity, environmental sustainability, and climate change mitigation.

ABSTRACT

Viburnum opulus L. (Gilaburu) is a traditional medicinal plant known for its antioxidant, anti-inflammatory and diuretic properties. It is rich in polyphenols, vitamin C, L-malic acid and other bioactive compounds that contribute to its potential as a natural protectant. In this study, the effects of Gilaburu (Glb) extract on oxidative stress-induced cytotoxicity in human endothelial cells were investigated. Treatment with Glb extract alone resulted in a significant, dose-dependent reduction in cell viability. Exposure to hydrogen peroxide (H₂O₂) caused marked cytotoxicity, simulating oxidative damage. However, pretreatment with a Glb extract of 100 µg/mL significantly improved cell viability compared to H₂O₂ alone, indicating a protective effect. These results suggest that Glb can attenuate oxidative stress and maintain endothelial cell integrity. Its traditional use in kidney and liver diseases, hypertension and menstrual cramps may be related to its antioxidant effects. Overall, *V. opulus* extract proves to be a promising natural cytoprotectant against oxidative damage in vascular cells.

Keywords: Cytotoxicity, Gilaburu, Hydrogen peroxide, Protective effect, *Viburnum opulus*

INTRODUCTION

Viburnum opulus L. is known in Turkey as “Gilaburu” and in Europe as “Guelder rose” (Cam M, Hisil Y, Kescu A, 2007). *V. opulus* L. (VO) is a plant of the Viburnaceae family, formerly also used for Caprifoliaceae. Gilaburu (Glb) is a shrubby, perennial, fast-growing, white-flowered plant that can grow up to 2-4 meters long, sheds its leaves in winter, can live up to 300 years thanks to its ground shoots and starts to harvest 2-3 years after planting (Özer 2000, Çam 2005, Hızlısoy 2009).

Glb is used to treat kidney stones, liver, stomach, prostate and urinary bladder diseases, diabetes, mumps, rheumatism, hemorrhoids, nervous disorders, high blood pressure and menstrual disorders (Aksoy et al., 2004, Çam 2005). The Glb fruit contains vitamin K, viburnin, isovaleric acid, salicin, salinic acid, (+)-catechin, (+)-epicatechin, quercetin, resin and valeric acid, which gives the plant a unique odor. In addition to its use in the food industry, the Glb fruit, which contains a lot of vitamin C and antioxidant substances, is also used in the paint and printing ink industry (Kalyoncu et al., 2007).

Glb shows a strong protective (cytoprotective) effect against oxidative stress at the cellular level thanks to its rich phenolic compounds, flavonoids, anthocyanins and proanthocyanidins. Numerous studies have shown that Glb extract supports the antioxidant defense system by reducing cell damage caused by free radicals. In particular, a study on pancreatic MIN6 beta cells found that Glb fruit phenols increase cell viability against hydrogen

peroxide (H_2O_2)-induced oxidative stress, reduce the production of ROS (reactive oxygen species) and maintain mitochondrial membrane potential (Turkcan et al., 2020). In addition, in the acid-induced colitis model, Glb fruit suppresses oxidative tissue damage as well as inflammation in intestinal tissue; it was found to protect tissue integrity by increasing antioxidant enzyme levels (Koyuncu et al., 2020). These results show that the cell-protective effect of Glb extract is largely dependent on strengthening the antioxidant system and maintaining oxidative balance.

The aim of this study was to investigate the potential cytoprotective effects of Glb against oxidative stress-induced cytotoxicity in HUVEC cells. Specifically, the dose- and time-dependent effects of Glb extract on cell viability were to be investigated both alone and in the presence of H_2O_2 , a known trigger of oxidative damage. The results contribute to the understanding of *V. opulus* as a potential natural antioxidant and cytoprotective agent for use in oxidative stress associated with vascular disease.

MATERIAL AND METHOD

This study used human umbilical vein endothelial cells (HUVECs) obtained commercially from the American Type Culture Collection (ATCC). HUVEC cells were cultured in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% fetal bovine serum (FBS), 1% penicillin/streptomycin (100 IU/mL and 100 μ g/mL, respectively), and 2 mM L-glutamine. The HUVEC cells were maintained at 37 °C in a humidified atmosphere with 5 % CO_2 . For cell viability experiments, cells were seeded in 96-well plates at a density of 2×10^4 cells/well and allowed to adhere overnight before treatment.

Cell viability was determined using the WST-1 assay (Biovision, Germany). For this purpose, HUVEC cells were treated with Glb at concentrations of 1, 10, 50, 100 and 200 μ g/mL for 24 and 48 hours to determine dose- and time-dependent effects. To induce oxidative stress, cells were treated with H_2O_2 at concentrations of 50, 100 and 200 μ M. To evaluate the protective effect, cells were pretreated with Glb (50, 100 and 200 μ g/mL) for 24 and 48 hours and then exposed to 100 μ M H_2O_2 for 24 or 48 hours. After the treatments, 10 μ L of WST-1 reagents were added to each well and incubated for 1 hour. The absorbance was measured at 450 nm using a microplate reader. Cell viability was calculated as a percentage compared to untreated control cells.

All experiments were performed in triplicate and data were expressed as mean $\pm$ standard deviation (SD). Statistical analyses were performed using GraphPad Prism software (version 10). A one-way analysis of variance (ANOVA) was performed to determine significant differences between groups, followed by a Tukey post hoc test for multiple comparisons. A p-value of less than 0.05 was considered statistically significant.

RESULTS AND DISCUSSION

The effects of Glb and H_2O_2 on endothelial cell viability were evaluated by WST-1 analysis (Figure 1). Glb treatment resulted in a significant, concentration- and time-dependent decrease in human endothelial cell viability. At both 24 and 48 hours, cell viability was reduced in all Glb-treated groups compared to control, with statistical significance at each concentration (Figure 1A, $p < 0.0001$). Exposure to 50 $\mu\text{g/mL}$ and higher concentrations resulted in a significant decrease in viability, with 200 $\mu\text{g/mL}$ reducing cell viability by more than 50% after 48 hours (Figure 1A). These results indicate that the Glb extract exerts cytotoxic effects on endothelial cells at higher concentrations and longer exposure times. This dose-dependent cytotoxicity may be attributed to the presence of bioactive compounds in the extract that exert prooxidant or membrane disrupting effects at higher concentrations, which is consistent with previous findings on plant-derived polyphenolic compounds (Wang et al., 2018; Galati and O'Brien, 2004). Furthermore, H_2O_2 exposure resulted in a progressive decrease in cell viability, with the most dramatic effect occurring at 200 μM , especially after 48 hours (Figure 1B). The cytotoxic profile of H_2O_2 served as a model for oxidative stress against which potential protective effects of Glb could be compared in subsequent experiments. These results provide a basis for evaluating the antioxidant or protective role of Glb against H_2O_2 -induced oxidative damage in endothelial cells.

Figure 1. Effects of Glb and H_2O_2 on the viability of HUVEC cells. Cells were treated with increasing concentrations of (A) Glb (1–200 $\mu\text{g/mL}$) and (B) H_2O_2 (50–200 μM) for 24 and 48 hours. Statistical significance compared to control: **** $p < 0.0001$.

To evaluate the protective effect of Glb against oxidative stress, endothelial cells were pretreated with different concentrations of Glb before being exposed to 100 μM H_2O_2 (Figure 2). As expected, H_2O_2 alone caused a significant reduction in cell viability after both 24 and 48 hours. However, pretreatment with Glb significantly attenuated this cytotoxic effect. The 100 $\mu\text{g/mL}$ Glb group showed the highest recovery of viability after 24 hours, indicating an optimal concentration for the protective effect (Figure 2). This protective effect is likely due to the

antioxidant components in Glb extract, such as flavonoids, phenolic acids or other redox-active molecules known to scavenge reactive oxygen species (ROS) or enhance endogenous antioxidant defense mechanisms (Rahman et al., 2021; Heim et al., 2002). Although the 200 $\mu\text{g}/\text{mL}$ dose also provided partial protection, its effect was less pronounced, possibly due to intrinsic cytotoxicity at higher concentrations. These results demonstrate the potential antioxidant and cytoprotective properties of Glb against oxidative damage in endothelial cells. The observed decrease in protection at 200 $\mu\text{g}/\text{mL}$ may reflect a biphasic (hormetic) dose-response curve in which antioxidant effects dominate at lower doses, while cytotoxic effects occur at higher concentrations, a phenomenon observed with other phytochemicals such as quercetin and resveratrol (Calabrese et al., 2010). The current results highlight the therapeutic potential of Glb as a cytoprotective agent against oxidative stress, provided that its concentration is carefully optimized. Future mechanistic studies are warranted to elucidate the specific molecular pathways through which Glb exerts these effects, including its influence on intracellular ROS levels, expression of antioxidant enzymes (e.g. SOD, catalase, GPx) and apoptotic signaling cascades.

Figure 2. Protective Effect of Glb against H_2O_2 -induced cytotoxicity in HUVEC cells. Cells were pre-treated with Glb at concentrations of 50, 100, and 200 $\mu\text{g}/\text{mL}$ for 24 and 48 hours, followed by exposure to 100 μM H_2O_2 for 24 or 48 hours. Statistical significance: **** $p < 0.0001$ vs. control.

CONCLUSIONS

In summary, Glb shows promising cytoprotective properties, possibly due to its content of bioactive phytochemicals. However, the cytotoxic effects observed at high concentrations underline the importance of dose optimization for future therapeutic application. Further studies are required to elucidate the underlying molecular mechanisms and to assess the *in vivo* relevance of these results

A PRELIMINARY ANALYSIS OF FUNCTIONAL TRAIT COMPOSITION IN ADRIATIC SEA FISHERIES

Elvis KAMBERI, Edmond HALA

Department of Aquaculture and Fisheries, Agricultural University of Tirana, Albania

**Corresponding author e-mail: ekamberi@ubt.edu.al*

ABSTRACT

Natural and anthropogenic drivers have both impacted marine ecosystems over the years, altering ecosystem structure and functionality. These external drivers can affect multiple levels of biological organizations, disrupting species interactions, recruitment dynamics and trophic structure, potentially leading to cascading effects throughout the ecosystem. In this context, trait-based approaches are becoming more widely acknowledged as useful instruments enhancing current ecosystem-based fisheries management. In this study, we investigated the temporal dynamics in the functional traits in the Adriatic fisheries landings over 5 decades (1970-2020). A landings dataset comprising 27 taxonomic groups was transformed into 18 functional trait categories related behaviour, ecology, distribution and biology. Dirichlet regression was applied to all trait categories in order to investigate the dynamics of individual traits. Over the last five decades, the community's trait composition has undergone notable transformations. Traits such as zoobenthivore, stenobathic, and winter spawning have become more prominent, whereas features like short lifespan, piscivore, and summer spawning have steadily diminished. Meanwhile, other characteristics including thermal tolerance and distribution range have remained largely stable, reflecting resilience to broader ecological shifts. Expanding the application of trait-based analyses may offer valuable insights for refining fisheries management strategies and safeguarding ecosystem functionality in the face of ongoing change.

Keywords: functional traits, fisheries landings, Adriatic Sea

INTRODUCTION

Marine ecosystems have been impacted by both natural variability and human activities, leading to alterations in ecosystem structure and functioning (Pech et al., 2017; O'Hara et al., 2021). Through the continuous interplay of these external drivers, ecosystems have faced multiple consequences, often described in terms of changes in fish population abundance and species turnover (Barausse et al., 2011; Fortibuoni et al., 2017). Instead, the ecological significance of these processes lies in the resulting functional changes they induce, which ultimately determine ecosystem functioning (Beisner et al., 2003; Mouillot et al., 2013). Ecosystem integrity, therefore, depends not only on species abundances, but also on the traits and ecological roles of these species within the community. (Hooper et al., 2005).

In the Adriatic Sea, fishing pressure and warming have caused significant alterations in community composition. These include declines in large, long-lived piscivores and an increasing dominance of smaller, short-lived species that occupy lower trophic levels (Barausse et al., 2011; Sguotti et al., 2022). These processes have further facilitated the northward expansion of thermophilic species (Azzurro et al., 2019), consistent with broader trends observed across the Mediterranean basin (Fortibuoni et al., 2017). Such trait alterations, as observed in the Adriatic Sea, have important implications for fundamental ecosystem processes,

including functional redundancy and energy flow through food webs, which in turn influence ecosystem productivity and vulnerability to disturbances (Hooper et al., 2005; Palkovacs et al., 2012; Biggs et al., 2020). Given the strong influence of external drivers on ecosystem dynamics and functioning, trait-based approaches are increasingly recognized as valuable tools for strengthening ecosystem-based fisheries management (Barnett et al., 2019). By addressing the current limitations, they offer a pathway toward more effective and adaptive strategies to safeguard marine resources under changing environmental conditions (Costa et al., 2024)

In this study, we investigated five decades of Adriatic fisheries landings to examine temporal trends in trait modalities across biological, distributional, ecological, and behavioural categories, providing new insights into ecosystem responses to external drivers.

MATERIALS AND METHODS

Data

Fisheries landings in the Adriatic Sea were analyzed over 1970–2020 using Food and Agriculture Organization (FAO) data. Based on the requirements of the Data Collection Framework (DCF) and national reporting practices, these landings data are reported either at species level or at higher taxonomic levels (e.g., genus or family). To ensure data consistency during the whole study period, analyses were restricted to taxa with continuous records across the study period. Specifically, species with gaps exceeding 15 consecutive years were excluded from the analyses. In total, 27 groups were retained, including 11 at species level, 7 at the genus level, 5 at the family level and 4 taxa including species from more than one family. For groups aggregated above the species level, the dominant contributor to total landings was taken as representative.

Using available information from existing literature, an additional dataset was constructed including information regarding various categories of functional traits such as; biology, distribution, ecology and behaviour. Each trait category included up to five distinct modalities, resulting in a total of 61 trait modalities. Each species was assigned to only one modality per trait category, based on attributes characteristic of the adult stage. To quantify temporal changes in the functional structure of the fish community, the Community Weighted Mean (CWM) was calculated for each trait modality using the following equation:

$$CWM = \sum_{i=1}^S p_i x_i$$

where p_i represents the relative abundance of species i in a given year and x_i is a binary value indicating the presence (1) or absence (0) of a given trait modality for that species.

We calculated relative abundance by comparing each species' yearly catch to the total catch of all species in that year. This way, the influence of each species on trait expression reflects how important it was in the community. The method was applied to all 61 trait categories, giving yearly values of community traits from 1970 to 2020.

Statistical analyses

To investigate the dynamics of individual functional traits, we applied Dirichlet regression, which is particularly suitable for modelling continuous proportional data and reduces common violations of statistical assumptions often encountered in ecological analyses (Douma and Weedon, 2019). Models were fitted in R with the DirichletReg package, incorporating a smoothed effect of year as the predictor of trait modality proportions.

RESULTS AND DISCUSSION

To investigate temporal variation in trait modalities across functional categories, we applied Dirichlet regression, which revealed distinct patterns over the past five decades. Traits such as zooplankton feeding, stenobathic species, and winter spawners increased in prevalence, whereas short-lived species, piscivores, and summer spawners declined. Meanwhile, some modalities, including stenothermal, eurythermal, and globally distributed species, remained largely unchanged. Among the four categories, biological and ecological traits displayed the most contrasting dynamics, while distribution and behavioural traits showed stability in their dominant modalities.

Across the study period, community biological traits showed contrasting dynamics in relation to longevity, body size, and body form. Species with intermediate lifespans (10–19 years) increased significantly from the mid-2000s, becoming dominant, whereas those with 5–9 years longevity declined after peaking during the same period. Short-lived (<5 years) and long-lived (≥ 20 years) species remained consistently low and stable (Figure 1, left). Body size composition was characterized by the persistent dominance of the 20–50 cm group, while very large (>100 cm), large (50–100 cm), and small (<20 cm) species consistently represented a minor fraction, showing little temporal variation and suggesting structural stability in size distribution (Figure 1, middle). Similarly, body form composition remained largely unchanged, with atractoid species predominating throughout the whole time series and flat, rounded, and deep-bodied forms contributing only marginally (Figure 1, right).

Figure 1. Temporal dynamics of biological trait categories, with fitted trajectories estimated using Dirichlet regression.

Community distribution traits displayed clear and persistent trends, without major shifts or reversals (Figure 2). Optimal temperature preferences were dominated by species associated with 15–20 °C, which remained stable, while both cooler (<15 °C) and warmer-affinity (20–25 °C, 25–30 °C) species contributed minimally. Depth composition was dominated by 50–200 m species, which increased slightly after the 1990s following an abrupt decline; >200 m species rose modestly until the early 1990s and then returned to initial levels, whereas 0–50 m taxa remained rare and stable. Habitat type was consistently dominated by pelagic species, which increased steadily since the 1990s, while benthic and benthopelagic species stayed in low levels. Distribution ranges were largely dominated by temperate species, with global and subtropical species contributing only marginally and showing little variation. Seabed morphology reflected an increasing dominance of water-column species alongside a decline in soft-bottom taxa and minor contributions from variable-substrate species. Spawning habitat was characterized by the persistent dominance of pelagic spawners, which increased steadily, whereas benthic spawners declined slightly and remained low in prevalence.

Figure 2. Temporal dynamics of distribution trait categories, with fitted trajectories estimated using Dirichlet regression.

Ecological traits exhibited more diverse patterns, with both stability and shifts across modalities (Figure 3). Diet remained dominated by zooplanktivores throughout the time series, with their contribution increasing further from the early 1990s, while piscivores declined. Trophic level was consistently dominated by level 3 species, which became even more prevalent over time, whereas level 4 species declined. Salinity range was likewise dominated by euryhaline species, which increased further from the early 1990s, while stenohaline taxa decreased. Temperature range showed a stable dominance of eurythermal species, with stenothermal species remaining at low levels. Depth range and spawning period were characterized by shifts in dominance between modalities: stenobathic species increased markedly from the early 2000s, overtaking eurybathic species, and winter spawners increased from the late 2000s while summer spawners declined; autumn, spring, and year-round spawners remained at consistently low levels.

By comparison, behavioural traits showed remarkable stability, with no major changes in the dominant modalities (Figure 4). The assemblage was consistently characterized by grazing species with high mobility that formed schools, while active predators, ambushers, solitary species, and taxa with lower mobility remained comparatively minor components.

Figure 3. Temporal dynamics of ecological trait categories, with fitted trajectories estimated using Dirichlet regression.

Figure 4. Temporal dynamics of behaviour trait categories, with fitted trajectories estimated using Dirichlet regression.

CONCLUSIONS

Overall, the analysis indicates that while some traits have shifted markedly in response to external pressures, others have remained stable, revealing both vulnerability and persistence within the Adriatic fish community. The growing dominance of smaller, short-lived, thermophilic species aligns with broader regional trends, whereas the stability of distributional and behavioural traits points to a degree of functional continuity despite shifts in species composition (Fortibuoni et al., 2017; Sguotti et al., 2022). Collectively, these findings highlight the value of trait-based approaches for uncovering ecosystem responses and supporting ecosystem-based fisheries management strategies.

ABSTRACT

The integration of organic fertilizers into horticultural systems has gained increasing importance as a sustainable strategy to enhance soil fertility and crop productivity under challenging soil conditions. This study aimed to evaluate the effects of various organic fertilizers including manures from small ruminants, cattle, poultry, and vermicompost on the chemical properties of a sandy-calcareous soil and the growth performance of melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.). The study focused on how recommended fertilizer doses influence soil chemical quality and plant growth. The results indicated that organic fertilization altered soil electrical conductivity (EC) and available phosphorus (P) levels. Poultry and cattle manures led to notable improvements in soil nutrient content. Additionally, plant growth parameters such as stem diameter and fruit weight were positively affected by organic fertilizers, particularly poultry manure. Crop-specific responses were observed: melon plots exhibited higher soil EC and available P, while watermelon plants showed superior performance in stem diameter, fruit flesh thickness, and soluble solid content. In contrast, melon plants recorded higher chlorophyll levels. Overall, poultry manure emerged as the most effective input for enhancing plant growth, while vermicompost and cattle manure also contributed depending on the crop type. These results suggest that organic fertilizers, especially poultry manure, are valuable tools for improving soil fertility and crop productivity in calcareous soils.

Keywords: Calcareous soils, Fruit quality, Mediterranean climate, Organic amendments

INTRODUCTION

Sustainable agricultural systems are an emerging model that promotes the integrated use of organic materials as alternatives to chemical inputs are being developed to ensure more environmentally friendly and efficient food production. In this context, organic fertilizers that enhance soil fertility have come to the forefront. The core component of organic fertilizers, organic matter, serves as a primary source of energy and nutrients for soil-dwelling microorganisms. However, in Turkey and many other agricultural countries, inadequately matured animal manures characterized by high C/N ratios and the presence of root rot pathogens or weed seeds have long been used in crop production. These manures often fail to provide the expected agronomic benefits for both soil and plants (Karaman 2012).

In recent years, there has been a growing demand particularly in intensively cultivated horticultural and greenhouse production areas for thermally treated or fermented organic fertilizers. This trend reflects efforts to promote sustainable agriculture and to optimize the combined use of organic and chemical fertilizers. Nevertheless, these processed fertilizers are significantly more expensive than traditionally matured manures, due to additional processing, packaging, registration, and storage costs. Furthermore, their claimed benefits for practical use often rely more on manufacturer assertions than on robust scientific evidence. Therefore, it is essential to evaluate their effects on soil fertility and plant growth in order to better understand their potential contribution to sustainable agricultural systems and to promote their effective and economical use.

Melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.), among the most widely produced and consumed vegetables globally and in Turkey, are annual crops adapted to warm and temperate climates. While both crops are cultivated in open fields and greenhouses, only about 3% of melon and 2% of watermelon production is conducted under protected cultivation (Anonymous 2001; Taşkaya and Keskin 2004). These crops are valued not only for their edible parts but also for their seeds and rinds, which are utilized across the food, pharmaceutical, and cosmetic industries, making them strategic export commodities. Deep, well-drained, sandy-loam or loamy-sand soils with high water-holding capacity are ideal for watermelon cultivation, while poorly drained soils with shallow groundwater levels (below 1 meter) are unsuitable (Tuna and Özer 2005). Like many other cultivated plants, melons and watermelons respond positively to organic fertilization. Accordingly, the application of solid and/or organic fertilizers in the cultivation of these crops is considered important for improving both yield and quality, as well as enhancing soil health (Bayram et al. 2020).

In this study, the effects of processed organic fertilizers including sheep, cattle, and poultry manures, as well as vermicompost on the chemical properties of calcareous sandy soils and on plant growth in melon and watermelon cultivation were investigated. Additionally, the study aimed to assess how the optimum application rates recommended by organic fertilizer manufacturers for plant growth influence soil fertility. By comparing the effects of these commonly used organic fertilizers on both soil chemical parameters and plant growth indicators, this study identified the strengths and weaknesses of each fertilizer type. The findings offer valuable insights into the practical use of organic fertilizers in sustainable farming systems.

MATERIAL AND METHODS

Site Description

This study was conducted as a field trial at the Finike campus of Akdeniz University (36°18'31"N, 30°08'48"E; altitude: 40 m). According to meteorological data collected during the trial period, the site had an average daily temperature of 19.3 °C, an average daily sunshine duration of 9.10 hours, an average daily open surface evaporation of 125.58 mm, an average daily rainfall of 1.4 mm, an average daily wind speed of 1.6 m/sec, and an average relative humidity of 66.03%.

Soil samples collected to represent the trial area were analyzed prior to the experiment. The soil was classified as sandy loam in texture. It had a neutral pH and was classified as non-

saline. The soil also contained a high level of lime and was rated as sufficient in terms of humus content. Total nitrogen (N) and available phosphorus (P) levels were determined to be adequate, while the cation exchange capacity (CEC) was classified as low.

Organic Fertilizers and Fertilization Practices

In this trial, various heat-treated organic fertilizers (processed at 65–70 °C) were applied, including small ruminant manure (goat and sheep manure; T1), cattle manure (T5), poultry manure (T4), and vermicompost (T2) (Table 1). Additionally, control (T3) plots were established, which received only chemical fertilizers (detailed below) without any organic fertilizer input. The application rates of the organic fertilizers were determined based on the manufacturers' recommendations and supported by findings from previous studies (Maltaş 2023; Maltaş et al. 2024). This approach aims to develop practical organic fertilization strategies suitable for field conditions, specifically for melon and watermelon cultivation, while improving soil chemical properties and supporting plant growth.

Table 1. Some properties of organic fertilizers used in the experiment

Parameter	Organic fertilizer			
	Vermicompost	Chicken manure	Cow manure	Goat-sheep manure
Organic matter, %	45	62	35	70
EC (dS/m)	6.0	2.6	11.2	7.5
Organic C, %	26.1	35.96	20.3	40.6
Humic/fulvic acid, %	41.5	36	15	28
Total N, %	3.0	2.2	1	1.5
Total P, %	1.5	1.76	1.5	1.5
Total K, %	1.0	1.62	-	2
Humidity max., %	20	20	20	20
pH	6-8	6.2	7-9	8-10
C/N	9/1	16/1	20/1	27/1
C/P	17/1	20/1	13/1	27/1

The application rates were as follows: 4 Mg ha⁻¹ for vermicompost, 8 Mg ha⁻¹ for cattle manure, 6 Mg ha⁻¹ for goat manure, and 4 Mg ha⁻¹ for poultry manure. In addition to these inputs, chemical fertilizers certified for use in organic farming were applied through a drip irrigation system to support plant nutrition throughout the experimental period. These chemical inputs were selected based on the initial soil analysis and estimates of nutrient removal by the crops (Zengin 2023).

Previous studies have demonstrated that the use of organic mulching materials (such as straw, sawdust, and compost) can improve microclimatic conditions and enhance the effectiveness of organic fertilizers (Gao et al. 2019; Teasdale and Mohler 2000). Mulching has been shown to promote soil biological activity, thereby improving nutrient uptake efficiency by plants and contributing to sustainable farming practices (Li et al. 2019). Therefore, in this study, a mulch was applied to the experimental plots to maximize the effectiveness of organic fertilizers.

Implementation of the Experiment

In this study, melon and watermelon cultivation was carried out using four types of heat-treated organic fertilizers. The experimental setup was established according to a randomized block design with three replications. The organic fertilizers were applied uniformly to the plots based on their respective application rates (in dry weight).

Melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.) seedlings were procured from a commercial nursery. Melon seedlings (Anka F1) were transplanted at a spacing

of 2.0 m between rows and 0.3 m within rows, while watermelon seedlings (Peykan F1) were planted at 2.0 m between rows and 0.6 m within rows. Both crops were cultivated over a vegetation period of approximately 90–100 days.

Throughout the growing period, all essential cultural practices such as weed control, hoeing, and plant protection treatments were carried out. In addition, irrigation and fertigation were performed using a drip irrigation system. The daily irrigation requirements of the plants were calculated based on climatic parameters (including rainfall, temperature, and relative humidity), soil texture and moisture, and plant needs (e.g., signs of wilting). These water requirements were integrated with the optimized fertilization strategy to ensure proper crop management.

Sampling and Analysis

Soil samples were air-dried and sieved through a 2 mm mesh prior to analysis. To characterize the initial soil conditions, samples were collected from the 0–30 cm soil depth using an auger before the experiment began. These samples were analyzed for texture, pH, electrical conductivity (EC), lime content, organic matter, total nitrogen (N), available phosphorus (P), and cation exchange capacity (CEC). Additionally, to evaluate the effects of organic fertilizer applications on soil chemical properties, samples collected at harvest were analyzed again for organic matter, total nitrogen, available phosphorus, and CEC.

The methods used for analyzing the above-mentioned soil parameters were as follows: soil texture was determined using the hydrometer method (Bouyoucos 1955); pH and EC were measured in a 1:2.5 soil-to-water suspension (Jackson 1967; Anonymous 1982); lime content was determined using the calcimeter method (Çağlar 1949); organic matter was measured using the modified Walkley-Black method (Black 1965); total nitrogen was determined using the Kjeldahl method (Kacar 1995); available phosphorus was analyzed according to the Olsen method (Olsen and Sommers 1982); and CEC was determined using the ammonium acetate method (Kacar 1995).

At the end of the experiment, pomological and physiological traits were assessed in plant and fruit samples (Figure 1 and Figure 2). For each treatment replication, measurements and evaluations were performed on three randomly selected plants per plot. The results were expressed as the average of these three plants.

The evaluated pomological characteristics included: stem base diameter (cm; measured with a caliper), fruit fresh weight (g; measured with a precision balance), and yield (kg da⁻¹; calculated). The physiological parameters included: soluble solids content (SSC), fruit juice pH, total chlorophyll content (measured with a chlorophyll meter), and rind thickness (mm; measured with a caliper).

Figure 1. Views of selected physiological and pomological traits in watermelon plants (A: Soluble solids content, B: Chlorophyll content, C: Fruit flesh thickness, D: Stem base diameter, E: Fruit juice pH, F: Fruit weight)

Figure 2. Views of selected physiological and pomological traits in watermelon plants (A, C: Harvested fruits; B: Fruit juice pH)

Statistical Analyses

The numerical data obtained in this study were statistically analyzed using the SPSS 23.0 software package. The significance levels of soil chemical properties and plant pomological and physiological parameters were determined through analysis of variance (ANOVA) at the 5% significance level. Parameters showing statistically significant differences were further evaluated using Duncan's multiple range test for mean separation. In addition, Pearson correlation analysis was performed to determine the relationships among the measured parameters (SPSS 2008).

RESULTS AND DISCUSSION

Soil Chemical Properties

At the end of the growing season, the effects of different organic fertilizer treatments on soil cation exchange capacity (CEC), organic matter (OM) content, total nitrogen (N%), and available phosphorus (P, mg/kg) were evaluated for watermelon cultivation (Table 2). According to the statistical analysis, changes in CEC, total N, OM (%), and available P values in watermelon plots were found to be statistically non-significant.

Table 2. Effects of applications on CEC, OM, total N and available P contents in watermelon soil

Treatments	CEC (meq/100)	% OM	% N	P (mg/kg)
T1	26.54	2.26	0.16	22.17
T2	29.33	2	0.15	19.47
T3	31.04	2.1	0.16	13.36
T4	28.11	2.17	0.18	18.52
T5	30.58	1.92	0.18	38.54
ANOVA (%5)	NS ¹	NS	NS	NS

¹ NS; not significant.

In contrast, in melon cultivation plots, although changes in CEC, total N, and OM (%) were also statistically non-significant, the variation in available phosphorus content was statistically significant at the $P < 0.05$ level (Table 3). Among the treatments, T4 (48.60 mg/kg) resulted in the highest increase in available phosphorus content compared to the other applications.

Table 3. Effects of applications on CEC, OM, total N and available P contents in melon soil

Treatments	CEC (meq/100)	% OM	% N	P (mg/kg)
T1	32.82	2.29	0.15	13.31 b ¹
T2	30.99	2.26	0.16	23.72 ab
T3	30.10	1.85	0.14	9.36 b
T4	29.32	1.97	0.13	48.60 a
T5	29.68	2.00	0.17	40.04 ab
ANOVA (%5)	NS	NS	NS ³	2.966 ** ²

¹ Differences between values not indicated by the same letter are significant at the 5% level. ² **, significant at the 1% level. ³ NS; not significant.

Previous studies have indicated that increasing doses of poultry manure significantly contribute to the enhancement of soil nitrogen content (Okur et al. 2008), while farmyard manure has been found to have a more pronounced effect on available phosphorus levels in soils (Agbenin and Goladi 1997). In the present study, the available phosphorus level in soils under melon cultivation (T4: 48.60 mg/kg) was approximately 20% higher than that in watermelon soils.

Göksu and Kuzucu (2017), in their study investigating the effects of different vermicompost doses on yield and quality parameters in watermelon, reported that vermicompost and chemical fertilizer applications increased the soil ion exchange capacity.

However, in the current study, organic fertilizer treatments did not result in statistically significant changes in CEC for either melon or watermelon soils.

Similarly, Kılıç and Sönmez (2019), in their study on the effects of increasing doses of various organic materials (vermicompost, poultry manure, farmyard manure, leonardite) on soil fertility parameters in lettuce cultivation, found that the effects on soil organic matter content were statistically significant. In contrast, the findings of the current study showed that different organic matter applications had no statistically significant effect on soil organic matter levels in either melon or watermelon cultivation.

Plant Growth Properties

At the end of the cultivation period, among the yield and quality parameters obtained from the watermelon plant, leaf chlorophyll content (SPAD), fruit flesh thickness, fruit juice pH, and soluble solid content were found to be statistically non-significant (Table 4). However, collar diameter was found to be statistically significant at the $P < 0.01$ level, with higher values observed in T1 and T4 (23.41 mm and 23.23 mm, respectively) compared to other treatments. Fruit weight was also found to be statistically significant at the $P < 0.05$ level, with higher fruit weights recorded in T2, T4, and T5 (7.38 kg, 8.13 kg, and 7.52 kg, respectively).

Table 4. Effects of treatments on SPAD, root collar diameter (RCD), fruit weight (FW), fruit flesh thickness (FFT), fruit juice pH (FJpH) and soluble solid content (SSC) in watermelon

Treatments	SPAD	RCA (mm)	FW (kg)	FFT (cm)	FJpH	SSC
T1	37.13	23.41 a ¹	6.99 ab	16.13	5.34	8.38
T2	38.99	17.74 c	7.38 a	15.53	5.60	9.26
T3	34.48	15.95 c	5.50 b	17.55	5.70	8.43
T4	34.71	23.23 a	8.13 a	14.29	5.49	8.70
T5	31.01	20.08 b	7.52 a	10.31	5.46	8.71
ANOVA (%5)	NS ⁴	21.282 *** ³	3.575 ** ²	NS	NS	NS

¹ Differences between values not indicated by the same letter are significant at the 5% level. ² **, significant at the 1% level. ³ ***, significant at the 0.1% level. ⁴ NS; not significant.

Regarding the melon plant, leaf chlorophyll content (SPAD), fruit flesh thickness, fruit juice pH, and soluble solid content were also found to be statistically non-significant (Table 5). However, root collar diameter was found to be statistically significant at the $P < 0.05$ level, with higher values observed in T1, T3, and T4 (14.67 mm, 14.83 mm, and 14.85 mm, respectively). Fruit weight was found to be statistically significant at the $P < 0.01$ level, with the highest fruit weight observed in T1 (2.02 kg).

Üçok et al. (2019), in their study investigating the effects of different organic fertilizer applications on yield, quality, and plant nutrient contents in lettuce (*Lactuca sativa* L. var. *crispa*), reported no significant differences in chlorophyll content among the treatments. Similarly, in our study, although the differences between applications were not statistically significant for both watermelon and melon plants, the chlorophyll value in melon was found to be approximately 20% higher than in watermelon.

Table 5. Effects of treatments on SPAD, root collar diameter (RCD), fruit weight (FW), fruit flesh thickness (FFT), fruit juice pH (FJpH) and soluble solid content (SSC) in melon

Treatments	SPAD	RCA (mm)	FW (kg)	FFT (cm)	FJpH	SSC
T1	42.53	14.67 ab ¹	2.02 a	9.78	5.93	4.80
T2	36.74	13.22 b	1.20 b	9.12	5.79	4.13

T5	40.28	16.15 a	1.45 b	10.97	5.86	3.97
ANOVA (%5)	NS	1.701 **2	5.448 ***3	NS ⁴	NS	NS

¹ Differences between values not indicated by the same letter are significant at the 5% level. ² **, significant at the 1% level. ³ ***, significant at the 0.1% level. ⁴ NS; not significant.

Özen (2018) investigated the effects of different doses of mushroom compost, leonardite, and vermicompost on lettuce yield and quality, and reported that increasing doses of organic material applications resulted in increased collar diameter. In a study conducted on watermelon (*Citrullus lanatus* (Thunb.) Matsum & Nakai), it was reported that different doses of vermicompost (0, 300, and 600 kg/da) did not have statistically significant effects on fruit flesh thickness, fruit juice pH, and soluble solid content (Göksu and Kuzucu 2017). Similarly, in our study, although the differences between treatments were not statistically significant in both watermelon and melon, the collar diameter, fruit flesh thickness, and soluble solid content in watermelon were found to be 40%, 40%, and 100% higher, respectively, compared to melon. In addition, the fruit weight of watermelon was found to be six times higher than that of melon. One of the main reasons for this large difference is the physiologically larger fruit size of watermelon compared to melon.

Correlations Between Soil Properties and Plant Growth

Based on the numerical data obtained from the trial, relationships between soil chemical properties and plant growth parameters were examined. Accordingly, in melon soils, a negative correlation was observed between fruit flesh thickness and organic matter content ($r = -0.539^*$), while a positive correlation was found between root collar diameter and organic matter content ($r = 0.728^{**}$). These correlations suggest that soil organic matter may play a dual role in influencing plant morphological traits. While the positive correlation between root collar diameter and organic matter content implies a supportive role of soil organic matter in promoting vegetative growth and stem development, the negative correlation between fruit flesh thickness and organic matter content might indicate a potential trade-off between vegetative and reproductive growth processes under certain soil conditions. This could be due to nutrient partitioning or changes in water-holding capacity and aeration associated with increased organic matter. However, these relationships are likely to be influenced by plant species, growth stage, and environmental factors.

CONCLUSION

This study aimed to evaluate the effects of various organic fertilizers including manures from small ruminants, cattle, poultry, and vermicompost on the chemical properties of a sandy-calcareous soil and the growth performance of melon (*Cucumis melo* L.) and watermelon (*Citrullus lanatus* Thunb.). The study focused on how recommended fertilizer doses influence soil chemical quality and plant growth. Poultry and cattle manures stood out in improving soil

chemical properties in watermelon cultivation areas, whereas vermicompost and poultry manure significantly enhanced plant growth parameters. For melon cultivation, cattle manure was most effective for soil chemical improvements, while small ruminant, poultry, and cattle manures showed prominent positive effects on plant development. Overall, poultry manure emerged as the most effective input for enhancing plant growth, while vermicompost and cattle manure also contributed depending on the crop type. These results suggest that organic fertilizers, especially poultry manure, are valuable tools for improving soil fertility and crop productivity in calcareous soils. Nonetheless, expanding these findings through comprehensive studies involving different crops, soil types, cultivation locations, and production systems (e.g., greenhouse or organic farming) will be essential to deepen understanding and broaden the applicability of these organic fertilization strategies. These results underscore the critical role of optimized organic fertilization in promoting sustainable agricultural productivity, supporting both soil health and crop performance in Mediterranean agroecosystems.

SMART BIOPOLYMER-BASED PACKAGING SYSTEMS AND CURRENT APPLICATIONS IN FOOD QUALITY TRACEABILITY

Havva Turan, Müge Uyarcan

Manisa Celal Bayar University, Faculty of Engineering and Natural Sciences, Food Engineering Department, Manisa, Turkey

havvaturann35@gmail.com

ABSTRACT

Recently, sustainable packaging technologies have become an important research area in response to the growing demand for food safety and quality monitoring systems. Within this context, smart biopolymer-based packaging systems offer innovative solutions for monitoring quality and safety in food industry due to their eco-friendly structures and superior functional properties. Biopolymers derived from renewable resources (starch, cellulose, etc.) are being integrated with advanced sensor and indicator technologies, to create smart packaging systems. These systems respond to environmental changes and provide real-time information to consumers, thus significantly enhancing food safety and reducing food waste. Smart biopolymer-based packaging systems essentially consist of two basic components: the packaging material and the smart mechanism. Edible sensors and indicators, which provide consumers with information about the food's storage conditions, quality, and packaging environment, are integrated into the packaging as the smart mechanism. Edible sensors detect parameters such as temperature, pH, and freshness in foods and transmit data to control systems, while indicators provide direct visual information about the current state of the food. Such integrations enhance the functionality of packaging and support informed consumer decisions by providing more information. Current studies have focused on developing smart packaging tools such as time-temperature indicators for monitoring freshness and shelf life of frozen foods, gas-sensitive indicators for perishable products like meat and fish, and color-changing films that respond to pH changes. Additionally, advanced technologies such as biosensors, barcodes, and electronic noses monitor chemical and microbiological properties of foods, enabling early detection of potential risks and timely intervention. Smart biopolymer-based packaging offers sustainable and innovative solutions for meeting the quality and safety monitoring requirements of the food industry, thanks to its advantageous properties and superior performance. This study highlights the significance of smart biopolymer-based packaging systems in food quality traceability, current technological applications, consumer expectations, challenges, and future opportunities.

Keywords: Smart biopolymer-based packaging, Food quality, Traceability, Biosensors, Shelf life

INTRODUCTION

The rapid expansion and increasing complexity of the international food supply chain have made it more challenging to maintaining the quality and integrity of food products (Hong et al., 2025). With the increasing public awareness of food safety, consumers have been paying more attention to assessing the quality and safety of food before consumption (Zhao et al., 2023). However, traditional food packaging only provides consumers with information about the composition and expiration date of food, and lacks any monitoring mechanism capable of

detecting microbial spoilage during the shelf life. This highlights the need for more innovative and functional packaging solutions to ensure food safety (Ahmad et al., 2025).

Petroleum-based plastics derived from fossil fuels are widely used in food packaging. Packaging materials such as polyethylene, polyvinyl chloride, and polyethylene terephthalate, are commonly used for packaging products across various sectors. However, compounds like polytetrafluoroethylene, polyvinylidene, epoxy, and acrylic-based lacquers, which impart hydrophobic properties to polymers, are considered unsuitable for food contact, and their use in food packaging is restricted (Niemczyk-Soczynska & Sajkiewicz, 2025; Sabu Mathew et al., 2025). Although traditional packaging materials offer several advantages, their usage is gradually declining, as they pose serious environmental threats and contribute significantly to climate change (Hong et al., 2025; Shafi et al., 2025). As a result, the development of bio-based packaging materials has become increasingly important and a top priority in the packaging industry (Sabu Mathew et al., 2025; Zhao et al., 2023).

Recent studies have focused on developing next-generation smart packaging systems that can detect food quality and freshness throughout the shelf life, contain natural, functional, and antimicrobial bioactive compounds, and are produced from edible sources to contribute to sustainability (Ahmad et al., 2025). Researchers have focused on the use of biopolymer nanocomposite materials in smart food packaging due to their potential to address environmental concerns and ensure food safety. Natural sources, such as animals, plants, and microorganisms, are utilized in the production of these polymer materials (Mishra et al., 2024).

Food packaging materials made from biopolymers extends shelf life by reducing microbiological growth. These materials not only provide protection against water vapor, gas permeation, and moisture but also offer a sustainable solution to address growing environmental concerns due to their biodegradable properties. Furthermore, several researchers have reported that packaging can be further improved by adding various additives to biopolymer films (Chia et al., 2022; Eker et al., 2025; Kanphai et al., 2025; Murugan et al., 2025; Pilehforooshha et al., 2025; Rami et al., 2024).

Biopolymer-based smart packaging systems provide consumers with information about the quality and safety of the product through sensors that monitor internal conditions of the packaging or indicators that detect spoilage, rather than directly monitoring the external sensory attributes of the products (da Silva Ponciano et al., 2025; Sundaresan et al., 2025). Additionally, they contribute to tracking the history of the food from production to consumption (Yılmaz & Yılmaz, 2017). In these systems, the integration of radio frequency identification (RFID), electronic tags, and sensors into food packaging enables more effective monitoring of quality control points, thereby increasing information flow and transparency (Dimou et al., 2024). These packaging systems, which can provide real-time information about the product by detecting microbiological and chemical changes, not only offer physical protection but are also considered innovative technologies in terms of sustainability and food safety, with added functions such as portion control and marketing convenience (Dağbağlı & Kayaardı, 2021; Hepsağ & Varol, 2018). This study addresses food quality traceability, smart biopolymer-based packaging systems, their application in monitoring food quality, current practices, challenges encountered, and future perspectives.

TRACEABILITY IN THE FOOD CHAIN

Traditional packaging systems are designed to protect food against biochemical contamination and to provide consumers with ease of use during storage, handling, and transportation (Siciliano et al., 2024). However, in recent years, this approach has shifted, and packaging has become important not only for protection but also being functional and interactive with consumers. Growing consumer concerns about food safety and freshness, along

with regulatory requirements, have made it necessary for packaging to incorporate advanced systems capable of monitoring the condition of food. Today, the primary goal in food packaging production is to develop innovative solutions that extend the shelf life of food by controlling various biological and physical factors (Li et al., 2025).

Recently, the use of technologies such as coatings, antimicrobial packaging, and modified atmosphere packaging has become widespread in the field of food packaging. However, these packaging methods alone do not provide real-time monitoring of the current condition of food (Mkhari et al., 2025). The traceability of highly perishable foods until they reach consumers is particularly important. Ensuring food safety throughout the supply chain in the food industry is made possible through smart food traceability. The integration of this technology into packaging not only ensures food safety but also helps prevent food waste (Yu et al., 2022). Billions of tons of food are wasted annually due to losses occurring during storage, logistics, transportation, and sales processes within the food supply chain. This not only increases the risk of global food scarcity but also causes serious negative impacts on the environment and human health due to wasted greenhouse gas emissions during the production process (Moustafa et al., 2025). In recent years, new packaging systems have been developed by combining active and intelligent packaging as a novel approach. These innovative technologies enable real-time monitoring of the product and contribute to ensuring food safety and reducing food waste (Huang & Wang, 2025).

Ideal traceability with smart packaging is made possible through the use of indicators, sensors, tags, Internet of Things (IoT), radio frequency identification (RFID), near-field communication (NFC), and other similar technologies that provide information about the condition and quality of the food (Du et al., 2025; Yu et al., 2022). Real-time monitoring can provide information about the product's condition throughout the supply chain, including factors such as temperature, humidity, and microbial spoilage (Du et al., 2025).

In conclusion, smart packaging systems monitor factors such as temperature, humidity, and microbial activity to ensure food traceability throughout the supply chain and optimize quality control processes (Du et al., 2025; Yousefi et al., 2019). Packaging technologies supported by RFID, NFC, and IoT-based systems reduce spoilage risk, prevent product losses, and provide consumers with more reliable information (Kadirvel et al., 2025; Sobhan et al., 2025; Zuo et al., 2022). Moreover, effective shelf life management contributes to reducing food waste and promoting sustainability (Huang & Wang, 2025). In this context, smart packaging emerges as a crucial tool that is not only protective but also enhances traceability and increases transparency within the food chain (Butuc et al., 2025).

SMART BIOPOLYMER-BASED PACKAGING SYSTEMS

Smart biopolymer-based packaging systems are environmentally friendly packages produced from edible and biological sources, such as starch, chitosan, and cellulose. Through integrated indicators or sensors, these systems can monitor critical food parameters in real time, including freshness, temperature, pH, humidity, gas composition, and microbial activity (Huang & Wang, 2025; Mafe et al., 2025). They not only ensure food safety but also combine active and smart components to contribute to sustainability (Amin et al., 2022; Chaudhary et al., 2022). These smart components, integrated into the bio-based polymer matrix, provide consumers with visual feedback—especially through natural color-changing indicators—enabling reliable monitoring of food quality and freshness (Rodrigues et al., 2021).

Biopolymer matrices combined with sensor indicators are commonly used in smart packaging systems. For example, sodium carboxymethyl cellulose stands out as a preferred material for smart packaging due to its transparency, excellent film-forming ability, biodegradability, and high moisture barrier properties (Zhao et al., 2023). These types of bio-

based smart packaging materials can provide consumers with information about the product's condition by reacting to components such as pH, gases, temperature, relative humidity, and enzymes (Huang & Wang, 2025).

In the literature, various smart indicators and biosensors have been developed for detecting pH, temperature, gas concentrations (e.g., O₂, CO₂), humidity, and microbial metabolites (Gam et al., 2025; Huang & Wang, 2025; Panwar et al., 2024; Shao et al., 2021; Yousefi et al., 2019). For example, pH indicators visually reflect chemical changes, such as acidification or alkalization, that occur during food spoilage through color changes, while gas sensors indirectly monitor microbial activity by tracking oxygen or carbon dioxide levels in the packaging atmosphere (Amorim et al., 2022; Gupta et al., 2024; Heo & Lim, 2024; Saliu & Pergola, 2018). Biosensors, on the other hand, can directly provide consumers with information about the product's condition by detecting the presence of specific pathogens or toxins through enzymatic reactions or antigen-antibody interactions (Inês & Cosme, 2025; Khan et al., 2025; Moran et al., 2016). The chemical and physical stability of these indicators and sensors within the biopolymer matrix, their durability under environmental conditions, and their ability to maintain long-term performance are critical for the reliability of the system (Teixeira et al., 2025; Ye et al., 2025). In conclusion, biopolymer-based smart packaging systems play a crucial role in preventing food waste and enhancing consumer safety by enabling the early detection of spoilage, monitoring freshness, and determining the safe consumption period (Akhila et al., 2024; Huang & Wang, 2025).

USE OF SMART BIOPOLYMER-BASED PACKAGING SYSTEMS IN FOOD QUALITY TRACEABILITY

Smart packaging systems are expected to significantly transform the food sector through enhanced traceability, improved sustainability, and industrial integration. However, in some countries, limited knowledge and lack of education in some countries hinder the widespread industrial adoption of these technologies. When combined with environmentally friendly and biodegradable materials, smart packaging not only helps reduce environmental concerns associated with conventional packaging but also contributes to decrease the carbon footprint (Alizadeh Sani et al., 2024).

Smart biopolymer-based packaging systems are classified into two categories as indicators and biosensors that provide smart functionality to the packaging. Indicators provide consumers with information about the product's condition by reflecting physiological or microbial changes occurring in the food (Shao et al., 2021), whereas biosensors deliver information about the product by converting signals generated from the interaction between embedded bioreceptors and specific analytes into stimulus understandable to consumers through a transducer (Nastasijevic et al., 2025). Figure 1 shows the indicators and sensors used to monitor food quality traceability.

Figure 1. Indicators and sensors used in monitoring food quality traceability

(Bodkhe et al., 2025; Palanisamy et al., 2025)

Indicators

Indicators provide consumers with real-time monitoring of food quality and play a crucial role in detecting the freshness of target foods (such as meat, fish, and dairy), as well as changes occurring in the internal or external environment of the packaging. These systems, which deliver real-time information about product quality throughout the supply chain, stand out as innovative packaging solutions with a communication function. The working principle of indicators is based on the color change of dye molecules that are sensitive to environmental factors such as pH, gases (particularly volatile amines and CO₂), and humidity released during food spoilage (Panwar et al., 2024; Shao et al., 2021). These dyes are typically integrated into biodegradable polymer carriers to provide consumers with visual and real-time notifications about the freshness of the product (Yu et al., 2023). Indicators used in smart packaging systems are classified as freshness, time–temperature, pH, ripeness, and spoilage indicators (Kadirvel et al., 2025; Kang et al., 2024). Packaging systems that are sensitive to pH and gases can inform consumers about the level of food spoilage by responding to gases, such as ammonia and ethanol, released during deterioration, through visible color changes. Temperature-sensitive packaging materials reflect temperature fluctuations, facilitating the monitoring of products requiring cold chain transportation. Meanwhile, relative humidity-sensitive systems help maintain product quality by preserving the internal moisture balance within the package. Enzyme-responsive materials convey information about the product’s condition by releasing functional compounds in the presence of specific enzymes (Huang & Wang, 2025).

Freshness indicator

Freshness indicators are systems that detect qualitative or quantitative changes in the concentration of one or more substances (e.g., glucose, volatile nitrogen compounds, biogenic amines, carbon dioxide, or sulfur compounds) within the packaging that correspond to food deterioration (Becerril et al., 2021; Palanisamy et al., 2025). These halochromic indicators can provide consumers with real-time information about the chemical and microbial quality of food (Huang et al., 2025). These systems, which provide information about the freshness of the

product through color changes depending on the packaging environment, are used to monitor factors such as the catalytic activity of endogenous enzymes causing spoilage, microbial growth, temperature, humidity, and oxidation in foods (Zhu et al., 2024).

Smart packaging systems generally use a polymeric or biopolymeric carrier matrix and pH-sensitive dyes that change color by reacting with chemical substances, such as basic nitrogen compounds and organic acids released during food spoilage (Almasi et al., 2022). Common synthetic dyes used in these systems include cresol red, bromocresol purple, and xylene (Li et al., 2025). However, the toxicity and potential carcinogenic risk of these synthetic dyes raise serious health concerns regarding their use in food packaging materials. Therefore, in recent years, studies on the use of natural pigments derived from fruits and vegetables have increased (Almasi et al., 2022). Natural dyes include anthocyanins, alizarin (Ezati et al., 2019; Gam et al., 2025), carotenoids, curcumins (Li et al., 2025), shikonins (W. Sun et al., 2018) and chlorophylls (Hailu et al., 2025a). These natural dyes are considered a more advantageous option than synthetic alternatives for freshness indicators due to their edibility, biodegradability, and low cost (Huang et al., 2025).

Anthocyanins, used as natural indicator dyes in smart packaging, are important pigments that have attracted considerable research interest. Especially during the storage of protein-based foods such as fish and meat, the accumulation of volatile basic nitrogen compounds causes the packaging environment to become alkaline. Under alkaline conditions, anthocyanins change to blue or green, allowing visual monitoring of pH changes; when the pH shifts from neutral to acidic values, they change from purple to red or pink, providing information about the degree of food spoilage (Yi et al., 2025).

Functional packaging films containing carrageenan can be used to monitor spoilage and extend the shelf life of foods. There are studies evaluating carrageenan within smart packaging systems that provide visual alerts through color changes for packaging foods such as meat, fish, and bananas (Han et al., 2025; Jia et al., 2025; J. Liu et al., 2018; Ramadas et al., 2024; J. Wang et al., 2024). Table 1 summarizes various studies on the utilization of freshness indicators in smart packaging systems.

Table 1. Various studies on the utilization of freshness indicators in smart packaging systems

Pigment	Food	Film Material	Color Change	Reference
Carrageenan	Beef	Sodium carboxymethyl cellulose-based film	From pink to yellow	Cao et al., 2024
Curcumin	Shrimp	Hydrogel film	From yellow to red	Zhang et al., 2021
Red cabbage-Beetroot extract	Shrimp	Sodium alginate	From red to yellow	Öztürk & Gündüz, 2025
Cresol red and Bromocresol purple	Fish	Polytetrafluoroethylene and polyvinylidene fluoride	From yellow to purple	Kim et al., 2023

In a study, smart indicator films based on carrageenan and sodium carboxymethylcellulose, containing composite anthocyanins (purple cabbage and dragon fruit extract) encapsulated with zein and gellan gum were developed to monitor beef freshness during storage at 4°C. It was reported that the film color changed from pink to yellow in the presence of ammonia, which is released during meat spoilage, and that these color changes were clearly observed during the spoilage (Cao et al., 2024).

Zhang et al. (2021) developed an agar and polyvinyl alcohol-based indicator containing curcumin to monitor shrimp freshness. During the storage period (4°C for 3 days), the indicator

color changed significantly from yellow to red due to shrimp spoilage, and a distinct color change was observed in the presence of ammonia.

An ammonia-sensitive, colorimetric freshness indicator was developed to assess the freshness of fish during storage. The indicator, formulated using cresol red and bromocresol purple, monitored the spoilage process in various fish species stored under different temperatures through ammonia detection. It was reported that the indicator successfully tracked the freshness of the fish by exhibiting a color change from yellow to purple as the storage period increased (Kim et al., 2023).

Time-temperature indicator

Time-temperature indicators are systems that visually reflect changes in food quality and shelf life by monitoring the temperature history of food exposure. These indicators change color in response to a specific time and temperature combination. This color change parallels the spoilage process of the product. Time-temperature indicators can simplify cold chain monitoring and reduce the risk of spoilage (Gao et al., 2020).

Time-temperature indicators are generally reliable tools for predicting food quality attributes; however, their predictive performance can sometimes be limited. This is mainly due to the instability of the chemicals used in their formulation and the differences in temperature sensitivity between the indicator and the food product. To address this, storage studies are conducted to establish a calibration curve that correlates the indicator's color changes with the actual quality of the food. However, when there is a mismatch in temperature sensitivity between the food and the indicator, the calibration curve generated under constant temperature conditions may no longer be valid. This creates challenges in developing a consistent and representative curve. For the indicator to be considered accurate and reliable, it is crucial that it must be capable of reflecting food quality consistently with a single calibration curve, even under variable conditions (Upadhyay et al., 2024).

In a study, an application was developed for the digitally monitor time-dependent temperature changes of ready-to-eat salads under both laboratory and real-time supply chain conditions. Sliced carrots were identified as the main component limiting the product's shelf life. The predictions from the time-temperature indicator generally aligned with the actual shelf life of the product. However, deviations were observed in cases where temperature fluctuations occurred. These deviations were particularly associated with rapid color changes in the indicator at 2°C and 7°C, resulting in shorter predicted shelf life compared to the actual product (Waldhans et al., 2025a).

(Yar et al., 2025) developed a packaging film incorporating a time-temperature indicator composed of amaranth leaf extract, polyvinyl alcohol, and citric acid to monitor beef freshness. It was reported that the packaging film is not only capable of detecting temperature fluctuations in the environment but can also be effectively used to assess the beef freshness.

In another study, an application was developed to predict the shelf life of pork sausages throughout the supply chain using time-temperature indicators. In the study, a spoilage kinetics model based on microbial parameters was created for pork sausage, and this model was integrated with data obtained from the time-temperature indicator to form a dynamic system. The findings showed that the time-temperature indicators and the product spoilage kinetics were comparable, demonstrating that the developed application is conceptually valid for predicting the shelf life of pork sausage. Additionally, it was reported that technical improvements to the system could further enhance the accuracy of shelf life predictions (Waldhans et al., 2025b).

pH indicator

Various metabolites released during food spoilage provide important information about the freshness and safety of the product. In particular, metabolites such as CO₂, histamine, and dimethylamine are directly related to spoilage, and the pH changes caused by these metabolites can negatively affect the quality of the food. The detection of such metabolites has become possible through the pH and gases sensitive indicators incorporated in smart packaging systems. These indicators enable real-time monitoring of product quality, offering reliable information to both producers and consumers (Zhu et al., 2024).

In recent years, biodegradable and non-toxic plant-based natural pigments have gained attention as alternatives to synthetic pigments (such as bromocresol purple, methyl red, cresol red), which pose potential risks to both the environment and human health (Jebel et al., 2025). Moreover, natural pigments obtained from the valorization of agricultural and food industry waste offer a sustainable alternative. These pigments are typically incorporated into biopolymers such as polysaccharides, lipids, proteins, or polyvinyl alcohol to form films, which are effectively used in smart packaging systems (Panwar et al., 2024).

The integration of pH-sensitive pigments into smart packaging systems has emerged an effective method for monitoring food spoilage. During storage, changes in pH interact with the conjugated structures or phenolic components of these pigments, resulting in visible color changes. Since these color changes can be easily perceived visually by the consumer, they offer the advantage of providing quick and practical information about the freshness of the product (Parlak et al., 2024).

The main reasons for using pH-sensitive natural pigments as indicators in smart packaging systems include their non-toxic nature, water-soluble structures, pH responsive color-changing properties, and even anticancer effects (Zhao et al., 2023). In this context, natural pigments such as anthocyanin, curcumin, alizarin, shikonin, and betalain are commonly used in pH-sensitive smart packaging applications (Liu et al., 2025; Parlak et al., 2024).

Alizarin, a natural indicator dye, is a non-toxic compound derived from plant extracts and can be used as a pH indicator in smart packaging systems. Alizarin dissolves easily in polysaccharide-based films without requiring chemical modification, making it a safe and suitable pigment for use in polymer-based smart packaging systems (Li et al., 2024). Shikonin is another notable compound in smart packaging applications due to its pH-sensitive nature and antimicrobial properties. However, its use in smart packaging systems remains limited because of challenges such as poor water solubility, low stability, and difficulties in maintaining its functionality (Sun et al., 2025b) Table 2 presents various studies on the utilization of pH indicators in smart packaging systems.

Table 2. Various studies on the utilization of pH indicators in smart packaging systems

Pigment	Food	Film Material	Color Change	Reference
Anthocyanin	-	Cellulose Chitosan	From blue-green to yellow	Hailu et al., 2025a
Curcumin	Chicken fillet	Artocarpus lakoocha starch-based film	From yellow-red to orange	Mali & Pandey, 2024
Blueberry and blackberry pomace	-	Chitosan	From red to purple	Kurek et al., 2018
Plum peel	Chicken	Sodium alginate, Gelatin	From red to yellow-green	Chen et al., 2023

In a study, an intelligent packaging film was developed using curcumin as a pH indicator and starch derived from *Artocarpus lakoocha* seed waste. Although the film exhibited reduced

mechanical properties, increases in water vapor transmission rate and crystallinity was observed. Moreover, the film demonstrated antioxidant and antibacterial activities in meat products and proved to be an effective pH indicator (Mali & Pandey, 2024).

Hailu et al. (2025) developed pH-sensitive smart packaging films by combining anthocyanins obtained from pea flowers and red cabbage extracts with a cellulose-chitosan matrix. Their study reported that these films possess superior properties and can be used as freshness indicators in food packaging.

In another study, chitosan-based smart packaging films were developed using blueberry and blackberry pulp extracts. The films exhibited distinct color changes depending on pH variation, with blueberry films changing from rose to blue-green, while blackberry films shifted from red to dark violet. The most pronounced color changes were observed in the pH range of 4–7, which reflects food spoilage. Therefore, it was concluded that these films have potential for use in detecting food spoilage (Kurek et al., 2018).

Chen et al. (2023) developed pH-sensitive films containing sodium alginate, gelatin, and plum peel extract to monitor the freshness of chicken meat. It was found that the developed films exhibited a distinct color change from red to yellow-green over a pH range of 1 to 14, demonstrating high pH sensitivity. Furthermore, during the storage of chicken at 4°C for 6 days, the film's color changed from orange-pink to yellow-green as spoilage progressed, indicating its effectiveness used as a smart packaging material for monitoring the freshness of chicken meat.

A pH-sensitive biopolymer film containing betacyanin and carbon dots was developed using soy protein and methylcellulose to monitor the spoilage of shrimp. In the study, the pH-sensitive color change properties of the developed biofilms were examined. As the spoilage of shrimp progressed, the indicator color shifted from pinkish brown to yellow, reflecting an increase in environmental pH (Ebrahimi et al., 2025).

Ripeness indicator

Ripeness indicators are systems that visually show consumers whether a food is ready for consumption, its ripeness, and freshness. These indicators respond to gases released by fruits and vegetables, especially ethylene, by changing their color. This helps consumers easily select products at their ideal ripeness, thereby contributing to the reduction of food waste (Palanisamy et al., 2025). In the reliable assessment of fruit ripeness, it is important for the indicator to detect ripening markers, such as ethylene gas, on-site and to be cost-effective. Accordingly, researchers have recently focused on developing odor visualization technologies. However, dye-based sensors used to detect the low concentrations of ethylene gas released from fruits and vegetables may be insufficient in detection processes due to limitations such as low signal output and high-dimensional data outputs (You et al., 2024).

In a study on the detecting banana ripeness and delaying spoilage through the integration of machine learning techniques and IoT technologies, it was reported that the machine learning algorithms provided high accuracy in predicting the ripening stages of bananas (Rajini & Voola, 2025). In another study, an ethylene gas-sensitive indicator containing aluminum and nitrogen-doped carbon quantum dots embedded in an agar film was developed to determine banana ripeness. It was reported that this indicator demonstrated successful results in the qualitative detection of ethylene gas produced during ripening (Lohrasbi Nejad & Shekarchizadeh, 2025).

Spoilage indicator

Spoilage indicators are used to detect microbial activity by interacting with enzymes or secondary metabolites produced by microorganisms responsible for food spoilage. Compounds such as diacetyl, amines, carbon dioxide, ammonia, and hydrogen sulfide, produced by microorganisms, react with indicators integrated into packaging systems, causing visible color

changes (Pereira et al., 2024). In addition to these visual indicators, electrochemical sensors, RFID tags, and biological and enzymatic analysis methods are also used for detecting food spoilage. However, the high cost of these systems along with challenges in production and packaging integration, limits their widespread use in packaging applications. Therefore, researchers continue to work on developing practical, low-cost, and user-friendly spoilage indicators that enable on-site and real-time detection of spoilage in foods (Liu et al., 2025)

Liu et al. (2025) conducted a study in which a bacterial nanocellulose film produced from fermented sour whey, was functionalized with anthocyanins derived from *Clitoria ternatea* to design a pH-sensitive smart label system for detecting spoilage in meat. The study demonstrated that the color changes exhibited by the film in response to spoilage could enable real-time monitoring of quality changes in meat through smart packaging systems.

In a study, a smart packaging system was designed by integrating a pH indicator containing encapsulated bromothymol blue as a label into a polyethylene packaging film to monitor spoilage during storage (4°C, 15 days) of chicken fillets. It was reported that the developed films successfully detected pH changes associated with microbial spoilage in chicken fillet samples by exhibiting color changes (Ibrahim et al., 2025).

Sensors

Smart packaging systems utilize various sensors to monitor quickly, accurately, and reliably environmental factors that impact product quality. These systems, particularly used in the packaging of dairy products, seafood, and fresh food, significantly contribute to reducing food waste and protecting consumer health by monitoring food content (Wang et al., 2025). One of the most notable technologies in these systems is biosensors. Biosensors are manufactured using materials that can react electrochemically and change color, and are integrated into packaging materials to detect chemical and microbial changes in foods and monitor their current condition (Sobhan et al., 2025).

Şekil 3. Basic components used in biosensor production (Feng et al., 2025)

Figure 3 shows the basic components used in the production of biosensors. Different types of biosensors are used for the detection and analysis of physiological changes occurring in food products, such as food toxins, chemical contaminants, spoilage indicators, food enzymes, food pathogens. In this context, optical, electrochemical, acoustic, and gas biosensors are particularly notable (Bodkhe et al., 2025; Rodrigues et al., 2021a; Sobhan et al., 2025; Upadhyay et al.,

2024). These biosensors operate in different ways according to their signal transduction mechanisms during analyte detection, and this classification is detailed in Figure 4.

Figure 4. Biosensors classified according to their signal transduction mechanisms (Bodkhe et al., 2025; Damborský et al., 2016; Hammond et al., 2016; Pohanka, 2017)

Recently, colorimetric sensors, which allow for simple and equipment-free detection of analytes, have become the focus of research. These sensors enable easy detection of spoilage in food through color changes resulting from interactions with analytes, and they can also be integrated into or attached to packaging (Najafi et al., 2025). However, a large portion of current sensors are made from nonbiodegradable and nonrenewable synthetic materials. Considering environmental impacts, this situation is increasingly driving the demand for the development of sustainable, eco-friendly smart biosensor materials (Rodrigues et al., 2021b). In smart food packaging sensor applications, pathogen biosensors that detect the presence of pathogens, pH and temperature biosensors that monitor changes in acidity, and gas biosensors that detect gases produced as a result of spoilage are generally used (Mani et al., 2025).

Pathogen biosensor

Pathogen biosensors are electrochemical biosensors developed based on target-specific biological recognition elements such as enzymes, antibodies, and nucleic acids to detect the presence of pathogens in food. These biosensors operate by producing electrochemical signals that determine microbial load and concentration levels through the binding of biological recognition elements and electrochemical transducer materials to pathogen cells (Sobhan et al., 2025).

Jeyaraman and Eltzov (2025) developed an alginate-gelatin-based biosensor system for the rapid and specific detection of *Bacillus subtilis* in food. It has been reported that this system, tested in complex food matrices such as rice and milk, can respond rapidly even at low bacterial concentrations and may be useful for early contamination detection.

A triple-signal biosensor has been developed for the simultaneous and sensitive detection of both live and dead forms of *Listeria monocytogenes*. The developed biosensor could detect live bacteria with a detection limit of 1 CFU/mL and total bacteria with a detection limit of 5 CFU/mL. Therefore, it is reported that the biosensor can be used for the simultaneous and highly sensitive detection of both live and dead bacteria in terms of food safety (Zhang et al., 2025).

pH and temperature biosensors

Thermochromic materials used in smart food packaging systems serve as temperature sensors due to their ability to change color in response to temperature variations. These sensors exhibit irreversible color changes during food storage, providing continuous monitoring throughout the product's shelf life. When the food reaches a critical temperature, the color change becomes permanent, offering visual information to the consumer about storage conditions and supporting safe consumption (Pereira et al., 2024).

Yildiz et al. (2021) developed curcumin-loaded chitosan and polyethylene oxide-based electrospun nanofibers to monitor the freshness of chicken meat and investigated the potential use of these materials as halochromic pH sensors. The curcumin-loaded nanofibers exhibited a color change from bright yellow to red on chicken breast, effectively providing a visual indication of spoilage. The study reported that the developed nanofibers could be used as an efficient sensor system for real-time monitoring of chicken meat freshness.

Wang et al. (2024) developed a label-free and novel DNA sequence-based poly-dA20 pH-sensitive colorimetric biosensor system working with gold nanoparticles for the evaluation of food freshness. Visible color changes in the gold nanoparticle solution were observed during the storage (4 °C and 25 °C) of meat and sea bass samples, corresponding to pH variations. The study demonstrated that the developed pH-sensitive biosensor could be effectively used for detecting food spoilage.

Gas biosensors

Gas sensors consist of three main components: the sensing, counter, and reference electrodes, which work together to detect gases. When the sensing electrode reacts with the gas present in the product, the counter electrode balances this reaction, while the reference electrode measures the potential change. This setup ensures the reliability and sensitivity of the sensor (Upadhyay et al., 2024). Gas sensors used in food packaging provide information to consumers about the product's condition by producing distinct color changes when reacting with metabolites, thereby contributing to the proper assessment of the product (Zhu et al., 2024).

Among the semiconductor metal oxide compounds used in gas detection sensors, compounds such as tin dioxide (SnO₂), zinc oxide (ZnO), tungsten trioxide (WO₃), copper oxide (CuO), and nickel oxide (NiO) are commonly used for the detection of hydrogen sulfide (H₂S) gas released during meat spoilage (Fang et al., 2025). Additionally, studies using pH indicators such as methyl red and brilliant cresol blue for the detection of ammonia (NH₃) gas released during the spoilage of fish and meat products are also found in the literature (Liu et al., 2025).

Fang et al. (2025) developed composite biosensors containing titanium oxide doped with copper oxide and nickel oxide, as well as quantum dots, for the evaluation of meat freshness. These biosensors enabled effective and rapid monitoring of meat freshness by detecting hydrogen sulfide gas with a sensitivity of 100 ppb. The study reported that the sensor demonstrated superior gas detection performance.

FUTURE PERSPECTIVES AND CHALLENGES

In the field of biopolymer-based food packaging, numerous research and industrial studies are ongoing on the integration of bioactive compounds such as metal nanoparticles, plant-derived polyphenols, and volatiles into polymer matrices (Periyasamy et al., 2025). However, although the indicators and sensors developed within the scope of smart packaging systems have shown promising results under laboratory conditions, they have not yet been commercialized and mostly remain at the research stage. The high cost of indicators and sensors, the challenges in integrating them into production and packaging processes, and the adverse effects of thermal treatments applied in large-scale film production on their properties

all slow down the commercialization process. Therefore, it is necessary to develop durable, low-cost indicators and sensors suitable for commercial use (Huang et al., 2025).

Researches on sustainable packaging systems offer significant advantages both in meeting consumer demands and in integrating environmentally friendly materials. Advances in sensor technologies and data analysis not only facilitate food preservation and transportation but also have the potential to bring about a fundamental transformation in the field of packaging through the use of alternative technologies (Baneshi et al., 2024). However, although biopolymer-based packaging materials are a promising alternative, they must overcome significant challenges, such as good mechanical performance, sustainable raw material supply, and market acceptance, to replace traditional plastic packaging (Venkatesan et al., 2025).

CONCLUSION

Smart biopolymer-based packaging systems have significant potential in food packaging due to their advanced features, including user-friendliness, environmental compatibility, and the ability to provide information about the product. These systems are considered advanced technological applications, as they monitor quality parameters such as freshness, pH, and the presence of pathogens in food. Although laboratory studies have demonstrated the practical benefits of these systems, their production on an industrial scale remains limited.

There are certain technical challenges that hinder the widespread adoption of biopolymer-based smart packaging in the food industry. Disadvantages such as poor mechanical strength, inadequate moisture resistance, and low thermal stability limit their large-scale application. In addition, the scalability and efficiency of production methods are also important factors that need to be considered.

The integration of advanced production techniques with biopolymer-based smart packaging films significantly contributes to sustainability goals and supports the circular economy approach. The use of components derived from renewable biomass not only increases resource efficiency but also positively impacts the development of bioeconomy applications.

Consequently, the widespread use of biopolymer-based smart packaging systems requires attention not only to technological advancements but also to issues such as material safety, biocompatibility, data security, and regulatory compliance. Further research and development efforts are necessary to overcome current limitations and support the advancement of this field.

ENHANCING ENERGY EFFICIENCY IN AGRICULTURAL PRACTICES

Burcin ATILGAN TURKMEN

Corresponding author e-mail: burcin.atilganturkmen@bilecik.edu.tr

ABSTRACT

Energy efficiency is one of the areas that must be carefully addressed in the agricultural sector due to its direct relationship with the long-term viability of economic growth and social development goals, as well as its critical role in lowering greenhouse gas emissions. Energy efficiency refers to determining how to reduce energy consumption while maintaining the same production and service levels. This study examines the importance of energy efficiency in the agricultural sector and the energy efficiency practices that can be implemented at various stages of agricultural production. Understanding energy consumption is essential before assessing energy efficiency initiatives. Agriculture uses energy either directly or indirectly. Determining and documenting the energy inputs, as well as creating the required energy plans, are essential. The use of tractors and agricultural equipment, irrigation systems, greenhouse heating and cooling systems, and fertilizer and pesticide application are examples of energy-intensive activities in the agricultural sector. Furthermore, educating producers about energy efficiency and the importance of tracking and revealing energy consumption raises awareness and helps efficiency initiatives succeed. Increasing energy efficiency in farms typically costs less than installing new energy production systems. The development and implementation of integrated energy efficiency measures are also critical for production sustainability. Energy efficiency in farms and throughout the supply chain will help offset rising energy costs for heat, electricity, gas, and liquid fuels. This is also critical for increasing profits while protecting natural resources, minimising environmental impact, and ensuring the long-term viability of agricultural production.

Keywords: Energy, Smart farming, Energy-saving techniques, Sustainable food systems, Energy efficiency

INTRODUCTION

Agriculture is a critical sector that enables the production of food required for human survival. This sector is extremely important in economic, social, and environmental terms. Modern agricultural practices, which use various methods to meet the increasing food demand, have largely replaced primitive agriculture (Finan, 2019). Modern agricultural production processes have resulted in a shift from the widespread use of human or animal power to mechanical energy using fuels (Sial et al., 2021). This agricultural sector has become dependent on energy sources such as oil and electricity, just as other sectors have (Bekhet & Abdullah, 2010). In this context, energy efficiency is crucial because it influences various operations, including resource consumption and production.

ENERGY EFFICIENCY

Energy is the capacity to perform tasks. Renewable and non-renewable (fossil) energy sources are typically classified into two major categories. Although coal, oil, and natural gas are non-renewable energy sources, solar, wind, biomass, and hydroelectric power are renewable energy sources. Fossil fuels continue to provide a significant amount of today's energy needs, which poses major challenges to the sustainability of the environment (BP, 2020; IEA, 2021). Therefore, energy efficiency is becoming increasingly important.

Energy efficiency refers to achieving the same or higher production level by consuming fewer existing energy resources (EnVer, 2023). Usually expressed as a percentage between 0% and 100%, energy efficiency is the quantity of energy produced for a specific energy input. Energy efficiency can be increased at many stages of the energy production–consumption chain. Energy efficiency is a key policy component in many developed nations (ETKB, 2023; Yildiz et al., 2017).

Energy efficiency refers to efforts to reduce or, if possible, eliminate unnecessary energy consumption. Energy efficiency does not imply reducing or restricting energy demand; rather, it involves lowering the amount of energy consumed per product rather than the rate of energy consumption (ETKB, 2023).

ENERGY USE AND AGRICULTURE

Energy is a critical input in all stages of agricultural production. In the agricultural sector, energy use in plant and animal production processes is classified into two types: direct and indirect (Schnepf, 2004). Direct energy consumption in this sector includes energy used in agricultural activities such as harvesting, irrigation, drying, storage, greenhouse heating, and marketing, as well as energy used in infrastructure, agricultural machinery, tractors, and trucks (Martinho, 2021). Indirect energy consumption is typically found in the industrial sector and refers to the energy used in the production and processing of mineral fertilizers, chemical pesticides, insecticides, herbicides, and other agricultural chemicals (Schnepf, 2004).

Tractors, harvesters, lights, pumps, and heaters all consume considerable amounts of fuel and electricity, and the production of chemical inputs is also an energy-intensive process. Energy consumption is especially high in developed and heavily farmed agricultural areas, affecting both the economy and the environment. Although the use of fossil fuels harms the environment by increasing greenhouse gas emissions, the high energy dependence of agricultural production increases production costs (Vijayakumar et al., 2023).

ENERGY EFFICIENCY AND AGRICULTURAL PRACTICES

Enhancing agricultural energy efficiency is essential for reducing production costs and maintaining environmental sustainability. Efficient energy use has positive effects on the economy and the environment by lowering energy consumption per unit of product. Therefore, energy efficiency is crucial for agricultural advancement.

In a crop and livestock farm, daily operations include agricultural machinery, greenhouses, dryers, buildings, irrigation systems, and farm equipment, all of which lead to high energy consumption (Stephen Herbert, 2021). Increased agricultural energy efficiency by implementing day-to-day structural and technological measures.

Energy management requires the reduction of the amount of fuel used in field applications. Field applications must maximize the use of tractors and other tools and machinery

to achieve this (Stephen Herbert, 2021). It is important to change the filters, oil, tires, and balance, calculate the power requirements, and determine the optimal operating conditions for vehicles used in the field. Excess vehicle weight should be minimized to reduce fuel consumption (Carbon Trust, 2019; Mutlu, 2020). If there are fuel tanks on the farm, keep them cool to reduce fuel evaporation and regularly check for leaks. Vehicles running at idle can consume up to one-fifth of the total fuel consumption; therefore, machines should be turned off when they are not in use (Stephen Herbert, 2021; Susser, 2018).

Lighting is also required in agricultural buildings, greenhouses, poultry houses, and barns. Transparent panels, such as light tubes, are used to provide natural lighting (Can, 2023). Additional light sources are employed in areas where natural light is insufficient. LED bulbs should be used to provide energy-efficient lighting (Singh et al., 2015). Furthermore, an automatic lighting control system offers the most efficient lighting with the smallest number of lights (Carbon Trust, 2019).

Identifying and implementing ventilation system improvements can reduce energy consumption by up to 20%. Every farm requires effective ventilation; however, windows and doors that allow natural ventilation should be used whenever possible. Replacing old ventilation fans with more efficient ones reduces energy consumption. Therefore, the fan blades and broils should be ventilated regularly (Carbon Trust, 2019).

Irrigation and animal watering systems can be designed to save energy. Proper pump selection, low-pressure irrigation, drip irrigation, and distribution system optimization are required to water crops. Wherever possible, rainwater should be used to construct irrigation systems. Replacement of diesel pumps with electric pumps for irrigation improves efficiency, reduces operating costs, and increases reliability. Smart sensors can help irrigation systems run more efficiently. Using thermal insulation and automatic heating systems, animal waterers can save energy by preventing water from freezing (Iliev et al., 2012; Stephen Herbert, 2021).

In some cases, drying a product requires more energy than growing it. A moisture meter should be used to ensure that the product is dry. If mechanical drying is necessary, a natural air or low-temperature drying system can be used (Stephen Herbert, 2021).

The use of renewable energy sources in agriculture is an important strategy for promoting energy efficiency. Successful applications in this field include solar-powered irrigation systems, wind-powered water pumps, and biogas systems derived from agricultural waste (Atılğan Türkmen, 2020).

CONCLUSIONS

Enhancing the energy efficiency of agricultural practices is essential for environmental protection and sustainable economic growth. Agriculture can become more economical, ecologically friendly, and efficient through the integration of cutting-edge technologies and renewable energy sources. Regarding these issues, farmers require education and assistance. Achieving energy efficiency in agriculture supports efforts to fight climate change, conserves natural resources, and lowers greenhouse gas emissions. Consequently, agricultural policies and practices should incorporate EE as a fundamental component.

ABSTRACT

Encapsulation technology is needed to make more durable and effective of alternative natural preservatives and nutritional components. In recent years, liposomal structures have attracted attention and liposomes ensure the preservation of the encapsulated material until the appropriate place and time thanks to controlled or delayed release capability. Liposomal structures prevent the conversion into harmful components during storage and increase the bioavailability. The liposomal encapsulation process provides to be more stable and more durable bioactive compounds in the food and the digestive system. The slowly release of antimicrobial components during storage against microbiological contaminations can be realized without allowing mold contamination and mycelium formation in food products. In addition, which will be carried out on non-chemical "hurdle" technologies in order to control the development of food-borne microorganisms and increase antioxidant activity in order to respond to consumer expectations, aims to produce product formulations suitable for the concept of 'Clean Label'. In addition, in order to respond to consumer expectations, it is possible to control the development of food-borne microorganisms and to produce product formulations in accordance with the concept of 'Clean Label' with liposomal systems suitable for "hurdle" technologies without chemical content.

Keywords: Liposom, natural preservation, bioactive compounds, Clean Label

INTRODUCTION

Bioactive components have important antioxidant and antimicrobial effects and also effective on human health. Encapsulation procedures have implemented to increase the mechanism of bioactive components' action. Liposome encapsulation is an important application thanks to provide the development of controlled release of bioactive components in food and increased stability. One of the biggest advantages of liposomes is to made from natural components. Liposomes can be included in food formulations without the need for any legal regulation due to natural structure. Liposomes are no usage limit compared to chemical origin substances, and so excessive limits lead to no health problems. This feature removes the obstacles to the use of liposome structures in foods.

Liposomes are used to improve the water dispersibility of hydrophobic components, to increase bioavailability and to protect the encapsulated components from adverse conditions such as light, heat, pH, oxidation, hydrolysis or chemical reactions, to enable the delivery of an encapsulated agent to a specific location, to reduce negative effects and particle toxicity. Liposome systems provide to control the circulation in the body by modulation of their size and regulating the release profiles with surface modifications of the bioactive components (Alavi et

al., 2017; Lila and Ishida, 2017). Unlike other encapsulation methods, liposomal structures have no negative effect on product rheology properties thanks to very low phosphorylcholine-based lecithin concentration. In addition, the encapsulated components are more resistant to processes such as cooking and pasteurization with the controlled release of bioactive substances in the liposomal structure.

ENCAPSULATION TECHNIQUES

Encapsulation is an excellent method for the preservation of bioactive, volatile and readily degradable compounds and additives in food applications. The purpose of encapsulation is to protect active ingredient from external factors, to ensure stable in the digestive system and to release slowly, to increase bioavailability, to mask the negative taste and odor, and to prevent the active ingredient from reacting with other ingredients (Delshadi et al., 2020). In the encapsulation process consists of the active components as the core material and the appropriate wall material. The coating agent plays a key role and an ideal coating material should have low hygroscopicity, high solubility, low viscosity, low cost, ability to produce a stable emulsion and provide high protection (Gomez et al., 2018). Lipids, proteins and carbohydrates are widely used as coating material in encapsulation systems. The coating materials are desirable to be inexpensive, plentiful, non-toxic, and compatible with the food matrix (Jafari et al., 2008; Delshadi et al., 2020).

Lipid-based coating agents have excellent functionality in emulsification, film formation and encapsulation of active compounds. These coating materials are less toxic and have many potential uses in industrial applications (Fathi et al., 2012). The lipid-based coating materials are polar lipids (eg monoglycerides, phospholipids) and non-polar lipids (eg triacylglycerol, cholesterol) (Đorđević et al., 2016). Polar lipids such as phospholipids have some properties as biocompatible, suitable for stabilization, preservation and controlled release of active compounds and good surfactants (Đorđević et al., 2016; Shishir et al., 2018). Encapsulation contains microcapsules, submicron capsules, and nanocapsules sizes. Micro and nano encapsulation techniques include high pressure homogenization (HPH), micro fluidization, ultrasonic technique, spray drying, spray cooling/cooling, freeze drying, spray freeze drying, complex coacervation, emulsification (spontaneous, phase inversion, miscellaneous), anti-solvent precipitation, extrusion, electro-spinning and electro-spraying, layer deposition, solid dispersion, fluid bed coating, molecular inclusion in cyclodextrins. Different forms of micro and nano encapsulation systems are reservoir and matrix, emulsions (multilayer emulsions, nano emulsions), lipid nanoparticles (solid lipid nanoparticles (SLNs), nanostructured lipid carriers (NLCs), lipid vesicular carriers (liposomes, niosomes, phytosomes, bilosomes), hydrogel particles, molecular inclusion complexes, nanofibers, nanotubes, micelles.

LIPOSOMAL ENCAPSULATION LIPOSOMES

Liposomes are basically amphipathic vesicles in phospholipid structure, similar in structure to the cell membrane, with polar and nonpolar heads and double lipid layer structure. Liposomes are versatile, biocompatible and biodegradable structures that can be used as carrier systems for unstable components due to their amphipathic properties (Subramani and Ganapathyswamy, 2020). Liposomes were first described in 1965 by Bangham et al. (1965) are small intracellular shaped structures consisting of a closed membrane storing or transporting lipid-based substances. Phospholipids are one of the main groups providing liposome formation. Phospholipids are mainly composed of three-carbon alcohol, glycerol or sphingosine. Common alcohol components of glycerol-derived phospholipids are called phosphatidylserine (PS), phosphatidylcholine (PC), phosphatidylethanolamine (PE),

phosphatidylglycerol (PG), and phosphatidylinositol (PI). Phospholipids are formed by esterification of the primary hydroxyl group of glycerol with phosphoric acid. The remaining two hydroxyl groups of the glycerol backbone are esterified to fatty acids (saturated or unsaturated) and form the nonpolar tails of the lipid (Segota and Tezak, 2006). Liposomes consist of two layers of molecules with nonpolar groups. In the liposomal structure, polar head groups are directed outward, while non-polar parts are directed inward. Hydrophobic interactions and Vander Walls bonds that hold long hydrocarbon tails together play an important role in bilayer formation (Bozzuto and Molinari, 2015).

Liposomes are divided into different categories based on their structural properties and composition. Liposomes differ from each other in size and physical morphology, depending on lipid composition and preparation method, and may consist of one or more lipid bilayers. The phospholipid type influences the dimensions and physicochemical properties of the liposomes (Singh et al., 2012). Liposomes according to the composition and mechanism of intracellular delivery as follows: pH sensitive liposomes, conventional liposomes immuno-liposomes, cationic liposomes and long-circulating liposomes (Sharma and Sharma, 1997). Generally, the size change from 20 nm to 5000 nm and consist of one or more lipid bilayers. Liposomes according to lipid composition; preparation method and diameter as follows: multilamellar vesicles-MLV (>500 nm), small unilamellar vesicles-SUV (<50 nm), large unilamellar vesicles-LUV (100-1000 nm), giant unilamellar vesicles-GUV (>1000 nm), Multiple vesicles-MLV (>5000 nm), Oligomellar vesicles-OLV (100–1000 nm) and intermediate unilamellar vesicles-IUV (40-100 nm) (Lasic, 1998; Storm and Crommelin, 1998).

LIPOSOME PRODUCTION METHODS

Bangham method (thin film hydration method); One of the simplest methods for liposome formation in multilamellar vesicles is the thin-film hydration procedure. Thin-film hydration method is the most widely used technique to prepare liposomes (Bangham et al., 1965). The thin-film hydration method consists of sequentially dissolving phospholipids in an organic solvent (mostly chloroform), evaporating the solvent to form a thin film, and then dispersing the dry lipid film in an aqueous phase. In this method, sonication is used to reduce the size of large-sized liposomes (Maja et al., 2020). Apart from this, the methods applied are as follows, solvent (ether or ethanol) injection method, reverse phase evaporation (REV), dialysis, extrusion, spray drying, heating, freeze drying, cross flow injection, microfluidization, membrane contactor, supercritical reverse phase evaporation (SCRPE), improved SCRPE method (ISCRPE), supercritical antisolvent (SAS), depressurization of an expanded liquid organic solution-suspension (DELOS) and ultrasonication method. Each of these methods has different advantages and disadvantages.

LIPOSOMAL ENCAPSULATION METHOD PROPERTIES

Liposomes are preferred in the encapsulation process thanks to biocompatible, biodegradable, no show toxic effects, and high ratio protect of coated material (Laye et al., 2008; Gibis et al., 2012; Chun et al., 2013). One of the most important features of liposomes is that can be obtained from nature components. The natural structure of liposomes enables the usage in food systems without the need for any legal regulation (Taylor et al., 2005). In food science, the liposomal encapsulation method is used to encapsulate antioxidant components, antimicrobial components, enzymes and additives. The liposomal system is used in the encapsulation of many bioactive components, including fatty acids such as gambogenic acid (Tang et al., 2018), resveratrol (Caddeo et al., 2008), tea catechins (Zou et al., 2014) and linolenic acid (Vélez et al., 2019), omega-3 and protein hydrolysates (Li et al., 2015).

Liposomal encapsulation offers a versatile approach in terms of preservation and controlled release of sensitive bioactive ingredients, delaying food spoilage, protecting bioactive ingredients from degradation after consumption, and increasing the bioavailability of ingredients during adsorption (Liu et al., 2020).

Liposome structures improve the solubility of lipophilic compounds in aqueous solutions or hydrophilic compounds in hydrophobic systems. Thanks to high dispersion in water, liposomes can be used to produce low-calorie and fat-reduced products. In addition, liposomes have an important effect in preventing oxidation, removing negative flavors and reducing the energy density of food products (Farrokh et al., 2017). The structural similarity to the cell membrane provides distribution and release some bioactive components to specific areas in the body (Gabizon et al., 2004; Laye et al., 2008). This unique structure allows liposomal nanoparticles to enter the intercellular space in the body. Liposomes have no adverse effects on health and also many health benefits such as liver protection, memory enhancement and inhibition of cholesterol absorption is revealed in studies.

STUDIES ON LIPOSOMAL ENCAPSULATED INGREDIENTS IN FOOD PRODUCTS AS ANTIMICROBIAL AGENTS

The antibacterial activities of clove oil and liposome-encapsulated clove oil were investigated by Cui et al. (2015) and stated that liposome-encapsulated clove oil can be use efficiently as an antimicrobial agent for *S. aureus* in tofu. In a study by Pinilla and Brandelli (2016) determined the antimicrobial activity efficiency of liposome lysine and garlic extract encapsulated with phosphatidylcholine. Nanoliposome-encapsulated nisin-GE has potential as an antimicrobial formulation for food use. According to results, the use of natural antimicrobial nanoliposomes in dairy products is an important alternative way to improve food quality and shelf life. Lopes et al. (2017) carried out the encapsulation of nisin by nanoliposomes obtained using soybean phosphatidylcholine (PC), pectin or polygalacturonic acid. Antimicrobial activities of liposomes were observed against five different strains of *Listeria*, and showed the highest activity against *L. innocua*. In-vitro release studies have indicated that the nisin release rate of PC-pectin and PC-polygalacturonic acid liposomes is lower than that of PC liposomes.

Ghorbanzade et al. (2017) stated that fish oil has important benefits in the daily diet, but applications in food formulations are limited due to strong odor and rapid deterioration. So, fish oil encapsulated with nano-liposomal process and usage in the yogurt formulation. It has been stated that nano-liposome fish oil capsules provide a significant reduction in acidity, syneresis and peroxide values of yogurt. In terms of sensory properties, the addition of nano-encapsulated fish oil in yogurt shows similar properties with the control sample enriched with free fish oil. Pabast et al. (2018) investigated the effects of lamb meat in capsules containing free or chitosan-nano-liposomal encapsulated *Satureja khuzestanica* essential oil on chemical, microbial and sensory properties of lamb at 4°C for 20 days. As a result of the study, the chitosan-liposom encapsulated essential oil of *Satureja khuzestanica* could be a promising active packaging material to extend the shelf life of lamb. Lopes et al. (2019), lysozyme and nisin were liposomal encapsulated with phosphatidylcholine (PC) and pectin or polygalacturonic acid. The co-encapsulation of lysozyme and nisin with liposome has a synergistic antimicrobial effect on *L. monocytogenes* and *S. enteritidis*, but provides greater inhibition against *L. monocytogenes*. The PC-pectin liposomes used in full-fat and skim milk medium reduced the *L. monocytogenes* population by 2 log cfu/ml in whole milk and 5 log cfu/ml in skim milk at 37°C. The *L. monocytogenes* population remained below the detection limit in milk stored for 25 days under refrigeration temperature. This shows that liposomes can be a promising technology to provide controlled release and stability in complex food systems.

Pinilla et al. (2019) used garlic extract encapsulated with liposome process with phosphatidylcholine and oleic acid as an antifungal agent in bread formulation. They reported that bread samples containing encapsulated garlic extract and free garlic extract (0.65ml/100g dough) were more microbiologically stable and showed mold inhibition for five days compared to control samples. As a result of the study oleic acid and liposomal garlic extract can be used as natural antifungal agents to improve the microbiological stability of cooked food products due to their thermal properties. In a study made by Lin et al. (2022), a bio-responsive composite liposome with silk fibroin, L-fucose and *Litsea cubeba* essential oil were designed for chicken preservation as antibacterial agent and as results indicated that 20% (v/v) of the composite liposomes could inactivate 99% *Campylobacter jejuni* (C. jejuni).

CONCLUSION

Food safety is an important issue for people in the food production process and consumption. In this respect, food production is faced with many technological challenges due to the increasing demand for naturally additive foods. The natural preservative components are significantly affected by environmental conditions and therefore components must be protected by encapsulation. In the food industry, liposomes have been investigated to deliver proteins, enzymes, vitamins, antioxidants and flavors. Many studies indicate that the efficacy of antimicrobial components is increased with liposome encapsulation. The great advantage of liposomes over other encapsulation technologies is their high stability. As a result, it has been demonstrated that there is a significant potential for use of liposome-encapsulated antimicrobials to improve the quality and healthiness of a wide variety of food products.

ABSTRACT

Rapeseed (*Brassica napus* L.), a member of the Brassicaceae family, is a strategic oilseed crop with a high oil content (35-50%) and low saturated fat content. Globally, rapeseed is considered one of the primary raw materials for biodiesel production. In addition, it contributes significantly to agricultural ecosystems as animal feed, a forage plant for bees, and a crop used in rotation systems. Despite Türkiye's favourable climate and soil conditions for rapeseed cultivation, its production has not reached the desired levels. Currently, approximately 50% of Türkiye's vegetable oil deficit is met through imports, highlighting the urgency of expanding rapeseed production as it has the potential to help close this gap. In the past, the cultivation of rapeseed was prohibited due to its high erucic acid and glucosinolate content, which led to a persistent negative perception among farmers. Although double-zero (canola) varieties have since been developed, this negative perception remains. In irrigated areas, alternative crops tend to offer higher returns, whereas in rainfed areas, farmers' adherence to traditional practices reduces rapeseed preference. Moreover, insufficient support premiums and rising raw material costs have diminished the economic appeal of biodiesel. The lack of purchase guarantees, insufficient contract farming practices, and challenges in storage further exacerbate marketing problems. Farmers' lack of knowledge about rapeseed and loyalty to conventional crops hinder the adoption of this alternative crop. Technical challenges such as bird damage, non-uniform ripening at harvest, and the additional cost associated with the use of hybrid seeds also limit production. These issues prevent rapeseed from fully realizing its potential in Türkiye's agricultural sector.

Keywords: Rapeseed, Canola, Agricultural ecosystems, Biodiesel, Erucic acid, Alternative crops.

Canola, a member of the Brassicaceae (Cruciferae) family, is a plant derived from the natural hybridization of *Brassica rapa* and *Brassica oleracea* species (Doğru, 2020). Genetically, it is an amphidiploid species with a chromosome number of $2n=38$ (İşler, 2011). Canola is a preferred vegetable oil source by health-conscious consumers due to its high oil content (35-50%) and low saturated fat ratio (Gizlenci & Acar, 2021). Canola is typically grown as a winter crop, though summer varieties also exist. Depending on the region, it is harvested with a combine harvester in May and June, and its early harvest allows for the cultivation of a second crop, making it a preferred oilseed crop among farmers (Karasalan, 1999). Additionally, its advantages include being one of the earliest flowering plants, thus providing a valuable pasture for bees, its meal serving as high-quality animal feed, enabling oil mills to utilize idle periods due to early harvesting, being processed into oil without requiring dehulling, and serving as an effective crop for rotation.

The canola plant was first cultivated around 2000 BCE in India, later spreading to China and Japan. Its production surged with the onset of World War II, and it is currently the oilseed crop with the highest growth rate. Canola is extensively cultivated in Europe, Canada, and the United States, and it can be easily grown in almost every region of Türkiye (Baran, 2010). There is no definitive information on when canola began to be used as an oil source in Europe. However, Appelqvist (1972) suggested that canola was first cultivated for oil production in the Netherlands in the 17th century. Schröder-Lembke (1989), citing a church tax record from 1421, indicated that canola cultivation in the Netherlands began even earlier. It has been reported that canola was intensively grown in the Rheinland region of Germany, and the oil, being cheaper than olive oil, was used both as lamp oil for lighting and as a frying oil by the poorer segments of the population (Kimber & McGregor, 1995). Consequently, canola oil was used until the mid-19th century primarily for lighting in households and railways, as well as in soap production (Appelqvist, 1972). Due to its slow and odorless burning properties, it is still traditionally used in the sanctuaries of some churches today. However, the golden age of canola oil ended in the second half of the 19th century with the emergence of cheaper mineral oils. Following the invention of steam engines, canola oil, due to its high adhesion to moist metal surfaces, was used particularly during World War II to lubricate machine parts in contact with water on warships. To meet this demand, the first canola cultivation in Canada began in 1943 (Anonymous, 1992).

Canola was introduced to Türkiye during World War II through immigrants from Bulgaria and Romania (Öğütçü & Kolsarıcı, 1979; Özgüven, 1990). Prior to 1980, it was cultivated in various regions, particularly in Thrace, but its cultivation was banned for two years by the Turkish Ministry of Health due to the identification of risk factors such as erucic acid and glucosinolates (İpkin et al., 1990). This ban was lifted with the development of double-zero varieties, and the Turkish Ministry of Health's report dated April 15, 1987, permitted the use of canola oil in human food. To eliminate the negative perception associated with erucic acid and glucosinolates, the newly developed double-zero varieties (with erucic acid and glucosinolate levels reduced below specific thresholds) have been popularly referred to as canola.

In the early 2000s, biodiesel use experienced a rapid upward trend globally. In parallel, biodiesel consumption in Türkiye also increased. Globally, 86% of biodiesel is produced from canola (Gizlenci et al., 2011). As in the rest of the world, vegetable oils are used as raw materials for biodiesel production in Türkiye. Since the 2000s, canola cultivation areas in Türkiye have shown a rapid increase, leading to a corresponding rise in production volumes. Canola seed production, which was 187 tons in 2000, reached 650 tons in 2001 and 1,500 tons in 2002 (Gizlenci et al., 2007). The growing popularity of biodiesel was a significant factor in this increase. During this period, despite not meeting standards, biodiesel met a substantial portion of the diesel needs of construction machinery due to its cost-effectiveness. However, rising vegetable oil prices in subsequent years increased biodiesel unit costs, causing it to lose its price advantage over diesel. The economic appeal of biodiesel, which had driven the expansion of canola cultivation areas between 2000 and 2005, waned, leading to a reduction in cultivation areas. In later years, legal regulations regarding biodiesel were introduced, and mandatory blending requirements were implemented. In 2011, the Energy Market Regulatory Authority (EPDK) mandated biodiesel blending with diesel at 1% in 2014, 2% in 2015, and 3% in 2016, using domestically produced raw materials (Acar, 2014). However, this mandate was repealed due to challenges in raw material supply. Currently, a mandatory blending requirement of 0.5% biodiesel, produced from domestic raw materials, is applied to diesel.

According to 2022 global oilseed crop cultivation data, soybeans lead with 133.7 million hectares, followed by canola (39.9 million hectares), cottonseed (31.4 million hectares), peanuts (30.5 million hectares), palm (30.0 million hectares), and sunflower (29.2 million hectares) (FAOSTAT, 2024). In terms of 2023 regional data, 67.76% of canola cultivation areas in Türkiye are located in the Marmara Region, which accounts for 59.27% of canola production due to its cultivation area (TUIK, 2024). Outside the Marmara Region, Konya province has gained a significant share in canola cultivation and production in recent years.

In Türkiye, canola production is concentrated in the Thrace, Central Anatolia, and Çukurova regions. As of 2021, the canola cultivation area in Türkiye is below 50,000 hectares, with a total production of approximately 100,000 tons (Gizlenci & Acar, 2021). Based on information from the sector, it is reported that in the 2024-2025 production season, the cultivation area reached approximately 600,000 decares; however, due to irregular rainfall and subsequent drought in the autumn of 2024, approximately 20,000 decares of the cultivation area were adversely affected. In Samsun province, the cultivation area has increased, exceeding 10,000 decares in the 2024-2025 season. The primary factor contributing to this increase in Samsun is the distribution of canola seeds to producers under a project implemented by the Samsun Provincial Directorate of Agriculture and Forestry. Approximately 15-20% of Türkiye's total arable land remains uncultivated each year due to fallowing practices. As is known, the adoption of advanced agricultural techniques can eliminate the need for fallowing. In particular, the use of oilseed crops (such as canola, safflower, etc.) in crop rotation systems can help reduce fallow areas.

Globally, canola ranks second in terms of cultivation area and has a wide range of applications; however, several factors prevent it from reaching the desired cultivation levels in Türkiye. This issue is not unique to canola but applies to oilseed crops in general. Türkiye has long been a net importer of oilseeds and their derivatives. Considering that the annual vegetable oil requirement is approximately 1.5 million tons, while domestic production has not exceeded 800,000 tons, the situation becomes clearer. The reasons for the failure to achieve the desired canola cultivation areas can be outlined as follows:

- Due to its historical ban caused by erucic acid and glucosinolate content, canola has a negative perception among producers. This negative image leads farmers to approach canola cultivation cautiously. One characteristic feature of Turkish farmers is their tendency to remember negative experiences for many years, and even when these issues are resolved, their prejudices often persist unchanged.
- One of the most critical parameters in canola cultivation is ensuring that plants reach the 4-6 leaf rosette stage by the time the first autumn frosts begin. Particularly in the 2000s, late-season canola sowings were carried out by the private sector without considering this factor. In these areas, plants were caught by the first autumn frosts at the cotyledon stage before reaching the rosette stage, resulting in complete crop loss. This negative experience has remained etched in producers' memories for many years. To prevent frost damage due to failure to reach the rosette stage, sowing timing must be carefully managed. Depending on the region, sowing should generally be completed between late September and October 20. However, even if sowing is done on time, delayed rainfall or insufficient soil moisture for germination can delay sprouting, potentially leading to frost damage. To mitigate this, sowing should be done in moist soil after rainfall, or, in cases of delayed rainfall, sprinkler irrigation should be used to provide the necessary moisture for germination.

- When planning production, farmers primarily consider the net profit per decare. It is recommended that canola be cultivated in irrigated areas to achieve satisfactory yields and income. Higher yields and profits can be obtained when canola is grown in irrigated fields. However, since alternative crops grown in irrigated areas are perceived to offer higher returns, farmers do not prioritize canola. Consequently, canola is typically cultivated in non-irrigated areas, where its deep root system allows it to provide higher returns compared to alternative crops. Additionally, many farmers are reluctant to abandon their established habits, including their choice of crop types. They are hesitant to shift away from crops they have cultivated for many years. There are valid reasons for this reluctance, such as their thorough knowledge of the cultivation practices for these crops, their ability to quickly and effectively address potential issues, the suitability of their equipment for these crops, the existence of an established market system for their regular crops, and their general aversion to risk, which makes them cautious about adopting new crop types. Another reason for the limited adoption of canola is the lack of sufficient knowledge among farmers about the crop. Additionally, oilseed buyers in the market do not show enough enthusiasm for canola, which prevents them from raising awareness or encouraging producers to cultivate it.
- In the early 2000s, producers viewed canola as an alternative oilseed crop and cultivated it due to its suitability as a crop rotation option. However, during this period, they faced significant marketing challenges. The absence of purchase guarantees and the lack of contract farming arrangements prevented producers from successfully marketing their products. Due to canola's high oil content, long-term storage is not feasible, which further exacerbated difficulties for producers. For instance, during a field day event in Taşova, Amasya province, a remarkably high yield of 430 kg per decare was achieved, but the product remained unsold due to marketing issues. Although producer cooperatives such as Karadeniz Birlik and Trakya Birlik later included canola among crops with purchase guarantees, canola production in the region has not reached desired levels.
- For many years, canola did not receive support premiums, resulting in lower per-unit-area returns compared to alternative crops. Subsequently, canola was included in the support premium program; however, the premium amounts have not been updated to account for inflation for an extended period, rendering them insufficient.
- One of the primary criteria influencing crop choice is marketing challenges. The most effective solution to this issue is contract farming, which is preferred by farmers. For example, sugar beet producers continue cultivation despite undetermined product prices at the time of sowing and the need to meet numerous production requirements. In contract farming, beyond sales guarantees, producers receive support in terms of technical assistance, fertilizers, seeds, and pesticides, positively influencing their preferences. Regarding canola, contract farming is primarily practiced by biodiesel producers for use as a biodiesel raw material. Expanding contract farming could significantly contribute to increasing canola cultivation areas.
- All canola varieties cultivated in Türkiye are hybrids. Canola is approximately 35% cross-pollinated. Due to its hybrid nature and cross-pollination, certified seeds must be used annually, representing an additional cost for farmers accustomed to self-pollinating crops and producing without purchasing certified seeds each year. Seed costs are a critical consideration in production planning. Additionally, canola's one-third cross-pollination rate, combined with the presence of wild mustard—a close relative—in natural environments, can lead to unintended crossbreeding. This may result in erucic acid levels exceeding permissible limits, which is a concern for farmers.

- Vegetable oil processors in Türkiye design their facilities primarily for sunflower seed processing and are reluctant to adapt their systems for other oilseeds. They generally show little interest in oilseeds other than sunflower.
- One of the risks in canola cultivation is bird damage, particularly in small-scale cultivation areas where the damage rate can increase. During the green pod stage, birds squeeze the pods with their beaks to drink the sap, rendering the pods unproductive. Although birds also consume canola seeds, the primary damage occurs during the green pod stage. To mitigate this, cultivation should occur in larger areas or involve multiple farmers to reduce the crop's vulnerability to birds, thereby minimizing and making bird damage more tolerable.
- Canola, highly suitable for mechanized agriculture, is harvested using combine harvesters. However, its flowering period, lasting approximately 45 days, and the sequential ripening of pods from bottom to top complicate uniform maturation and harvesting. While lower pods may be mature, upper pods may not be fully ready for harvest, creating an undesirable situation. Waiting for all pods to mature can lead to pod shattering during harvesting, especially in lower pods, resulting in yield losses. To address this, harvesting is recommended during early morning or evening hours when humidity is relatively high, and pod shattering is minimized, rather than during hot daytime hours.
- Due to its high oil content, canola is difficult and labor-intensive to store. Unlike cereals or legumes, long-term storage is not easily feasible. Even short-term storage requires pile heights not exceeding 20 cm and frequent mixing to prevent heating and molding. Consequently, producers must market their product immediately and lack the option to store it for sale at a higher price later, unlike other storable crops.

The aforementioned reasons discourage producers from cultivating not only canola but also other oilseed crops. However, none of these challenges are insurmountable. With appropriate measures, all these issues can be addressed. Given the strategic importance of oilseed crops, increasing their production is critical to reducing Türkiye's dependence on imported vegetable oils, maximizing the efficient use of national land resources, boosting the national economy, and improving farmers' incomes. Canola is a prime candidate due to its suitability to Türkiye's climate, soil conditions, and crop rotation systems. Therefore, necessary regulations and incentives must be implemented to promote the widespread adoption of canola cultivation.

ABSTRACT

Rapeseed (*Brassica napus* L.) is a significant oilseed crop due to its high oil content (33–50%) and low saturated fat levels. It is widely used in biodiesel production, the food industry, and animal feed, but must be handled carefully because of its content of anti-nutritional compounds. Historically, rapeseed oil was used for lighting, soap production, and machinery lubrication. However, due to the health risks associated with compounds such as erucic acid and glucosinolates, its cultivation and use were temporarily banned in Türkiye in the 1980s. The development of double-zero (low erucic acid and low glucosinolate) varieties led to the lifting of the ban, and these varieties - commonly referred to as “canola”- became suitable for food production. Erucic acid, when consumed in high quantities, can lead to serious health issues including accumulation in cardiac muscle, myocardial lipidosis, anemia, constipation, vision impairment, and an increased risk of lung cancer. Glucosinolates, sulfur- and nitrogen-containing metabolites, play a role in plant defense however it can cause thyroid, liver and kidney problems in animals if present in high amounts in the rapeseed meal. Phytate (phytic acid), the storage form of phosphorus, reduces mineral absorption in non-ruminant animals and may lead to nutritional deficiencies. Nitrate accumulation, which increases with excessive nitrogen fertilization, is associated with health risks in humans such as cancer, dementia, and goiter. Although rapeseed is a strategic crop with low input costs and rotation advantages, the management of its antinutrients factor is critical in production and consumption.

Keywords: Rapeseed, Anti-nutritional, Erucic acid, Glucosinolate, Phytate, Nitrate

INTRODUCTION

The rapeseed plant is an oilseed and forage crop derived from rapeseed varieties. A member of the Brassicaceae family, rapeseed (*Brassica napus*) is an annual plant with a chromosome number of $2n=38$. It is reported that rapeseed is an amphidiploid species resulting from the spontaneous hybridization of *Brassica rapa* and *Brassica oleracea* (cabbage) in nature. Due to cabbage’s Mediterranean origin, the origin of rapeseed is also considered to be Southern Europe. The oil content in mature seeds varies between 33–50% depending on the variety (Gizlenci & Acar, 2021). With the lowest saturated fat content among all vegetable oils, it is particularly preferred by health-conscious consumers.

There is no definitive information regarding when rapeseed began to be used as an oil source in Europe. However, Appelqvist (1972) suggests that rapeseed was first cultivated for oil production in the Netherlands during the 17th century. Schröder-Lembke (1989), citing a 1421 church tax record, indicates that rapeseed cultivation in the Netherlands began even earlier. It is reported that rapeseed was extensively grown in Germany’s Rhineland region, and the oil, being more affordable than olive oil, was used both as lamp oil for lighting and as a frying oil

by lower-income communities (Kimber & McGregor, 1995). Consequently, rapeseed oil was widely used until the mid-19th century, particularly for lighting in households and railways, as well as in soap production (Appelqvist, 1972). Its slow and odorless burning properties still make it a traditional choice in the sanctuaries of some churches today. However, the golden age of rapeseed oil ended in the second half of the 19th century with the emergence of cheaper mineral oils. Following the invention of steam engines, rapeseed oil's high adhesion to wet metal surfaces led to its use in lubricating machinery exposed to water, particularly in warships during World War II, with Canada initiating rapeseed cultivation in 1943 to meet this demand (Anonim, 1992).

Rapeseed oil has been partially consumed by humans since the Middle Ages. However, speculations later emerged that erucic acid, present in high amounts in the oil's composition, and glucosinolates, a sulfur-rich compound group found in the meal used as animal feed after seed processing, could be harmful to human and animal health. Additionally, the phytic acid (phytin) content cannot be utilized by monogastric animals.

Breeding efforts aimed at eliminating these two risk factors yielded positive results, and the first rapeseed variety, named "Tower," was developed in Canada with reduced levels of both erucic acid and glucosinolates. These new varieties, with erucic acid content in the oil below 2% and glucosinolate content in the meal below 30 $\mu\text{mol/g}$, are generally referred to as "canola." The term "canola" has also entered the Turkish language as "kanola." The word canola is a commercial name derived from the first three letters of "Canada" combined with the initial letters of "oil," "low," and "acid." Additionally, these varieties are commonly known as "double-zero" or "çift sıfır" varieties due to their low levels of both erucic acid and glucosinolates (Sovero, 1993). In Europe, the first double-zero rapeseed varieties, "Eurol" and "Samourai," were developed between 1980 and 1990 (Despeghel, 1997).

Rapeseed was introduced to Turkey during World War II through immigrants from Bulgaria and Romania (Ögütçü & Kolsarıcı, 1979; Özgüven, 1990). Prior to 1980, it was cultivated in various regions, particularly Thrace, but its cultivation was banned for two years by the Turkish Ministry of Health due to the identification of risk factors such as erucic acid and glucosinolates (İpkin et al., 1990). The ban was lifted with the development of double-zero varieties, and on April 15, 1987, the Turkish Ministry of Health issued a report permitting the use of rapeseed oil in human food.

Rapeseed oils contain palmitic acid ranging from 0.0–0.36%, stearic acid from 0.05–0.35%, oleic acid from 72.30–83.42%, linoleic acid from 10.18–21.11%, linolenic acid from 1.23–4.07%, eicosenoic acid from 0.0–5.52%, and erucic acid from 0.0–3.01%.

Due to its high boiling point (238°C), it is an excellent frying oil. The meal remaining after rapeseed oil extraction, with its high protein content (approximately 39–40%), is incorporated into animal feed rations. Rapeseed can also be used as green fodder and silage. It is the first cultivated crop to flower in spring.

In the oil production process, sunflower and cotton seeds are first separated from their hulls, whereas rapeseed seeds are directly ground and processed. While the protein and cellulose content in sunflower seed meal and cottonseed meal vary, these ratios remain consistent in rapeseed meal. Additionally, rapeseed cultivation has lower input costs compared to many other crops.

According to 2022 global oilseed crop data, soybean leads with 133.7 million hectares, followed by rapeseed (39.9 million ha), cottonseed (31.4 million ha), peanut (30.5 million ha), palm (30.0 million ha), and sunflower (29.2 million ha) (FAOSTAT, 2024).

Based on 2023 regional data, 67.76% of rapeseed cultivation areas are located in the Marmara Region, with 59.27% of rapeseed production occurring in this region due to its cultivation area (TUIK, 2024). In recent years, Konya province has held a significant share in rapeseed cultivation and production outside the Marmara Region.

GLUCOSINOLATES

Glucosinolates are secondary plant metabolites commonly found in plants of the Brassica (Cruciferae) family, containing sulfur (S) and nitrogen (N). They are non-nutritive compounds present in rapeseed oil. These compounds consist of a β -D-thiogluco group, a sulfonated oxime group, and a side chain derived from methionine, tryptophan, or phenylalanine. Glucosinolates are water-soluble, anionic, non-volatile, and heat-resistant, exhibiting no significant biological activity unless they undergo enzymatic degradation (Fenwick et al., 1983; Fahey et al., 2001). To reduce glucosinolate hydrolysis and the solubility of sulfur in the oil, the activity of the myrosinase enzyme must be carefully controlled during heat treatment. The myrosinase enzyme becomes active within a temperature range of 50–70°C (Shahidi, 2005).

When plant tissue is cut, chopped, chewed, or otherwise damaged, glucosinolates are hydrolyzed by the endogenous myrosinase enzyme (thioglucoside glucohydrolase, E.C. 3.2.3.1) naturally present in the plant. This process results in the release of various aroma compounds, such as thiols, depending on environmental conditions (e.g., pH, temperature, humidity, and storage conditions).

Sulfur-containing glucosinolates in rapeseed oil are degradation products and are organic compounds. These sulfur components also enhance the stability of the oil. Certain components exhibit antioxidant behavior, protecting the oil from oxidation. Other beneficial effects of these components include inactivating substances, such as metals, that act as catalysts during oxidation (Shahidi, 2005).

The degradation products of glucosinolates are soluble in oil, volatile, highly reactive, and possess a sharp odor and taste profile. Additionally, some exhibit fungicidal, bactericidal, antiprotozoal, nematicidal, and allelopathic effects, playing significant roles in biological processes (Chew, 1988; Lazzeri et al., 1993; Palada, 1996; Charron & Sams, 1999). To date, approximately 120 different glucosinolates have been identified in about 450 species across 16 plant families (Cole, 1976; Fenwick et al., 1983; McGregor et al., 1983; Mithen et al., 2000; Fahey et al., 2001).

Environmental factors are among the key determinants of glucosinolate content. It has been found that glucosinolate levels in black mustard and rapeseed decrease with increased nitrate application (Fenwick et al., 1983). Irrigation regimes also influence glucosinolate content. Glucosinolates are reported to provide significant protection against diseases and pests (Harbone, 1998). Furthermore, sulfur and nitrogen fertilization not only increase yield and protein content but also lead to an increase in glucosinolate levels (Cramer, 1990; Türk et al., 2008).

The glucosinolate content in rapeseed meal is desired to be below 30 $\mu\text{mol/g}$. Numerous studies based on feeding experiments with rapeseed have investigated the physiological effects of glucosinolates and their hydrolysis products. These studies have observed enlargement of the thyroid, adrenal glands, kidneys, and liver, and liver hemorrhage (Liver Hemorrhage Syndrome - LHS) has been identified in poultry fed with rapeseed meal. Nishie and Daxenbichler investigated the toxicological effects of three glucosinolates and nine degradation products on mice. None of these compounds were found to be teratogenic, but 2-propenyl isothiocyanate,

3-methylsulfinylpropyl isothiocyanate, and 1-cyano-3,4-epithiobutane were observed to be embryotoxic. It has been established that many naturally occurring isothiocyanates are cytotoxic. Isothiocyanates formed from glucosinolates are highly unstable and spontaneously degrade into various molecules. One such degradation product, oxazolidine-2-thione, has been reported to cause thyroid gland enlargement and goiter in rabbits (Fahey et al., 2001).

Despite being an oil-rich seed, rapeseed is also a significant source of protein, and its glucosinolate content is a critical factor in its use for animal feed. These compounds can indirectly transfer to humans through the milk of animals fed with plants from this group. The total glucosinolate content in canola meal is approximately $7.2 \mu\text{mol g}^{-1}$ (Newkirk et al., 2003). Canola hay, silage, and straw can accumulate sulfur (S) at levels as high as 0.5–1.3% of dry matter (DM). To prevent hemolytic anemia caused by S-methyl-L-cysteine sulfoxide, which manifests as symptoms such as blood in urine and weakness; to avoid polioencephalomalacia (PEM) caused by reduced thiamine (vitamin B1) absorption leading to brain necrosis; to prevent elevated hydrogen sulfide levels in the rumen; to ensure proper absorption of copper (Cu) and selenium (Se); and to avoid goiter caused by isothiocyanates, the sulfur content in daily ruminant rations should generally not exceed 0.4% of DM. It is recommended that canola hay does not exceed 50–60% of the dry matter in Total Mixed Rations (TMR) for dairy cows and feedlot cattle. For example, if 14 kg/day of roughage is used in a standard diet, 6 kg could be canola hay and 8 kg could be alfalfa hay (Lardy et al., 2015; Llewellyn, 2018; Vitti, 2018). The most distinctive characteristic of sulfur-containing compounds is their strong and characteristic aroma, which can be detected even at very low concentrations.

To prevent excessive formation of sulfur and other anti-nutritional compounds in canola, it is recommended to avoid over-application of nitrogen (N) and sulfur (S) fertilizers, maintain an N:S ratio of 5:1 in the plant, allow at least 45 days for silage maturation, dilute high levels of N and S with other roughages after analysis, and, where possible, practice intercropping with peas or produce mixed silage (Llewellyn, 2018).

ERUCIC ACID

Erucic acid (cis13-docosenoic acid) is a long-chain monounsaturated fatty acid (C22:1) with 22 carbon atoms and no branching, and it has a double bond in the omega-9 position. It is found in the seeds of plants belonging to the Cruciferae and Tropaeoleaceae families, and its proportion in rapeseed oil varies between 30% and 60% (Roine et al., 1960).

The first low-erucic acid rapeseed (DEAK) of the *B. napus* species was developed in 1968, and the first low-erucic acid rapeseed of the *B. rapa* species was developed in 1971 in Canada. Rapeseed is classified based on its erucic acid content: High Erucic Acid Rapeseed (HEAR) contains 45-60% erucic acid (HEAR: High Erucic Acid Rapeseed), varieties with medium levels of erucic acid (35-40%), and varieties with erucic acid reduced to as low as 0.03%, classified as Low Erucic Acid Rapeseed (LEAR: Low Erucic Acid Rapeseed). Rapeseed should contain less than 2% erucic acid. Rapeseed oil produced in Asia contains 22-60% erucic acid. The decrease in erucic acid content in rapeseed oil has led to a significant increase in oleic acid content, as well as a slight increase in linoleic and linolenic acid content.

The idea that erucic acid might have toxic effects was first suggested by Roine et al. (1960). Subsequent studies in mice showed that triglycerides, largely composed of erucic acid and accumulating in heart muscles, somehow negatively affect the oxidation of fatty acids in mitochondria and ATP production, reducing the contraction strength of heart muscles and causing a disease called myocardial lipidosis (Abdellatif and Vles, 1970; Houtsmuller et al., 1970; Sauer and Kramer, 1983; Anonymous, 2025a). Although no data has been found to date showing that erucic acid is harmful to human health, it is still considered a risk factor. Rapeseed oil, which has negative effects on heart diseases, can cause side effects such as anemia,

constipation, vision damage, and hypersensitivity when consumed excessively. Permanent damage to the kidneys and adrenal glands is also among the harms of rapeseed oil.

Due to the erucic acid it contains, rapeseed oil has negative effects on the immune system, and excessive consumption can cause damage to the circulatory and nervous systems. One of its greatest dangers is that it increases the risk of lung cancer.

One of the underlying reasons for the harms of rapeseed oil is the amount of trans fat it contains. The use of rapeseed oil in margarines further increases the risks associated with trans fat.

PHYTIN (PHYTIC ACID-PHYTATE)

Rapeseed contains phytic acid. Phytic acid is the storage form of phosphorus in plants. Phytates are the Ca, Mg, K, and Fe salts of phytic acid. They affect the bioavailability of minerals. Non-ruminant animals cannot separate phosphorus from phytic acid due to the absence of phytase enzyme. 50-85% of phosphorus in plants is in the form of phytic acid. They are commonly found at varying levels (0.1-6%) in plant seeds, grain feeds, roots, and tubers. In ruminants, due to microbial phytase, ruminants can utilize phosphorus from phytate. A large portion of poultry compound feeds consists of grain feeds and meals, and most of the phosphorus in these feed materials is in the form of phytin phosphorus. Since enzymes that break down phytic acid are produced in very small amounts or not at all, phosphorus from phytate cannot be utilized, and 70% of phosphorus in feeds is excreted in feces. Additionally, phytate can indirectly bind Ca, Zn, and Mn, causing deficiencies of these minerals. As a solution, phytase enzyme should be added to the ration (Yalçın, 2002). In rapeseed, total P content is 12.4 g/kg, Phytin-P content is 2.1 g/kg, and Phytin-P percentage is 16% (Sarıfakıoğulları and Önel, 1998).

NITRATE

Nitrogen (N) is one of the essential macro nutrients that affects crop growth, development, yield, and quality (Koch et al., 2020; Kumar et al., 2021). Plants utilize various N forms in soils. Nitrate (NO_3^-) and ammonium (NH_4^+) ions are the N forms preferentially absorbed by plants from the growing medium (O'Brien et al., 2016; Cui et al., 2017). Nitrate, due to its wide distribution in soil and high solubility in water, is most likely one of the most widespread pollutant ions worldwide and has a negative impact on the quality of water resources and agricultural products (Zendehbad et al., 2022).

Many nutrients such as chloride, calcium, potassium, sulfate, and phosphorus are involved in the NO_3^- accumulation process in plants. Nitrate content varies according to different parts of the plant and the age of the plant (Santamaria et al., 1999; Anjana et al., 2006). NO_3^- uptake mostly occurs in roots, but the contribution of leaves should not be overlooked (Anjana and Iqbal, 2007). NO_3^- absorbed through leaves is initially stored in vacuoles and then transported from old leaves to young leaves depending on the NO_3^- requirement of the leaves (Le Deunff et al., 2019). Maynard et al. (1976) reported that NO_3^- concentration is at the lowest levels in the flowering parts of the plant; in contrast, nitrate is found in increasing concentrations in fruits or grains, leaves, roots, petioles, or stems.

Nitrate is necessary for plant growth and development. However, very high NO_3^- concentrations in cell sap can be harmful to plants (Yosoff et al., 2015). As a result of nitrogen fertilizer application without considering the actual needs of the plant and the amount of N available in the soil, NO_3^- accumulation may occur due to excessive N uptake by the plant (Özenç and Şenlikoğlu, 2017).

NO_3^- accumulation is generally dependent on the amount and type of nutrients present in the soil, but is also closely related to application timing, the amount and composition of applied fertilizers (Zhou et al., 2000). Nitrate accumulation is one of the major disadvantages of high-

level fertilizer application in rapeseed (Chakwizira et al., 2015). The use of fertilizers based on ammonia or nitrate-ammonium mixtures can reduce NO_3^- content in plants (İnal and Tarakçıoğlu, 2001; Santamaria et al., 2001). Increased potassium application rates facilitate nitrate uptake and transport to above-ground parts of the plant, as well as promote nitrate metabolism and utilization, consequently reducing NO_3^- accumulation in some vegetable plants (Ahmed et al., 2000; Ruiz and Romero, 2002). However, some studies have shown that potassium sources in soil do not affect NO_3^- accumulation (Drlik and Rogl, 1992).

In a study conducted by Grzebelus and Baranski (2001), the effect of climate on NO_3^- accumulation was examined, and it was determined that NO_3^- content was lower in years with high precipitation. In hot and rainy years, increased NO_3^- accumulation is possible regardless of whether nitrogen comes from organic or mineral sources (Custic et al., 2003). However, NO_3^- accumulation also varies according to season (Vieira et al., 1998). NO_3^- accumulation levels are higher in autumn-winter months compared to spring (Santamaria et al., 1999). It is thought that in winter, plants cannot utilize all the nitrogen available in the soil due to lower light and temperature conditions (Anjana and Iqbal, 2007).

When saliva is swallowed and encounters acidic gastric juice, it converts to nitrosating species (N_2O_3 and NOSCN) and reacts with ascorbic acid in gastric juice to form nitric oxide (NO), which is potentially mutagenic and carcinogenic (Moriya et al., 2002; Iijima et al., 2003; McColl, 2005). Excessive local production of nitric oxide has been reported to lead to functional abnormalities associated with reflux diseases (McColl, 2005). Additionally, high nitrite oxide levels have been suggested to be associated with various skin problems such as psoriasis, dermatitis, and even skin cancers (Karwowska, 2020).

High NO_3^- intake has been reported to increase the risks of bladder (Michaud et al., 2004), esophageal, nasopharyngeal, and prostate cancers (Eicholzer and Gutzwiller, 1990). Other health problems associated with nitrate toxicity include oral cancer (Badawi et al., 1998), colon, rectum, or other gastrointestinal region cancers (Knekt et al., 1999; Türkdoğan et al., 2003), Alzheimer's disease, vascular Biswaner type or multiple small infarct type dementia (Tohgi et al., 1998), multiple sclerosis (Giovannoni et al., 1997), spontaneous abortion or congenital defects (Fewtrell, 2004), anencephaly (Croen et al., 2001), non-Hodgkin lymphoma (Michal, 1998), and cardiovascular disorders (Morton, 1971).

ABSTRACT

Black mulberry (*Morus nigra* L.) was used in this study as a natural source of polyphenol oxidase (PPO). It is known for its high lycopene content and antioxidant activity. The enzyme was extracted by mixing the fruit with a solution containing 0.1 M sodium phosphate buffer (pH 7.0), 0.5% PEG 6000, 10 mM ascorbic acid and 50 mM K₂HPO₄. This resulted in a PPO activity of 3753 U/mL. We treated the enzyme after extraction with different organic solvents (DMSO, ethanol, isopropanol and methanol) and surfactants (SDS, Triton X-100, Tween-20 and Tween-80) to see how stable and active it was. Isopropanol and methanol were the best solvents for restoring activity, while Tween-80 had the same effect as the surfactants. These results show that PPO from the black mulberry tree can handle many organic solvents and surfactants, making it a good candidate for use as a strong biocatalyst in industry, especially in systems that do not contain water or surfactants.

Keywords: *Morus nigra* L., polyphenol oxidase, organic solvent, surfactant, enzyme activity

INTRODUCTION

The black mulberry is a plant that belongs to the mulberry family (Moraceae). The mulberry is native to India and Japan. It grows in temperate and subtropical climate regions (Özelçi and Yiğit 2022). It has an oval-cylindrical shape with flattened ends and its fruits are black-purple, fleshy-juicy and have a sour taste (Özkaya Erkaleli and Dalkılıç, 2016). Anthocyanins, phenolic compounds and potassium are found in large quantities in black mulberries (Aşkın et al., 2022). As it contains flavonoids, it has anti-cancer, anti-tumor, anti-radiation, anti-inflammatory and antimicrobial effects. It is also a medicinal plant that can help with coughs, urinary urgency, high blood sugar and vomiting (Feng et al., 2015). According to studies, black mulberry medicines relieve tonsillitis and are good for mouth and tooth wounds (Aşkın et al., 2022). It is eaten fresh and dried. It is used in the production of foods such as molasses, fruit juice, jam and pestle (Sernikli and Kadakal, 2020).

Polyphenol oxidase (PPO; EC 1.14.18.1) is a metalloenzyme that converts phenolic compounds into o-quinone derivatives that cause enzymatic browning of fruits and vegetables. In the food industry, PPO is considered an important biocatalyst for quality control, the development of biosensors and the management of enzymatic browning in the processing of fruits and vegetables (Tilley et al., 2023; Almeida and Nogueira, 1995). However, as the

stability and activity of PPO are sensitive to environmental conditions, its use in industry may be limited (Zou et al., 2025).

The effects of organic solvents and surfactants on PPO activity are important for industrial applications. Organic solvents can increase catalytic activity by facilitating the enzyme's access to the substrate. However, at high concentrations, they can also disrupt the conformation of the enzyme and lead to inhibition (Salehi et al., 2021). Similarly, ionic and non-ionic surfactants can modulate the activity of PPO by interfering with hydrogen bonds, electrostatic interactions or hydrophobic regions on the enzyme surface (Yang et al., 2007). These effects depend on factors such as the type of surfactant, its concentration and the pH of the medium (Aguirre-Ramírez, 2021).

In this study, the effects of different organic solvents (isopropanol, methanol, ethanol, dimethyl sulfoxide) and commonly used surfactants (SDS, Triton X-100, Tween-20, Tween-80) on PPO activity were comparatively analyzed; the data obtained were evaluated regarding the stability of the enzyme. The knowledge gained will support the use of PPO in durable systems for industrial applications such as food, cosmetics and pharmaceuticals.

MATERIAL AND METHOD

The samples of black mulberries were bought at markets in the province of Kocaeli. The commonly used parts of the black mulberry samples were washed and stored at -80 °C. Fresh black mulberry samples were weighed to 200 g, homogenized and pureed with a blender. 15 g of the pureed fruits were weighed and placed separately in Falcon tubes. 15 mL of 0.1 M sodium phosphate buffer (pH 7.0) was added. The extraction process was then carried out using separate extraction media.

The chemicals used to increase the extraction efficiency were polyvinylpolypyrrolidone (PVPP) (%1, w/v), ascorbic acid (10 mM), Triton X-100 (%1, v/v), phenylmethylsulfonyl fluoride (PMSF) (2 mM), polyethylene glycol (PEG6000, 0.5%, w/v) and K₂HPO₄ (50 mM). PVPP and ascorbic acid were used to remove or reduce phenolic compounds in the medium, while Triton X-100 was added to the mixture during extraction to solubilize the enzyme bound to the membrane. PMSF was preferred to increase enzyme activity, while PEG 6000 was used to remove phenols that could inhibit PPO (Erzengin, 2009; Gauillard and Rich-Forget 1997; Palma-Orozco et al., 2011). The prepared solution was shaken for 1 min. The resulting homogenate was kept at 4 °C for 20 min and then centrifuged at 10000 x g for 30 min in the cold. After centrifugation, the mixture was filtered and the pellet at the bottom was removed, while the crude enzyme extract was recovered from the upper aqueous phase (Navarro et al., 2014).

To detect the presence of the PPO enzyme, the increase in absorbance was measured at 420 nm (24 °C) using a spectrophotometer (Cary 60, Agilent). To measure the enzyme activity, a sample cuvette was prepared by adding 200 µL of the enzyme suspension to the substrate solution (catechol) prepared in 2800 µL sodium phosphate buffer (100 mM, pH 7.0). The control cuvette was prepared in the same way, but without enzyme. The enzyme solution was prepared with 100 mM sodium phosphate buffer solution (pH 7.0) (Erzengin, 2009). One enzyme unit is the amount of enzyme that catalyzes the formation of 1 µmole of quinone in one minute at room temperature. The Bradford method was used to determine the amount of protein in the samples. The amount of protein in the samples was measured at 595 nm using the spectrophotometric method (Bradford, 1976).

In stability tests performed to investigate the effects of organic solvents and surfactants on PPO activity, the activity was determined using chloroform, isopropanol, ethanol and dimethyl sulfoxide as organic solvents and SDS, Triton X-100, Tween-20 and Tween-80 as surfactants. The organic solvents were analyzed in the concentration ranges of 5-10-30-60%

and the surfactants in the value ranges of 0.1 and 1 mM. After 30 min of pre-incubation, the PPO activity was measured at a temperature value and the remaining activity was calculated according to the following formula (İllensanmi et al., 2023; Birge et al., 2022; Šalić et al. 2018).

% Residual activity = $[100 - (\text{polyphenol oxidase activity after treatment}) / (\text{polyphenol oxidase activity before treatment})] \times 100$

RESULTS AND DISCUSSION

The polyphenol oxidase (PPO) activity of mulberry fruit was analyzed in a crude extract prepared with an extraction medium containing 50 mM K₂HPO₄, 0.5% PEG 6000, 10 mM ascorbic acid and 0.1 M sodium phosphate buffer (pH 7.0). The PPO activity under these conditions was determined to be 3753 U/mL. Comparable extraction techniques and activity values have been documented in the literature for different plant species. For example, Erzengin (2002) used 0.5 M sodium phosphate buffer (pH 7.3), 0.5% PEG 6000, 10 mM ascorbic acid and 50 mM K₂HPO₄ to analyze white mulberry (*Morus alba* L.). An extraction medium containing 0.5 M sodium phosphate buffer (pH 7.3) and 0.5% PEG yielded a PPO activity of 567 U/mL in another study on Iğdır apricots (*Prunus armeniaca* L.) (Demir et al., 2012). Ziyen and Pekyardımcı (2003) used 50 mM ascorbic acid, 10% PEG and 0.2 M phosphate buffer (pH 7.2) for Jerusalem artichoke (*Helianthus tuberosus*). Similarly, the extraction medium for the borago (*Trachystemon orientalis*) study by Alici and Arabacı (2016) contained 0.1 M phosphate buffer (pH 7.0), 1 mM ascorbic acid, 0.5% PVPP and 2% Triton X-100. Ascorbic acid and PVPP are commonly used in most extraction procedures to remove phenolic compounds from the medium. PEG 6000 helps to maintain enzyme stability by binding phenolic compounds that could inactivate PPO, Triton X-100 helps to release membrane-bound enzymes and PMSF helps to maintain enzyme activity (Gauillard and Richard-Forget, 1997; Erzengin, 2009; Palma-Orozco et al., 2011).

To determine the effects of organic solvents and surfactants on the activity of polyphenol oxidase (PPO) extracted from mulberries, experiments were carried out at different concentrations. The organic solvents were used at concentrations of 5%, 10% and 30%, including DMSO, ethyl alcohol, isopropanol and methanol. The surfactants used were SDS, Triton X-100, Tween-20 and Tween-80 at concentrations of 0.1 mM and 1 mM.

The effects of organic solvents on PPO activity are shown in Figure 1. The recoveries of PPO activity were as follows: in the presence of DMSO 77%, 108% and 10%; ethyl alcohol 52%, 114% and 82%; isopropanol 158%, 151% and 124%; and methanol 93%, 161% and 104% at a concentration of 5%, 10% and 30%, respectively. It is noteworthy that all solvents led to a significant increase in PPO activity at certain concentrations. The highest activity recovery was observed at 10% for DMSO, ethyl alcohol and methanol and at 5% for isopropanol. These results indicate that PPO extracted from mulberries has a remarkably high resistance to organic solvents.

Figure 1. Effect of organic solvents (a-d) on black mulberry polyphenol oxidase enzyme activity

The effects of SDS, Triton X-100, Tween-20 and Tween-80 on PPO activity are shown in Figure 2. At concentrations of 0.1 mM and 1 mM, the recoveries of PPO activity were 57% and 52% for SDS, 74% and 35% for Triton X-100, 78% and 74% for Tween-20, and 92% and 79% for Tween-80. Both Tween-80 and Tween-20 showed high activity recovery at both concentrations. Tween-80 showed remarkable recoveries of 92% at 0.1 mM and 79% at 1 mM. In the presence of SDS, activity recovery was above 50% at both concentrations, while the recovery of 74% observed with Triton X-100 at 0.1 mM also represents a remarkably high level of activity.

Figure 2. Effect of surfactants (a-d) on black mulberry polyphenol oxidase enzyme activity

The effect of organic solvents and surfactants on enzyme activity is a complex interaction determined by changes in the enzyme microenvironment, substrate solubility and structural integrity of the protein. Organic solvents can increase enzyme activity by increasing the solubility of hydrophobic substrates and shifting the reaction equilibrium from hydrolysis to synthesis (Samiey et al., 2014). However, they often lead to reduced enzyme dynamics, changes in active site polarity and even partial denaturation, especially with prolonged exposure, resulting in reduced catalytic efficiency and stability (Zhao, 2020). On the other hand, surfactants can modulate enzyme activity through direct interactions with the enzyme surface. Especially with hydrophobic substrates, they can cause limited conformational changes that expose the active site or improve the accessibility of the substrate and thus increase activity (Savelli et al., 2000). In some cases, surfactants such as SDS facilitate substrate access to the active site and activate the enzyme, but at higher concentrations they can destabilize the protein and cause denaturation. Crystallographic studies confirm that surfactants can have pronounced effects on enzyme conformation, which can either promote or inhibit enzymatic activity depending on the enzyme and surfactant type (Goldfeder and Fishman, 2014).

CONCLUSIONS

In this study, the PPO activity of mulberry fruit was calculated at 3753 U/mL in the crude extract obtained with an extraction medium containing 0.1 M sodium phosphate buffer (pH 7.0), 0.5% PEG 6000, 10 mM ascorbic acid and 50 mM K₂HPO₄. In the experiments performed to evaluate the effects of organic solvents on enzyme activity, the mulberry PPO enzyme showed the highest activity recovery at concentrations of 5% isopropanol, 10% methanol and 30% isopropanol. As for surfactants, the highest recovery was observed with Tween-80 at concentrations of 0.1 mM and 1 mM.

ABSTRACT

Persimmon (*Diospyros kaki* L.), originally from China and widely cultivated throughout East Asia, has recently gained popularity in several Mediterranean countries, including Türkiye. This study was conducted to determine the optimum harvest time by evaluating the biochemical and aromatic changes in persimmons at different maturity stages. The research was carried out in a commercial orchard in the Dareski hamlet of the Toroslar district, Mersin Province, focusing on the commonly grown 'Hachia' cultivar. Fruits were harvested at seven-day intervals beginning in the last week of October and analyzed at two distinct maturity stages: unripe and fully ripe. Sugar analysis revealed that glucose and fructose were the predominant sugars in both stages, with significantly higher levels in ripe fruits (8930 and 9166 mg/100g, respectively) compared to unripe ones (6561 and 7213 mg/100g). Total sugar content increased from 13,867 to 18,248 mg/100g, along with an increase in total soluble solid content (TSS) from 14.45% to 19.4%. In terms of organic acids, malic acid was dominant in unripe fruits (22.43 mg/100g), whereas succinic acid significantly increased in ripe fruits (38.27 mg/100g). Citric and ascorbic acid contents also varied notably between the two stages, and titratable acidity rose from 0.86% to 1.14% during ripening. Volatile compound profiling revealed clear maturity-dependent differences. Aldehyde compounds were more abundant in ripe fruits (37.76%), contributing to a richer and more intense aroma, while alcohols and terpenes predominated in unripe fruits (17.44% and 44.98%, respectively), with linalool, nerol, and limonene as major contributors. These findings confirm that the biochemical and aromatic profiles of persimmons are strongly influenced by the maturity stage, which has important implications for flavor development, postharvest quality, and market value. Despite increasing interest among consumers and producers, persimmon production in Türkiye is still limited due to challenges in storage and marketing. The study suggests that harvesting after the second ripening stage may improve product quality and commercial potential under the Mediterranean climate of Mersin.

Keywords: Persimmon, maturity stage, sugars, organic acids, volatile compounds.

INTRODUCTION

Fruit cultivation worldwide is generally concentrated on a limited number of species; however, persimmon (*Diospyros kaki* L.), belonging to the Ebenaceae family, has gradually expanded to many regions of the world and has gained increasing popularity in recent decades (Öz and Özelkök, 2003). Native to China, persimmon was first extensively cultivated in Japan and later established in modern orchards in countries such as the United States (California), Italy, Brazil, New Zealand, Australia, and Israel (Kaynaş & Kuzucu, 2004). The fruit, known for its attractive appearance and pleasant taste, has been given names such as “Japanese persimmon,” “Mediterranean persimmon,” and “cennet hurması” in Turkey (Yıldız Akbulut, 2021). Although the genus *Diospyros* contains numerous species, only four (*D. kaki* Thunb., *D.*

lotus L., *D. virginiana* L., and *D. oleifera* Cheng) are of commercial importance, with *D. kaki* being the most widely cultivated for fresh consumption and processing (Kitagawa & Glucina, 1984; Yıldız et al., 2012). In Turkey, persimmon production has expanded considerably in the last 20–25 years. While production levels were between 15,000–20,000 tons in the early 2000s, it increased to 127,314 tons in 2023 and reached 142,584 tons in 2024, showing a 12% growth within a year (Anonymous, 2025a). This rise reflects both consumer demand and the fruit's adaptation to different climatic regions of Türkiye, including the Mediterranean, Aegean, Marmara, and Black Sea. Persimmons are harvested between September and December, displaying wide variation in fruit shape, size, and skin color. Both astringent and non-astringent cultivars are cultivated; while astringent fruits are unpleasantly bitter when unripe due to soluble tannins, they become sweet and palatable after softening or through specific postharvest treatments (Onur, 1990).

The ripening of persimmon fruit is a complex process involving physiological, biochemical, and structural changes. These changes affect sensory attributes such as color, taste, and texture, determining overall fruit quality (Chitarra et al., 2005). During maturation, chlorophyll degradation and carotenoid accumulation cause color changes from green to yellow, orange, or reddish hues (Kluge et al., 2018; Zhao et al., 2011). Studies have shown that carotenoid content, including lycopene, increases markedly during the mid to late stages of ripening, contributing to the reddish coloration of certain cultivars (Qi et al., 2019). Texture softening is mainly attributed to pectin degradation, cell wall disintegration, and membrane breakdown, while increased intercellular spaces and water loss lead to fruit weight reduction (Salvador et al., 2007; Tessmer et al., 2016; Sapper et al., 2019). Carbohydrate metabolism plays a key role in fruit ripening and sweetness perception. Changes in sugar composition are largely influenced by cultivar-specific enzymatic activity. In general, sucrose content decreases while glucose and fructose increase during ripening due to invertase activity (Bubba et al., 2009; Giordani et al., 2011; Santos et al., 2019). Different developmental patterns have been reported, such as sucrose reduction accompanied by increases in glucose and fructose or stability in certain sugars depending on the cultivar (Santos et al., 2018). Alongside carbohydrates, organic acids, amino acids, phenolics, and choline also undergo significant changes during maturation, especially in the late stages of development (Santos et al., 2018). Nutritionally, persimmon is an important source of ascorbic acid, carotenoids, phenolic compounds, and dietary fiber, contributing to high antioxidant activity and health-promoting effects (Parseker Yönel et al., 2008). Vitamins A and E, tannins, and minerals also enhance its nutritional and functional food value. These properties have contributed to growing consumer demand worldwide. However, challenges such as cultivar identification, determination of optimum harvest time, and effective postharvest handling still cause yield and quality losses (Onur, 1990; Tuzcu & Yıldırım, 2000). A major quality determinant is astringency, resulting from soluble tannins, which decrease during ripening due to polymerization or can be artificially reduced through treatments such as ethylene exposure, CO₂ application, or storage in alkaline solutions (Ito, 1971; Ito, 1980; Taira et al., 1997). Considering its nutritional richness, consumer preference, and economic potential, persimmon has become an increasingly valuable fruit crop in Turkey. Nevertheless, studies on its phytochemical and volatile composition under local ecological conditions are still limited. Therefore, this study focuses on the characterization of phytochemical compounds and volatile profiles of the 'Hachiya' persimmon cultivar grown under the ecological conditions of Mersin (Toroslar, Türkiye). The results are expected to provide new insights into ripening behavior, postharvest quality, and flavor development, ultimately contributing to reducing postharvest losses and increasing consumer acceptance.

MATERIALS AND METHODS

Plant Material

Persimmon fruit samples were collected from 20-year-old Hachiya trees planted in 5x5 spacings at various stages of ripening in a producer garden in Darseki village, Toroslar district, Mersin province. The samples were collected twice in 2023, once in October (unripe period) and once in November (ripe period). Fruit samples from three distinct trees and five fruit samples from different sides of the tree (North, South, West, and East) were taken in three repetitions during each harvest period and brought to the Horticulture laboratory of Çukurova University Faculty of Agriculture in an ice box cold chain. After washing the samples in tap water, 1 gram of hand squeezed fresh fruit juice was utilized for each biochemical assay.

Method

Total Soluble Solids (TSS): The SSC of representative fruit samples was measured as °Brix using a digital refractometer (Atago, Japan). A drop of fruit juice was placed on the screen, and the displayed value was recorded as % SSC.

Titrateable acidity (TA): A 1 ml sample of fruit juice was titrated with 0.1 N NaOH solution until the pH reached 8.1. The acidity was expressed as a percentage of malic acid (Cemeroğlu 2007).

Individual Sugar and Organic Acid Extraction and Determination

Sugars and organic acids were extracted individually following the procedure described by Mikulic-Petkovsek et al. (2016). Homogenized, unfrozen fruit samples were placed in a test tube containing 4 mL of bi-distilled water, at 1 g. The mixture was continuously mixed on a vortex mixer at room temperature for thirty minutes. After extraction, the samples were centrifuged at 9000 x g for ten minutes at 4°C to obtain the supernatant and then filtered into vials using cellulose membranes. The extracts were stored at -20°C for further investigation. The high-performance liquid chromatography (HPLC) system was equipped with a refractive index detector (Shimadzu RID 20A VP, Kyoto, Japan), an in-line degasser, a pump, a controller, and a 20 µL injection volume automatic injector. Chromatographic separation was performed using a reverse-phase Ultrasphere Coregel-87 C analytical column (300 mm × 7.8 mm i.d., 5 µm, Transgenomic) at a flow rate of 0.6 mL/min, heated to 70 °C, and with the mobile phase being ultrapure water. Data acquisition and processing were performed with Shimadzu Class VP chromatography management software (Kyoto, Japan). Concentrations of individual sugars are reported as percentages of fresh weight (FW) determined using original standards.

Volatile compounds were extracted by solid-phase microextraction (SPME)

Volatile compounds obtained from avocado seeds were studied using three randomly selected fruits at each stage, both unripe and commercially ripe. For each case, 1 gram of homogenized seed tissue was placed in a headspace vial, and then 1 mL of CaCl₂ was added. Following a 30-minute 40 °C treatment, the volatile components were extracted using a solid-phase microextraction (SPME) fiber coated with CAR/PDMS (blue fiber). Using the method detailed by Polat and colleagues (2022), the obtained aroma compounds were then analyzed and quantified using a Shimadzu GC-2010 Plus gas chromatography-mass spectrometry (GC/MS) system.).

Statistical Analyses

The experiment was performed with a completely randomised experimental block design in three replications two stages (unripe, ripe) in each replicate. Data were processed with the SPSS package program version 23.0 (SPSS Inc., Chicago, IL, USA). All data were presented as the

mean $\pm$ standard error (SE) and analyzed by one-way analysis of variance (ANOVA). (Steel, et al 1997).

RESULT AND DISCUSSION

Sugars are also related to the total soluble solids (TSS) content. In persimmon, this characteristic ranges from 12 to 22 °Brix, due to the great differences between cultivars, maturation, and postharvest treatments, which influence both the content and the profile of these compounds (Kluge et al., 2018). It is important to highlight that the presence of soluble tannins also influence the TSS content. Kim and Ko (1997) observed that astringent fruits with higher levels of soluble tannins presented more TSS than non-astringent cultivars did. When these soluble tannins are no longer present (after a precipitation treatment), the TSS content is affected and there is no clear difference between astringent and non-astringent cultivar types. Therefore, Tessmer et al (2016) suggest that TSS measurement should be used to identify the sugars level only in non-astringent cultivars.

At the ripe stage, the TSS (Total Soluble Solids) value was 19.4% and the titratable acidity was 1.14%, whereas at the unripe stage, the TSS value was 14.45% and the titratable acidity was 0.86% (Table 1; Figure 1). This characteristic positively reflects on the storage period by prolonging the fruit's shelf life. Accordingly, for fruits intended to be stored for longer durations, early harvests, especially those performed in November, are expected to provide significant advantages in terms of storage longevity. When previous studies are examined, it is evident that total soluble solids content (TSS) and titratable acidity (TA) values vary significantly depending on harvest time, cultivar, and ecological conditions. Özkan and Can (2013), in their study on the 'Hachiya' cultivar in Alaşehir (Manisa), reported TSS values of 14.47%, 18.06%, and 20.80% at the first, fourth, and sixth harvests, respectively. In the same study, TA values were determined as 0.19%, 0.16%, and 0.10% at the corresponding harvest times. Similarly, Kaynaş and Kuzucu (2004) reported SSC values of 23.84%, 23.65%, 22.65%, 22.75%, and 22.46% in persimmons harvested at five different times in the Çanakkale region. Yılmaz and Şeker (2024) found that SSC values ranged between 13.62% and 17.67%, being directly associated with harvest time. They noted that cultivars with astringent flesh generally had higher SSC values, such as 17.67% in 'Hachiya' and 15.72% in 'Rojo Brillante'. According to Mowat and Chee (2011), persimmons intended for export in New Zealand must meet industry class standards of an average SSC of 14% at harvest, with a minimum of 12%. In another study, Kılıç et al., (2022) reported SSC values between 18.05% and 20.63% in 'Hachiya', 'Rojo Brillante', 'Hana Fuyu', and 'Fuyu' cultivars grown in Denizli ecological conditions. TA values in the same study were determined to range between 0.14% and 0.28%. Üstün et al., (2017) also investigated different persimmon types and reported SSC values of 14.0–18.9%, total sugars of 12.3–17.1 mg/100 g, reducing sugars of 10.3–16.5 mg/100 g, sucrose of 0.38–1.90 mg/100 g, TA of 0.06–0.14%, and L-ascorbic acid content of 6.8–19.65 mg/100 g. In the study, the SSC was determined as 19.4% and the TA as 1.14% at the ripe stage, whereas at the unripe stage, the SSC was 14.45% and the TA was 0.86%. These findings are consistent with the results reported by Özkan and Can (2013), Yılmaz and Şeker (2013), Kaynaş and Kuzucu (2004), and Kılıç et al., (2022).

Table 1. TSS (Total Soluble Solids) value was 19.4% and the titratable acidity

	ripe persimmon	unripe persimmon
Total soluble solids	19.4 $\pm$ 0.10	14.45 $\pm$ 0.05
Titratable acidity	1.14 $\pm$ 0.04	0.86 $\pm$ 0.01

Figure 1. Contents total soluble solids (TSS) and titrateable acidity (TA) of persimmon fruit

Sugars

In study, four sugars glucose, fructose, sucrose, and xylose were analyzed and measured for each cultivar (Table 2). Glucose was identified as the predominant sugar, followed by fructose, sucrose, and xylose. As the fruit ripened, starch was enzymatically hydrolyzed into simple sugars such as glucose and fructose, leading to a noticeable increase in sugar content (Yılmaz, and Bostan 2024).

At the ripe stage, the highest level was observed in glucose (95.67 ± 0.15 mg/100 g), followed by fructose (91.66 ± 3.33 mg/100 g), sucrose (89.30 ± 2.30 mg/100 g), and xylose (55.40 ± 8.35 mg/100 g). The total sugar content at this stage was determined as 182.48 ± 7.17 mg/100 g.

At the unripe stage, glucose again showed the highest concentration (72.13 ± 0.08 mg/100 g), followed by fructose (53.42 ± 18.69 mg/100 g), sucrose (65.61 ± 0.76 mg/100 g), and xylose (38.96 ± 7.61 mg/100 g). The total sugar content in the unripe stage was found to be 138.67 ± 27.13 mg/100 g (Table 2; Figure 2). The results of the study suggest that when determining the harvest date of persimmon, it is important to consider when the fruit will be marketed after harvest. If the harvested fruits are intended for storage, the harvest should be carried out during the early stages of fruit development, which corresponds to the second week of November for the Toros region. If the fruits are to be marketed without storage, the harvest should be delayed to later stages; however, in this case, as the fruit approaches the end of the ripening process on the tree, it becomes more attractive in terms of color and taste, but also more susceptible to environmental factors, particularly bird damage. On the other hand, early autumn frosts that may occur in the region during this period can cause chilling injury in the fruits. Fruits harvested in the early stages of development (the first week of November) were found not to reach high-quality edible ripeness, and the astringency caused by tannins was not eliminated in fruits at the edible stage. Robert et al. (2010) reported glucose contents in persimmon ranging from 4.78 to 8.79 mg/100g, fructose from 3.80 to 7.78 mg/100g, and sucrose from 0.91 to 1.22 mg/100g. Similarly, Candir et al., (2009) found that, considering both individual and total sugar concentrations, the cultivar ‘Tone Wase’ had the highest glucose (8.79 mg/100g), fructose (7.78 mg/100g), and total sugar (17.8 mg/100g) contents. In a study on harvest maturity of persimmon, Gasanov et al., (1973) reported that sugar accumulation during ripening was higher in Khiakume and Tamopan cultivars compared to Tsuronoko and Zendzhimaru. They further noted that the total sugar content varied among cultivars depending on harvest stage, with the highest level found in Emon and the lowest in Tamopan. In the same study, tannin content was determined as 0.164 mg/100g in Khiakume and Zendzhimaru, and

0.083 mg/100g in Tsuronoko, Emon, and Tamopan cultivars. Glew et al., (2005) demonstrated that the major sugars accumulated in persimmon juice were fructose and glucose, which increased up to 43.55 mg/100g FW and 35.45 mg/100g FW, respectively, during ripening. Sucrose remained relatively low and declined throughout ripening. These values were slightly lower than those reported by Daood et al. (1992) for an unidentified *D. kaki* L. cultivar, which contained higher glucose (11.0 mg/100g) and fructose (10.1 mg/100g) levels. The lowest total sugar content was measured in fully ripe 'O'Gosho', 'Cal Fuyu', and 'Hana Fuyu' cultivars, averaging 10.7 mg/100g. Sweetness is clearly one of the most important internal quality attributes and a key breeding objective in persimmon cultivation. Therefore, promoting cultivars with higher sugar contents is strongly emphasized. The total sugar content in persimmon is comparable to that in apples, which range between 11.5 and 18.3 mg/100g (Hofer et al., 2005). However, in apples, the predominant sugar is fructose, followed by glucose and sucrose (Veberic, Zadavec and Stampar, 2007). In persimmon cultivars with the highest total sugar concentrations, levels can reach 15–23 mg/100g, with glucose being the dominant sugar, followed by fructose and sucrose (Usenik, Fabcic and Stampar, 2008).

Table 2. Sugar content in the persimmon fruit (mg/100 g)

Sugars	Ripe persimmon	Unripe persimmon
Xylose	55.40±8.35	38.96±7.61
Sucrose	89.30±2.30	65.61±0.76
Glucose	95.67±0.15	72.13±0.08
Fruktose	91.66±3.33	53.42±18.69
Total Sugar	182.48±7.17	138.67±27.13

Figure 2. Sugar content in the persimmon fruit

The glucose and fructose levels determined in our study, when compared with the ranges reported by Robert et al., (2010) and Candir et al., (2009) (glucose: 4.78–8.79 mg/100g; fructose: 3.80–7.78 mg/100g), were found. This indicates that varietal/genotypic differences and ecological conditions play a decisive role in sugar accumulation. Our findings, compared with the 15–23 mg/100g levels reported by Gasanov et al., (1973) and Usenik et al., (2008), were at high levels. This result demonstrates that fruit ripening stage and growing conditions

have a strong effect on total sugar content. The sucrose levels obtained in our study were consistent with / deviated from the findings of Glew et al., (2005), who reported that sucrose remains relatively low and decreases during ripening. Our findings show that, in terms of sweetness and internal quality characteristics, persimmon exhibits trends similar to those reported in the literature, although differences arise depending on cultivar, growing conditions, and ripening stage. It can be concluded that genotypes with higher sugar accumulation should be preferred in cultivation.

Organic acids

Organic acids play a critical role in defining fruit taste and regulating various physiological processes, with their composition largely dependent on the cultivar. The sugar–acid balance is one of the main determinants of flavor in fruits. In addition, organic acids contribute to nutrient digestion, stimulate blood circulation, and serve as important quality indicators. Their type and concentration vary among fruit species and generally decrease as ripening progresses (Kıralan and Gündoğdu, 2021).

In study, a natural decrease in organic acid content was observed in persimmon cultivars as ripening advanced. The contents of **L-ascorbic acid, citric acid, succinic acid, and malic acid** were determined in the cultivars, and the results are summarized in Table 5. Among these, **succinic acid and malic acid were identified as the predominant organic acids.**

The sweet taste of a fruit is important for its quality and sensorial acceptance, and both primary metabolites, sugars and organic acids, play an important role. It is estimated that a higher proportion between sugars and organic acids leads to a better perception of sweet taste. (Veberic et al., 2009; Santos et al., 2017). Malic acid exerts an important influence on the sensory characteristics of persimmon (Kluge, et al 2018) and, as identified by some authors, it is one of the main organic acids in this fruit, followed by citric acid and fumaric acids (Veberic et al., 2009; Santos et al., 2017; Ryu et al., 2016).

In ripe fruits, succinic acid content was 38.27 ± 3.34 mg/100 g FW, malic acid 18.23 ± 0.50 mg/100 g FW, citric acid 11.29 ± 0.77 mg/100 g FW, and L-ascorbic acid 8.09 ± 0.45 mg/100 g FW. The total organic acid content was determined as 75.89 ± 5.35 mg/100 g (Table 3; Figure 3). In unripe fruits, higher values were recorded: succinic acid 21.37 ± 3.04 mg/100 g FW, citric acid 10.02 ± 0.16 mg/100 g FW, malic acid 22.43 ± 0.79 mg/100 g FW, and L-ascorbic acid 6.94 ± 0.67 mg/100 g FW (Table 3; Figure 3). The total organic acid content of unripe fruits was calculated as 60.77 ± 3.37 mg/100 g. The observed reduction in total acidity during fruit ripening reflects the typical metabolic changes associated with maturation (Patel et al., 2019).

Robert et al., (2010) reported that the total organic acid content was 68.1 mg/100g in the cultivar ‘Jiro’, while in the cultivars ‘Triumph’ and ‘Tipo’ it was more than twice as high, averaging 14.39 mg/100 g of organic acids. Among the organic acids analyzed, the highest malic acid content was measured in the cultivar ‘Triumph’ (10.44 mg/100 g FW), whereas the lowest value was found in ‘Jiro’ (4.01 mg/100 g FW). The malic acid levels in all analyzed cultivars were considerably lower than those reported by Daood et al., (1992), who measured 35.45 mg/100 g FW in ripe fruit of an unidentified persimmon cultivar. Compared to sweet cherry, which contains 35.30–81.20 mg/100 g FW of malic acid (Usenik et al., 2008), the fully ripe fruits of the analyzed persimmon cultivars had much lower malic acid levels. The cultivars contained between 1.96 and 7.01 mg/100 g FW of citric acid, values comparable to those obtained by Daood et al., (1992), who reported 6.57 mg/100 g citric acid in ripe persimmon fruit. In comparison with apple, which contains between 5.20 and 70 mg/100 g FW of citric acid, persimmon is lower in citric acid content. Glew et al., (2005) demonstrated that the major organic acids in date plum fruit were citric and malic acids, which increased during the immature and mid-ripe stages and then decreased in overripe fruit. According to Usenik et al.,

(2008), ripe persimmon fruit is also rich in these organic acids. However, compared with elderberry, which contains on average 30.80–48.10 mg/100 g of citric acid (Veberic, Jakopic, Stampar and Schmitzer, 2008), persimmon has a significantly lower citric acid content. In other tropical fruits, such as papaya and pineapple, the concentration of citric acid in ripe fruit is much higher (Hernández, Lobo, & González, 2008). This result is consistent with the low organic acid contents in persimmon reported by Robert et al., (2010) and Daood et al., (1992).

Table 3. Organic acids content in the persimmon fruit (mg/100 g)

	Ripe persimmon	Unripe persimmon
Citric Acid	11.29±0.77	10.02±0.16
Malic Acid	18.23±0.50	22.43±0.79
Ascorbic Acid	8.09±0.45	6.94±0.67
Succinic Acid	38.27±3.34	21.37±3.04
Total acid	75.89±5.35	60.77±3.37

Figure 3. Organic acids content in the persimmon fruit

Volatile Compounds

The volatile compounds identified in persimmon fruits are summarized in Figure 1. Using blue SPME, at the ripe stage the main volatile groups detected were total terpenes (10.39%), total esters (9.37%), total aldehydes (37.76%), total acids (37.08%), total ketones (2.32%), and total alcohols (3.38%)(Figure 4). A total of 31 individual components were identified in the juice, comprising four alcohols, nine aldehydes, one ester, nine acids, three ketones, and five terpenes. Among the extraction methods tested, blue SPME proved to be the most suitable for isolating volatile compounds from persimmon juice.

Aldehydes and acids were found to be the predominant volatile groups in persimmon fruits (Table 4). Key aldehydes detected included hexanal (25.16%), (E)-2-hexenal (2.69%), and trans-2,4-dodecadialenal (2.63%), with notably higher levels in ripe fruits. Among acids, acetic acid (22.82%), nonanoic acid (2.62%), and hexanoic acid (2.07%) were the most abundant, also with higher levels in ripe fruits. Within the alcohol group, menthol (1.27%) and 1-octanol (0.82%) were prominent, particularly in ripe fruits. Esters such as 1,2-benzenedicarboxylic acid, diethyl ester (7.26%) were identified as important contributors to aroma and were highly abundant in ripe fruits. Esters are known to impart fruity and floral notes that play a critical role in cultivar differentiation. Regarding terpenes, benzene (isothiocyanatomethyl), benzene, 1-methyl-2-(1-methylethyl)-, and naphthalene, 1,6-dimethyl-

4-(1-methylethyl)- were the major compounds identified. Among them, benzene (isothiocyanatomethyl) was particularly abundant (6.52%) in ripe fruits (Table 4).

At the unripe stage, the main volatile groups detected were total terpenes (44.98%), total esters (1.39%), total aldehydes (10.23%), total acids (17.56%), total ketones (8.40%), and total alcohols (17.44%). A total of 27 individual compounds were identified in the juice, consisting of five alcohols, seven aldehydes, two esters, eight acids, three ketones, and four terpenes. Aldehydes and acids were again found to be the predominant volatile groups in persimmon fruits (Table 3). The key aldehydes detected included hydroxymethyl furfural (6.10%) and 2-furancarboxaldehyde (1.84%), both showing notably higher levels in unripe fruits. Among acids, acetic acid (5.29%), (E)-9-octadecenoic acid (5.10%), and pentadecanoic acid (4.81%) were prominent, also with higher abundance at the unripe stage. Within the alcohol group, linalool (7.10%), geraniol (3.76%), and nerol (3.48%) were prominent, particularly in ripe fruits. The major ketone identified was 2,3-dihydro-3,5-dihydroxy-6-methyl-4H-pyran-4-one (8.40%). Regarding terpenes, (+)-limonene (42.93%) was the dominant compound identified in unripe persimmon fruits. In the study, it was determined that with increasing ripeness, the amounts of aldehydes, esters, and acids increased, while the amounts of alcohols, ketones, and terpenes decreased. The results of the study revealed that the main factor responsible for changes in the aroma compounds of persimmon fruit was the progression of ripening over time. As the maturity index increased, the composition of aroma compounds also changed. Terpenes were found to increase up to a certain stage of ripening and then decrease in the later stages, with a higher number of terpene compounds identified in the unripe stage. Limonene was identified as the common terpene component in both cultivars.

In persimmon, the total alcohol content within the volatile compound profile decreased during ripening, whereas the proportion of ester compounds increased. In contrast, ketone levels showed a decreasing trend as ripening progressed. As fruits ripen, the quantity and quality of volatile compounds responsible for aroma increase, reaching their maximum at full maturity. The synthesis of aroma compounds is influenced not only by the genetic makeup but also by ecological factors, rootstock, cultivar, altitude, cumulative temperature during the growing season, ripening stage, and storage conditions. The source of aroma compounds largely comes from sugars, proteins, and fats metabolized during ripening. Therefore, aroma formation during ripening occurs not only through enzymatic synthesis but also through the breakdown and transformation of these metabolites. In other words, as the fruit ripens, volatile aroma compounds are primarily produced via metabolic degradation processes and enzyme activity (Perez et al., 1996; Kaynaş et al., 2022).

Besada et al., (2013) reported a high-resolution volatile profiling of fruits from 12 persimmon cultivars, identifying 67 compounds. This profiling was used to characterize the different astringency types of persimmon fruit before and after deastringency treatment. Fruits that do not naturally accumulate astringent compounds (PCNA type) exhibited high levels of **3(2H)-benzofuranone**, whereas this compound was not detected in any astringent-type fruits (non-PCNA). In addition, at harvest, PCNA cultivars showed higher accumulation of **benzeneacetaldehyde** and lipid-derived aldehydes (hexanal, heptanal, octanal, and decanal) compared to non-PCNA fruits. Wang et al., (2012) reported that gas chromatography–mass spectrometry (GC-MS) analysis of the extract led to the positive identification of 50 compounds, among which aldehydes emerged as the most important class of volatile compounds. Gas chromatography–olfactometry (GC-O) analysis of the aroma extract revealed that 32 compounds had an aroma impact. The six most intense aroma-impact compounds were methional, (E)-2-Hexenal, Phenylacetaldehyde, (E,Z)-2,6-Nonadienal, Hexanal, and Furaneol. The aroma qualities of these compounds largely explain the aroma profile of persimmon fruit, which was described as fresh peach, a touch of orange, sweet, woody, floral, green, and potato-like. The unambiguous identification of trace aroma-impact compounds – (E,E,Z)-2,4,6-Nonatrienal and (E,Z,Z)-2,4,7-Decatrienal – was achieved by applying a solid-phase extraction procedure for the selective isolation of carbonyl compounds using GC-MS.

CONCLUSION

The study observed a significant increase in TSS values and a decrease in titratable acidity (TEA) throughout the ripening process. Harvesting: For optimum quality, high TSS (18–20%) and low TEA (0.1–0.2%) values should be targeted at harvest. Therefore, producers are advised to pay attention not only to rind color but also to the sugar/acid balance. In terms of sugar composition, glucose and fructose levels increase with ripening, while sucrose levels gradually decrease. This can be explained by the high activity of the invertase enzyme (Bubba et al., 2009; Santos et al., 2019). Sugar-acid balance: Sweetness (high glucose + fructose) and low acidity (reduction of malic and citric acid) play important roles in consumer taste. Therefore, post-harvest ripening methods (CO₂, ethylene, limewater) should be used to improve flavor balance. In terms of organic acids, it has been observed that malic and citric acid levels gradually decrease during the ripening process, resulting in a decrease in acidity and an increase in sweetness perception. In terms of volatile compounds, aroma compounds, particularly aldehydes, esters, and furaneol, have been found to vary with ripening and contribute to the fruit's characteristic aroma (Wang et al., 2012; Besada et al., 2013). Storage conditions: Because persimmon is climacteric, low-temperature and controlled-atmosphere storage conditions are important for maintaining the sugar-acid balance in the fruit and preventing aroma loss. The Hachiya variety, with its high sugar and aroma profile, can be utilized in drying, juice, and functional food products to create value-added products. The TSS, TA individual sugars, organic acids, and aroma values obtained from the analyses were found to be at sufficient levels in the final harvest period in terms of fruit edibility. Detailed examination of sugar and organic acid metabolism in different genotypes, correlation with consumer taste, and monitoring of changes during storage are recommended.

ABSTRACT

Consumers experience health problems with egg consumption and also preference of vegan and vegetarian nutrition leads to the search for alternative egg substitutes in new product development. This research determined the quality and acceptability of Turkish noodle (Erişte) substituted with 25%, 50%, 75% and 100% chickpea aquafaba instead of egg. Erişte were analyzed for physical, textural, and sensory properties compared with sample containing egg. An increase in substitution led to a rise of 12.76% in water uptake, 12.94% in volume increase and 40.19% in the cooking loss. The addition of up to 75% aquafaba increased the firmness of .erişte significantly compared to the control sample. Erişte sample containing 100% aquafaba showed significantly $p < 0.05$ higher values in L^* (75.11) and hue angle (94.85), while lower values in a^* (-2.13), b^* (24.30) and saturation index (24.39). The odor (7.00), taste (7.00), appearance (7.00), chewiness (7.00) and overall acceptability (6.88) of samples containing aquafaba were found more acceptable than control sample (4.00, 5.50, 5.90, 5.95 and 5.47, respectively). Based on our results, possible to produce erişte with acceptable sensory properties, and good physical quality product by adding up to 50% aquafaba.

Keywords: Aquafaba, egg-less noodle, physical properties, textural properties

INTRODUCTION

Turkish pasta (Erişte) is one of the traditional Turkish foods was generally produced from wheat flour, salt and egg. Milk, whey powder and some other additives can also be added in different regions of Turkey (Özkaya et al., 2004). The high rate of egg component used in pasta products can reduce production and consumption due to both the cost of the product and various reasons. So, many issues such as changing consumer preferences, increasing allergens, improving food safety, improving nutritional balance, reducing price variability and supporting environmental sustainability have increased the interest in researching egg substitutes and alternatives (Grizio and Specht, 2018).

Plant-based proteins are one of the most important food components to use as egg substitution in product development. Recently, the viscous liquid obtained from cooked chickpeas or other legumes and pulses called 'aquafaba' according to the Latin origin of water (aqua) and beans (faba) has been recently used as eggs replacement in many foods (Erem et al., 2021). Some studies in the literature revealed that aquafaba has many functional properties such as water and oil holding capacity, emulsion stabilizer, foaming, gelling and thickening in various formulations (Mustafa and Reaney 2020) and can be used as an egg substitute in vegan products (Raikos et al., 2020).

Aquafaba has used in meringue (Stantiall et al. 2018), sponge cake (Mustafa et al. 2018) and vegan mayonnaise (Raikos et al., 2020) as an emulsifier instead of egg. To our knowledge, no studies have been conducted on the inclusion of aquafaba in the formulation of egg-less Turkish pasta (Erişte). The objective of this study was to investigate egg substitutes for Turkish pasta using aquafaba. The effects of aquafaba on physical, textural and sensory properties of eggless pasta were evaluated.

MATERIAL AND METHOD

Materials

Commercial chickpea, wheat flour, whole egg and salt were purchased from local markets in Konya, Turkey.

Methods

Production of Aquafaba

Aquafaba was prepared according to the method described by Baik and Han (2012) with some modifications. Firstly, chickpeas were washed and were cleared from dirt, dust and foreign matter. Aquafaba was obtained by cooking 100 g chickpea in 500 mL water (1:5 chickpea/water ratio) for 30 min in boiling water at 98 °C. After the cooking, water and cooked chickpeas waited for 12 hr in a refrigerator at 4 °C. Finally, aquafaba was obtained by removing cooked chickpeas.

Production of Turkish noodle (Erişte)

For production of control Turkish pasta sample, firstly wheat flour (100 g), whole egg (40 g), salt (1 g) and water were mixed and kneaded in a laboratory-type mixer (Hobart N50, Offenburg, Germany) for 8 min. The kneaded dough rested for 20 min and 2 mm thickness/5 mm wide long strips were obtained (1 time in section 6 and 7) by a pasta machine (Shule Pasta Machine; Jiangsu, China). Then, strip-shaped dough were cut to a length of 4 cm. The drying of samples took place in a laboratory-type oven (Nüve KD 200, Ankara, Turkey) at 50 °C for 18 h. In the other samples, aquafaba were replaced at levels of 25, 50, 75 and 100% on the basis of whole egg. The samples were preserved in sealed polyethylene bags at 4 °C.

Cooking properties

Volume increase, weight increase and cooking loss values of pasta were determined according to Bilgiçli et. al. (2011). The weight increase and volume increase were found by differences of dry and cooked erişte samples weights and by the volume difference of water overflow, respectively. For cooking loss determination, cooking water was evaporated to constant weight in an oven and the weight of total solids expressed as a percentage (AACC, 2000).

Texture analysis

The firmness values of erişte samples were measured by TAXT Plus Texture Analyser (Stable Microsystems, Surrey, UK) and A/LKB-F was used as a probe (AACC, 1990). Firstly, 10 g samples were cooked in 200 mL distilled water for optimum cooking time and drained. Then, three strips of erişte sample were placed onto the stand and analyzed.

Color analysis

Color measurement was made by measuring L* value [(0) black- (100) white], a* value [(+) red- (-) green] and b* value [(+) yellow - (-) blue] using the Hunter Lab Color Quest II

Minolta CR-400 (Konica Minolta Sensing, Inc., Osaka, Japan) (Francis, 1998). Three measurements were taken on each sample. The hue angle and the saturation index value were determined with $\arctan(b^*/a^*)$ and $(a^{*2}+b^{*2})^{1/2}$ equations, respectively.

Sensory analysis

Sensory analysis was carried out for cooked Turkish pasta samples. Turkish pasta samples were evaluated in terms of color, odor, taste, appearance, chewiness and general acceptability properties by 12 panelists (aged 20–50). Sensory properties of samples were scored using a 7-point hedonic scale in which a score of 7 = like extremely, 1 = dislike extremely.

Statistical analysis

The results were expressed as mean $\pm$ standard deviation and were analyzed using the Statistical software JMP 5.0.1 (SAS Institute). The averages of the main variation sources were compared at $p < .05$ level. All measurements were performed in duplicate for each sample.

RESULTS AND DISCUSSION

The data on the effect of different levels of aquafaba on the cooking quality and firmness properties are shown in Table 1. The water uptake values of Turkish pasta samples increased with the use of more than 50%. Compared to control, addition of aquafaba increased volume increase value of Turkish pasta samples from 219.69 to 248.11%. Similar behavior in terms of cooking loss properties was observed Turkish pasta samples produced with different aquafaba. While Turkish pasta prepared with 50-100% legume flour revealed the highest cooking loss, the addition of 25% aquafaba showed similar cooking loss with control sample. The findings of this study demonstrated that the addition of aquafaba increased 1.82-fold with 100% aquafaba the firmness values of pasta samples compared to the control sample (Table 1).

Table 1. Physical properties of Turkish pasta¹

	Water uptake (%)	Volume increase (%)	Cooking loss (%)	Firmness (g)
Control	215.59 $\pm$ 1.89b	219.69 $\pm$ 6.03b	4.23 $\pm$ 0.11b	642.12 $\pm$ 23.35c
25% Aquafaba	220.06 $\pm$ 3.44b	229.72 $\pm$ 4.81ab	4.75 $\pm$ 0.25b	698.98 $\pm$ 61.62c
50% Aquafaba	236.70 $\pm$ 3.03a	244.86 $\pm$ 6.52a	5.43 $\pm$ 0.10a	809.39 $\pm$ 90.10bc
75% Aquafaba	238.14 $\pm$ 1.25a	245.15 $\pm$ 5.82a	5.74 $\pm$ 0.16a	988.47 $\pm$ 35.67ab
100% Aquafaba	243.12 $\pm$ 3.16a	248.11 $\pm$ 3.95a	5.93 $\pm$ 0.13a	1166.62 $\pm$ 92.43a

¹Means followed by the different letters within a column are significantly ($P < 0.05$) different.

Color values of Turkish pasta samples are demonstrated in Table 2. Color L*, a*, and b* results of Turkish pasta samples varied in the range of 65.24-75.11, 0.26-(-2.13), and 24.30-30.56, respectively. Compared to the control sample, the addition of aquafaba into the formulation of Turkish pasta significantly ($p < .05$) increased L*, but decreased a* and b* values. The findings are associated with the natural color properties of eggs. The reason of this result was lower lightness and higher yellowness values of egg compared with aquafaba. The SI value of Turkish pasta sample incorporated with 100% aquafaba were lower than the control and other samples. The hue angle values demonstrated an increase with high aquafaba usage ratio.

Table 2. Color properties of Turkish pasta¹

	L*	a*	b*	Saturation Index	Hue angle
Control	65.24±1.58c	0.26±0.07a	30.56±0.83a	30.56±0.77a	89.51±0.58b
25% Aquafaba	67.72±1.98bc	-	29.94±0.69a	29.94±0.10a	90.71±0.99b
50% Aquafaba	70.52±1.37abc	0.37±0.10b	29.73±0.59a	29.74±0.84a	91.77±1.02ab
75% Aquafaba	73.12±1.87ab	0.92±0.14c	28.50±1.92ab	28.58±0.68a	94.27±0.35a
100% Aquafaba	75.11±0.66a	2.06±0.03d	24.30±1.00b	24.39±0.52b	94.85±0.91a
Aquafaba		2.13±0.04d			

¹Means followed by the different letters within a column are significantly ($P < 0.05$) different

Sensory properties of Turkish pasta samples are presented in Figure 1. According to the results; color score shown no any change with incorporation of aquafaba in pasta formulation. When compared with the control sample, the odor, taste, appearance, chewiness and overall acceptability scores of the Turkish pasta samples were found higher with high aquafaba addition levels, statistically. As a result, 50% and more aquafaba usage improved the sensory properties and overall acceptability of Turkish pasta. Mustafa et al. (2018) prepared sponge cake with egg white and aquafaba. The color and texture of sponge cake made with egg white or aquafaba was similar and acceptable, but cakes made with aquafaba were less pliable and less sticky than cakes made with egg whites.

Figure 1. Sensory properties of Turkish pasta

Aslan and Ertaş (2020) used aquafaba as an egg substitute in the cake formulation. According to the results of sensory evaluation, they reported that samples containing 25% aquafaba were preferred more by the panelists.

CONCLUSIONS

In this study, the usability of aquafaba as egg substitute in Turkish pasta (Erişte) production was investigated. According to results, the use of aquafaba as an egg substitute was concluded with an increase in the water uptake, volume increase and cooking loss of pasta samples and so, in terms of cooking quality properties considerably not caused a negative effect

up to 50% ratio. Also, the use of aquafaba increased the firmness values compared to the control samples. The incorporation of aquafaba in the pasta samples positively affected the sensory profile in terms of all sensory scores except to color scores.

ABSTRACT

Secondary plant metabolites are rich sources of bioactive substances, which have shown to possess several beneficial health effects including antioxidant, antihemolytic and anti-inflammatory activities. This study aimed to evaluate the phytochemical composition and antioxidant activities of plants extracts from the ginger (*Zingiber officinale*). Polyphenols were estimated by the Folin-Ciocalteu method and total flavonoids by the AlCl₃ method in the aqueous and hydro-methanolic extracts. The antioxidant capacity was determined by the DPPH and FRAP tests. The results showed that the ginger extract in maceration, by methanol, is very rich in triterpenes, steroids, and the decoction, by distilled water, is rich in starch. The antioxidant activity of our extracts indicated that the polyphenols were more present in the maceration extract ($1.46 \pm 0.006 \mu\text{g EAG/g}$) compared to the decoction ($1.40 \pm 0.003 \mu\text{g EAG/g}$), as well as flavonoids in decoction (0.72 ± 0.000) and maceration ($3.57 \pm 0.422 \text{ mg EAG/g}$). Methanolic extract reveals a very great antioxidant activity compared to the decoction. The analysis of the toxicity of *Zingiber officinale* demonstrated an average rate which does not exceed a percentage of hemolysis of 58% for the two extracts. The study of anti-inflammatory activity of human red blood cells has been proven by the calculation of the percentage of inhibition of hemolysis very high in all extracts.

The findings suggest that *Zingiber officinale* possess large antioxidant properties, a lower percentage of cytotoxicity and a very good anti-inflammatory activity and could serve to protect human from oxidative damage caused by free radicals.

Keywords: *Zingiber officinale*, phytochemical screening, DPPH, TFC, FRAP

INTRODUCTION

Medicinal plants are still the main source of new drugs, and are considered an essential raw material for the discovery of new molecules needed to develop future medicines. In addition, these plants have played a vital role in the development of human culture around the world (Khan et al., 2019).

In particular, many aromatic plants and spices have attracted the interest of numerous research groups (Bellik et al., 2013). Ginger, the rhizome of *Zingiber officinale*, has been used as a food, spice, supplement and flavouring agent for over 3000 years in countries such as Burma, China, Congo, Germany, Greece, India, Indonesia, Japan, Sri Lanka, Tibet, and the United States due to its beneficial properties such as pungency and aroma (Kubra and Rao, 2012 ; Kiyama, 2020). It is also used in traditional medicine to treat nausea, indigestion, abdominal pain, colic, and constipation. The rhizomes of *Z.officinale* are often chewed raw and the juice swallowed to relieve generalised abdominal pain. *Z.officinale* is also used as a respiratory aid to relieve coughs (Amir et al., 2011).

This plant material contains a large number of molecules with multiple uses in the food industry, cosmetology and pharmaceuticals. These include steroids, alkaloids, phenolic acids, tannins, terpenes and flavonoids (Bahorun et al., 1996).

Thus, the evaluation of phytopharmaceutical, anti-inflammatory and anti-haemolytic properties remains a very interesting and useful task, particularly for a plant whose use is less frequent or unknown in traditional medicine. Secondary plant metabolites are rich sources of bioactive substances, which have shown to possess several beneficial health effects including antioxidant, anti inflammatory and antihemolytic activities.

Given its characteristics, ginger has been extensively studied for its biological activity. The free radical scavenging properties of its compounds have been well established as antioxidants (Bellik et al., 2014).

Therefore, this study aimed to evaluate the phytochemical composition and biological activities for two ginger extracts obtained by maceration and decoction. Polyphenols, total flavonoids, and total tanins were estimated in the aqueous and hydro-methanolic extracts. We also determined the antioxidant capacity by DPPH and FRAP tests, as well as the in vitro anti inflammatory and anti hemolytic activities of extracts of ginger.

MATERIAL AND METHOD

The plant material used in this study corresponds to the *Zingiber* species under the name *Zingiber officinale*, that was obtained from a herbalist in the wilaya of Tlemcen (Fig 1).

Preparation of ginger extracts:

First of all, we began by washing the ginger rhizome several times, then peeling it and cutting it into small pieces. Next, we ground the pieces in a blender until we obtained a ginger homogenate. Finally, the ginger homogenate is put in a box and stored in the refrigerator at a temperature (3 to 4°C) until use.

Different extracts of ginger were prepared by decoction in distilled water, by maceration method in water-methanol (20/80, v/v) according the protocole described by Tuma et al. (2004). The decoction was prepared with 10g of ginger homogenate that is placed in 100 mL of distilled water, bring to the boil (100°C) in a beaker for 15 minutes, then the mixture is filtered and recovered.

10g of ginger homogenate is macerated in 100 mL of water-methanol (20/80; V/V) for 24 hours at room temperature. This operation is repeated three times, renewing the solvent each time. The macerates are filtered through filter paper each time and the three filtrates are combined. Most of the solvent is removed from the filtrate under vacuum at 40°C using a rotary evaporator, and the remainder is removed using an oven at 40°C.

Phytochemical screening

This qualitative test was carried out for the presence of various phytochemical constituents like saponins, tannins, flavonoids, steroids, terpenoids, alkaloids, glycosides, as per standard methods.

Saponin Analysis

2 ml of extract is shaken vertically for 30 seconds until a stable foam forms (height greater than 1 cm), and let stand for 15 min.

Tannin Analysis

By adding 1 mL of aqueous extract, 1 mL of water and 1-2 drops of diluted FeCl₃ (1%), tannins can be detected. After incubation, the presence of catechin or gallic tannins is indicated by a dark green or blue-green colour, respectively.

Figure 1. Zingiber officinale Rhizome

Test for Proanthocyanidols

A positive reaction occurs when a purple colour appears after adding 2 mL of infused water to 2 mL of concentrated hydrochloric acid and allowing the mixture to stand in a boiling water bath for 5 min.

Test for Flavonoids

1 mL of the extract is mixed with 1 mL of concentrated HCl and 3 turns of magnesium. The appearance of a pink, red or yellow colour indicates the presence of flavonoids.

Analysis of Steroids

Tilting the tube at a 45-degree angle while adding 1 mL of sulphuric acid to the ginger extract, the mixture turn to red, and indicated the presence of unsaturated sterols.

Analysis of Anthocyanes

2 mL of hydrochloric acid are added to 2 mL of ginger extract, where a pink-red colour appears, then ammonia is added, which gives a blue-purple colour indicating the presence of anthocyanins.

Test for Alkaloids

1 mL of crude extract was mixed with 5 mL of hydrochloric acid, then add 5 drops of Meyer's reagent. A white or brown precipitate will form, indicating the presence of alkaloids.

Phenolic compounds

Total phenolic compounds

Polyphenol determination was performed by spectroscopic method using the Folin-Ciocalteu assay according to the method described by Singleton and Rossi (1965). 200 μ L of each extract were mixed with 0.8mL of sodium carbonate solution (7.5%), and 1mL of Folin-Ciocalteu reagent diluted 10 times. The mixture is shaken and incubated in dark for 30 min at room temperature. The absorbance was measured at 765 nm and compared to a standard curve with gallic acid. The polyphenol content was expressed as mg of Gallic acid equivalents per gram of dry weight (mg GAE/g DW). All tests are performed in triplicate for each sample.

Total Flavonoid's compounds

The favonoids of the extracts was performed by the aluminum chloride colorimetric method (Neupane and Lamichlane, 2020). A very stable complex was formed between aluminum chloride and the oxygen atoms on the carbon 4 and 5. At 430 nm, the absorbance was measured against a blank and the calibration curve was performed under the same conditions by quercetin

(0-1000 $\mu\text{g mL}^{-1}$). The results were expressed as mg of quercetin equivalents per g of dry weight (mg EQ/g DW).

Antioxidant activities

DPPH radical scavenging activity

The antioxidant activity of ginger extracts was evaluated by the DPPH method as described by Sanchez-Moreno et al. (1998). In this assay, 50 μL of the extract in methanol was mixed with 1,95 mL of methanol DPPH solution (0.025 g/L).

Antioxidants reduce DPPH, which has a purple colour into a yellow compound, the absorbance reading was taken at 515 nm against a blank containing the DPPH solution. The activities of the different extracts were compared to ascorbic acid used as the standard antioxidant. The results were expressed as a percentage of inhibition (%AA).

$$\%AA = (\text{Abs}_{\text{control}} - \text{Abs}_{\text{test}} / \text{Abs}_{\text{control}}) \times 100$$

50% of DPPH radical inhibition (IC₅₀) was calculated graphically by linear regression of the plotted graphs between the percentages of inhibition and different concentrations of the fractions tested. It should be noted that the lower the IC₅₀ value, the greater the activity of the extract tested (Ondua et al. 2019).

Ferric reducing antioxidant power (FRAP)

The concept of this method is to evaluate the reducing activity in ferric iron Fe(III) molecules extracts of the FRAP complex to ferrous iron to Fe(II), by measuring the blue colour of the compound (Prussian blue) which absorbs at 700 nm. High absorbance indicates that the sample has high reducing power.

1 mL of different extracts at different concentrations were combined with 2.5 mL of phosphate buffer (0.2 M, pH 6.6) and 2.5 mL of 1% potassium ferricyanide complex K₃[Fe(CN)₆]. After, 20 min of incubation at 50 °C, the reaction is halted by adding of 2.5 mL of trichloroacetic acid (10%) solution. Then, tubes were centrifuged at 3000 rpm for 10 min. After that, 2.5 mL of each supernatant was mixed with 2.5 mL of distilled water and 500 μL of (FeCl₃, 6H₂O) (0.1%). The absorbance was measured at 700 nm against a blank, and ascorbic acid was used as a standard under the same operating conditions.

In vitro anti-inflammatory activity

In order to evaluate the inflammatory activity of plant extracts, we applied the in vitro protein denaturation inhibition test (Rajesh et al., 2019). The method consists of inhibiting the denaturation of bovine serum albumin (BSA) by heating the extracts to 72°C.

A 0.2% BSA solution was prepared in Tris-HCl buffer (0.05 M, pH 6.6). To 1 mL of this solution, 1 mL of each extract at different concentrations (100, 150, 250, 500 $\mu\text{g/mL}$) or of the standard (diclofenac sodium) was added. After incubation at 37°C for 15 min, the test tubes were heated at 72°C for 5 min to induce denaturation, and then cooled for 10 min. The absorbance of these solutions was determined at a wave length of 660 nm. Each experiment was carried out in triplicate and the mean absorbance was recorded.

The percentage of inhibition of protein denaturation inhibition was determined on a percentage basis relative to control using the formula :

$$\text{Per cent inhibition of protein} = 100 - \left[\left\{ (\text{At} - \text{Ac}) / \text{At} \right\} \right] \times 100.$$

At = Absorbance of test solution (tested extract). Ac = Absorbance of control

Anti-hemolytic activity

The anti-hemolytic effect of an extract is assessed in vitro using an erythrocyte model. The evaluation of anti-hemolytic activity is based on the ability of extracts to stabilise the membrane of human erythrocytes when subjected to osmotic stress induced by a hyposaline solution. In the presence of a protective agent (such as a plant extract with membrane-protective properties), membrane integrity is preserved, reducing the release of haemoglobin. The degree

of hemolysis is quantified by measuring the absorbance of the supernatant at 560 nm, with the inhibition efficiency expressed as a percentage. A human erythrocyte suspension at 10% was prepared from whole blood collected in heparinised tubes, then centrifuged at 3000 rpm for 10 min.

The resulting cell pellet was washed three times with 0.9% isotonic NaCl solution. For the evaluation, 0.5 mL of the extract to be tested (diluted in 0.9% NaCl) was mixed with 1.5 mL of phosphate buffer (PBS, 0.15 M, pH 7.4) and 2 mL of hyposaline solution (0.36% NaCl). This mixture was incubated at 37°C for 20 min. Next, 0.5 mL of the erythrocyte suspension was added, followed by incubation at 56°C for 30 min. After rapid cooling, the tubes were centrifuged at 3000 rpm for 5 min. The absorbance of the supernatant was measured at 560 nm to assess the hemolysis rate. Gallic acid was used as a positive control. The percentage of hemolysis was calculated using the following equation :

$$\text{Hemolysis rate \%} = [(Ac - At) / Ac] \times 100$$

Ac = Absorbance of control. At = Absorbance of test solution (tested extract).

RESULTS AND DISCUSSION

Phytochemical screening was performed by employing standard screening tests. According to the results, *Z.officinale* is rich in saponins, terpenoids and steroids (Table 1). It should be noted that the ginger maceration and decoction extracts studied differ in terms of their secondary chemical composition.

However, there are similarities between these two extracts, namely the total absence of tannins (hydrolysable), proanthocyanidols (condensed tannins), flavonoids, anthocyanins and alkaloids.

Contents of total polyphenols and flavonoids

The total polyphenol content of *Zingiber officinale* was assessed using the Folin Ciocalteu method to determine the total number of polyphenols present in the two ginger extracts.

The results of our study show that ginger maceration extract is rich in polyphenols compared to decoction extract (Table 2).

Oueslati et al. (2018) show that the 30% methanolic extract has a total polyphenol content of 51.7 mg EAG/ g of extract. According to Hammoudi and Fekiri (2021), the phenolic compound content of natural dried ginger water extract was 68.05 ± 04.02 mg EAG/g of extract. Thus, based on these results, we conclude that the extract containing a large amount of polyphenols is the aqueous extract of natural dried ginger. However, this difference in polyphenol content may also be due to species diversity, climatic conditions, maturity and different extraction processes such as the type of solvent, temperature and extraction time (Popovici et al., 2009).

Table 1. Phytochemical composition of Ginger

Phytochemical compounds	Methanolic extract	Water extract
Saponosides	+	+
Tannins	-	-
Proanthocyanidols	-	-
Flavonoids	-	-
Terpenoids and Steroids	+++	+
Anthocyanes	-	-
Alkaloids	-	-

(+++)= Prominent; (+) = very less present; (–) = Absent.

The results reveal that methanolic ginger extract is richer in flavonoids than aqueous extract. This difference could be explained by the temperature factor (Table 2).

We compared the results of the current study of ginger extract (maceration and decoction) with chloroform extract (ECh), ethyl acetate extract (EAE), n-butanol extract (ENB), hexane extract (EH) carried out by Mameri and Sadaoui (2019), and microwave-dried ginger powder by Bourai and Azzouk (2018). The results indicate that there is indeed a difference in the amount of flavonoids present in the extract in our study compared to the extracts in the other studies. In fact, the flavonoids in our two extracts are poorer than ENB, EAE, EH, and ECh, whose respective contents are 47.61, 81.55, 83.036, and 89.77 $\mu\text{gEQ/mg}$ of extract. All these results show that using solvents with different polarities (methanol/water and chloroform, etc.) allows different quantities of flavonoids to be extracted.

Antioxidant activity

In this study, the antioxidant activities of Ginger extracts were evaluated by DPPH and FRAP assays using ascorbic acid as a standard.

According to table 2, methanolic extract presents a high significant DPPH activity, expressed by the lowest IC₅₀ compared of the aqueous extract. Then, FRAP analysis revealed a powerful activity of methanolic extract compared with aqueous extract.

Phenolic compounds are responsible for the antioxidant activities of plants. DPPH and FRAP assays were used to assess the antioxidant activity of plant extracts. This study is not similar to those of Meghezzi and Dali (2018), where methanolic extract has antioxidant activity with an IC₅₀ of 0.22 mg/mL, and Amari (2016), who showed that the extract of *Z. officinale* rhizomes has antioxidant activity with an IC₅₀ of 5.23 mg/mL. This variability in IC₅₀ may be due to geographical diversity, extraction methods, and whether the rhizomes were fresh or dried.

Our extracts have very low reducing power compared to the work of Beggas and Bendoukhane (2017), who found an EC₅₀ of 1.74 mg/mL for HG. The study on dried ginger also showed that *Zingiber officinale* has antioxidant capacity, with an EC₅₀ of 3.915 mg/mL (Hammoudi and Fekiri, 2021). Finally, the extract with the best reducing activity is the methanolic extract at a concentration of 0.13 mg/mL.

Table 2. Total phenolics and flavonoids content in the extracts of Ginger

Extract	Total phenolic content ($\mu\text{g EAG/mg}$ of extract)	Total flavonoid content ($\mu\text{g EQ/g DW}$)	DPPH IC ₅₀ ($\mu\text{g/mL}$)	FRAP EC ₅₀ ($\mu\text{g/mL}$)
Maceration	1.46 ± 0.006	3.57 ± 0.422	$32.02 \pm 0.30^*$	$130.11 \pm 0.28^*$
Decoction	1.4 ± 0.003	0.72	$52.83 \pm 0.31^{**}$	$163.27 \pm 0.30^{**}$
Ascorbic acid	-	-	27.17 ± 0.42	95.6 ± 0.50

Values are means of three replicates $\pm$ SD. The values are significantly different, * $P < 0.05$, and ** $P < 0.01$. EAG: equivalent gallic acid; EQ: equivalent quercetin; DW: dry weight

In vitro Anti hemolytic and anti inflammatory activities

The present results exhibited a concentration dependent inhibition of protein (albumin) denaturation by the extracts. The percentage values were obtained using various concentrations of test compounds, and readings are presented as the mean of triplicates.

The results obtained suggest a proportional relationship between the increase in concentration and the percentage inhibition of BSA denaturation, both for diclofenac and for the two ginger extracts.

Comparative analysis reveals that the percentage inhibition of BSA denaturation induced by plant extracts remains lower than that observed with diclofenac. At a concentration of 500 µg/ml, the latter showed a maximum inhibition of $94.86 \pm 5.7\%$. In contrast, at a concentration of 500 µg/ml, the maceration extract showed an inhibition rate of $76.06 \pm 4.43\%$, while that of the decoction extract was $68.35 \pm 7.67\%$ (Fig.2)

Maceration, which is carried out at room temperature or slightly heated, better preserves the integrity of heat-sensitive compounds such as flavonoids, polyphenols and other secondary metabolites, known for their anti-inflammatory pharmacological properties. Several studies have shown that flavonoids possess potent anti-inflammatory activity in models of acute and chronic inflammation by inhibiting lipid peroxidation, platelet aggregation, and capillary permeability.

The study of the anti-hemolytic activity of extracts obtained by maceration and decoction, compared to gallic acid, reveals marked differences depending on the extraction method and concentrations used. Analysis of the results shows a positive correlation between the concentration of the extracts and the percentage of hemolysis, reflecting a dose-dependent activity.

At low concentrations (100 µg/ml), the hemolytic activity of gallic acid is significantly higher (57%) compared to extracts obtained by maceration (12%) and decoction (23%). This result suggests that gallic acid, as a pure compound, has a more direct and effective action on red blood cell lysis than complex extracts. However, the relatively moderate activity of the extracts at this concentration could be attributed to the low amount of bioactive compounds released or the presence of antagonistic compounds (Fig. 3).

When the concentration increases to 125 µg/ml and 250 µg/ml, a gradual increase in hemolysis is observed for all types of samples. In particular, the maceration extract reaches 65% at 250 µg/ml, approaching the efficacy of gallic acid (84%), while the decoction reaches only 49%. This difference can be explained by the better preservation of heat-sensitive metabolites, such as polyphenols and flavonoids, during maceration. At maximum concentration (500 µg/ml), the maceration extract exhibits hemolytic activity almost equivalent to that of gallic acid (82% versus 80%), while the decoction peaks at 51%. This result corroborates the hypothesis that maceration is a more favourable method for extracting the active ingredients responsible for hemolytic activity.

Figure 2. Percentage inhibition of BSA denaturation

Figure 3. Percentage inhibition of hemolysis

CONCLUSIONS

The findings suggest that *Zingiber officinale* possess large antioxidant properties, a lower percentage of cytotoxicity and a very good anti-inflammatory activity and could serve to protect human from oxidative damage caused by free radicals.

SOUS-VIDE: AN INNOVATIVE APPROACH TO COOKING AQUATIC PRODUCTS

Nalan GÖKOĞLU

Akdeniz University, Fisheries Faculty, Antalya, Türkiye

Corresponding author e-mail: ngokoglu@akdeniz.edu.tr

ABSTRACT

Cooking is a heat treatment used to make food edible, ensure microbial safety, and enhance flavor. To achieve these goals, foods are prepared using various cooking methods. Traditional techniques such as frying, baking, grilling, and boiling are widely used for cooking seafood.

Cooking transforms food into more easily edible and digestible products with improved taste and extended shelf life through various physical and chemical processes. However, depending on the cooking method and conditions, it can also result in the loss of nutritional value and sensory properties, as well as the formation of undesirable compounds. For example, frying can lead to health problems such as obesity, hypertension, and cardiovascular diseases. Grilling may result in the formation of toxic substances while baking and boiling can cause the loss of essential nutrients. Today's consumers tend to prefer healthy foods that retain their nutritional value. In recent years, sous-vide, a cooking method that addresses these preferences, has emerged as an innovative technique for preparing aquatic products. Sous-vide technology, also known as "cooking under vacuum," involves cooking vacuum-sealed products in a water bath with precise control of time and temperature. This method helps preserve the product's nutritional value and flavor, prevents undesirable changes, particularly the formation of off-flavors and odors caused by oxidation, and extends shelf life. In this presentation, information will be provided on sous-vide cooking of fish and other seafood, which are nutritionally valuable but highly perishable.

Keywords: Sous-vide, cooking, fish, seafood

INTRODUCTION

Sous-vide, which means "cooking under vacuum" in French, means cooking foods packaged under vacuum in heat-resistant bags at a precise temperature and for a certain period (Zakrzewski et al., 2023). Sous vide products, cooked in vacuum bags, rapidly cooled, and stored in the cold, are ready-to-eat foods. In recent years, as consumer habits have changed, the demand for ready-to-eat foods has increased. With increasing consumer awareness, interest in methods that will minimize nutritional losses in foods has also increased. Sous vide-cooked foods meet these demands (Bhattacharya et al., 2024). Sous-vide technology can be applied to a wide range of products, from vegetables to soups, meat and meat products, and various sauces. Products prepared with this technique are sold as ready-to-eat foods and are suitable for use in all fast-food outlets. Therefore, it is believed that increasing its commercial production and sales will greatly benefit consumers. Sous-vide cooking method emerged in the 1960s as a result of French chefs' efforts to improve cooking quality and has become a method used globally today. The vitamin and mineral losses may occur with traditional cooking methods. Sous-vide reduces these losses (Misu et al., 2024). Due to sous-vide cooking used low temperatures, food cooks evenly, ensuring the inside is properly cooked without overcooking the outside, and preserving

the food's moisture. It ensures the juiciness and tenderness of meats and enhances the flavor of foods (Przybylski et al., 2021; Modzelewska-Kapituła et al., 2022; Kowalska et al., 2023).

Except for some products eaten raw, seafood is cooked. Traditional methods for cooking seafood include frying, grilling, baking, and steaming. Cooking seafood is primarily done to make it edible, but it also increases flavor, shelf life, and food safety. Heat treatment affects color, texture, and nutritional value (Abraha, 2018). However, traditional methods can lead to losses in nutritional value and flavor. Furthermore, at high temperatures, losses in water-soluble nutrients such as vitamins and minerals reduce their nutritional value (Puertollano et al., 2011). These methods also affect textural properties because they occur at high temperatures (Hassoun et al., 2021; Yang et al., 2023). The seafood products are rich in high biological value protein, unsaturated fatty acids, vitamins, and minerals. Therefore, it is important to cook and process them using methods that preserve their nutritional value. Furthermore, due to their perishable nature, methods that extend self-life and ensure safety are needed.

SOUS-VIDE COOKING PROCESS

Sous-vide technology is based on two applications that distinguish it from traditional cooking: (1) vacuum packaging of the product in a heat-resistant plastic bag, (2) cooking at precisely controlled temperature and time (Baldwin, 2012). The process steps of sous-vide cooking are as follows:

Vacuum packaging

Foods to be cooked sous-vide are placed in bags made of heat-resistant, air- and gas-tight plastic material and then packaged under vacuum (Karki et al., 2022). Vacuum packaging provides effective heat transfer from water to food, ensures uniform heat distribution throughout the food, and thus ensures even cooking. It extends the shelf life of food by eliminating the risk of recontamination during storage. It prevents unpleasant odors that may occur due to oxidation. It prevents the loss of moisture and volatile aromatic compounds and the growth of aerobic bacteria during cooking (Abel et al., 2022).

Cooking at controlled temperature

The vacuum bags containing the food are immersed in the water bath of the sous-vide equipment. The equipment is set to the target cooking temperature and cooked under precise temperature control. Since the temperature is constant and controllable in sous-vide cooking, the food can reach the desired degree of doneness, and the same quality product can always be obtained. This precise control minimizes the risk of overcooking while preserving sensitive proteins and natural flavours (Bhattacharya et al., 2024).

Cooling

After the cooking process is completed, the bags are removed from the water bath and quickly cooled to 2-3°C. Cooling must be rapid due to the possibility of spore-forming bacteria surviving during cooking (Bhattacharya et al., 2024). This prevents the proliferation of viable bacterial cells and spore germination.

Storage

To control bacteria that can survive during the cooking process and prevent the growth of anaerobic spore-forming bacteria such as *Clostridium botulinum*, *Clostridium perfringens*, and *Bacillus cereus*, chilled food should be stored at <3°C (Zavadlav et al., 2020).

ADVANTAGES AND DISADVANTAGES OF SOUS-VIDE COOKING

Sous-vide cooking has several advantages. It prevents moisture loss and, consequently, weight loss. The moisture loss that occurs in traditional cooking methods also leads to the loss of nutritional components. However, sous-vide cooking prevents water loss, resulting in a juicier and more tender meat, while also preserving nutrients by preventing the loss of water-soluble vitamins and minerals (Misu et al., 2024). In sous-vide cooking, lipid oxidation is significantly reduced thanks to the controlled, low temperature and vacuum packaging. This also reduces flavor and nutritional losses caused by lipid oxidation (Ayub and Ahmad, 2019). Since oxygen is removed from the environment with vacuum packaging, the risk of aerobic bacteria development is reduced, sous-vide cooking extends the shelf life of the food (Misu et al., 2024). In addition, since vacuum packaging reduces the risk of recontamination during storage, the shelf life is extended (Baldwin, 2012). Controlled temperature-time parameters ensure that the food is cooked at the desired rate and homogeneously (Baldwin, 2012; Ayub and Ahmad, 2019). Aroma losses and textural changes caused by high temperatures are prevented by sous-vide cooking (Diaz et al., 2011). The vacuum-sealing process helps retain volatile flavour compounds, preventing them from escaping during cooking (Bhattacharya et al., 2024).

Despite all these advantages, sous-vide cooking has some disadvantages. Because the sous-vide technique uses lower temperatures than traditional methods, pathogens are not always eliminated. Improper cooking, processing, and storage conditions can increase the risk of microbial contamination. Furthermore, if precise temperature control is not achieved and the products are not rapidly cooled after cooking, spore-forming bacteria can survive. While vacuum packaging provides significant advantages, it also provides a suitable environment for anaerobic pathogen growth. There is also a risk of harmful chemicals leaking into the food from the plastic materials used in vacuum packaging (Bhattacharya et al., 2024).

SOUS-VIDE APPLICATIONS FOR AQUATIC PRODUCTS

The sous-vide technique is used to cook a variety of foods. Scientific research exists on its use in various foods. For example, some studies have examined its effects on the quality of foods such as beef, chicken, pork, salad, lamb, and meatballs (Vaudagna et al., 2002; Wang et al., 2004; Diaz et al., 2008; Leykane et al., 2010; Roldan et al., 2015; Can and Harun, 2015). However, the number of studies on seafood is limited.

Seafood, due to its high-water activity and neutral pH, is among the foods that spoil quickly. These characteristics provide an environment for bacterial growth. Furthermore, their high free amino acid content reduces their shelf life. However, with the application of sous vide technology, vacuum packaging allows for a longer shelf life than traditional methods (Zakrzewski et al., 2023; Lovaszova et al., 2024). This method is important for fish, as it extends the shelf life of seafood while preserving its freshness and appearance. Gonzales-Fandos et al. (2004) conducted sensory and microbiological analyses on rainbow trout (*Oncorhynchus mykiss*) after sous-vide cooking at 90°C for 3.3 and 1.04 minutes and at 70°C for 5.18 minutes, and storing at 2 and 10°C. They determined that heat treatment of the core at 90°C for 3.3 minutes was the most effective method for extending shelf life. Another study reported that 15 minutes at 90°C was the most effective method for extending the shelf life of salmon slices cooked sous-vide at different temperature-time combinations (5 min/65°C, 10 min/90°C, and 15 min/90°C), but sensory properties were not optimal under these conditions (Gonzales-Fandos et al., 2005). Garcia-Linares et al. (2004) investigated the effects of fish fat content on

microbial safety during sous-vide cooking and determined that the fat content of fish should be considered when creating adequate temperature/time combinations to ensure fish microbial quality and shelf life. It has been reported that seerfish steaks, for which the sous-vide application was developed by optimizing the process parameters, can be stored at 3°C for up to 65 days (Singh et al., 2016).

Cooking at high temperatures causes myofibrillar proteins to shrink and reduce their water-holding capacity. However, sous-vide cooking preserves the secondary structure of proteins better than traditional methods. Wan et al. (2019) demonstrated that sous-vide cooking in sea bass fillets was effective in preserving the secondary structure of proteins. Long-term cooking at low temperatures reduces thermal degradation of proteins and lipids (Zvadlav et al., 2020). Since myofibrillar proteins and collagen are sensitive to high temperatures, these proteins must be protected to ensure tenderness and juiciness in fish (Kathuria et al., 2022). Sous-vide processing significantly increased the structural stability, firmness, and flexibility of muscle fibers in tilapia fillets, reduced nutrient loss, enriched flavor, and mitigated the effects on taste and fishy odor (Yang et al., 2023).

Sous-vide cooking prevents microbial growth in seafood and extends shelf life. A decrease in the total viable count has been reported in seerfish steaks after sous-vide cooking (Singh et al., 2016). Hand-picked crab meat poses a risk of microbial contamination from processors and the processing environment. No microorganisms were observed to grow on crab lump meat when cooked sous-vide, regardless of the cooking regimen (Olatunde and Benjakul, 2021). Conventionally cooked mussels (90°C-10 min) have a shelf life of approximately 14 days, while mussels cooked sous-vide (85°C-10 min) and chilled have a shelf life of approximately 21 days. Since bivalve mollusks, as filter feeders, can accumulate microorganisms, including pathogens, from seawater, the possibility of producing pasteurized mussels and new mussel-based ready meals with extended shelf life is an important innovation for producers and the preservation of fresh appearance and nutritional value, as well as the prevention of product loss, is gaining its value (Bongiorno et al., 2018).

The quality of fish cooked sous-vide depends on the temperature-time combination. A study using salmon sous-vide reported that lower time-temperature parameters resulted in less nutrient loss, but it was not suitable for microbiological quality. While no microbiological limits were exceeded, this method should be used with extreme caution when using low-temperature, short-time cooking (Głuchowski et al., 2020). Temperature and duration also affect lipid oxidation in seafood. Cropotova et al. (2019) determined that lipid oxidation in Atlantic mackerel accelerated with increases in temperature and duration.

CONCLUSIONS

While seafood is a highly nutritious food, it is also highly perishable. The flesh of seafood provides a suitable environment for microorganisms to grow. Therefore, if not processed and stored appropriately after catching or harvesting, its quality can deteriorate rapidly. The sous-vide technique is a suitable method for cooking seafood, as it reduces moisture, nutrient, and flavor losses while also preventing the growth of spoilage-causing aerobic bacteria. These beneficial effects of sous-vide cooking on seafood have been demonstrated in various studies. However, further research is needed to fully understand and optimize this technique. Processing parameters significantly affect both the quality and safety of the final product. Therefore, different processing conditions should be investigated across a range of seafood products. Moreover, additional efforts are required to ensure product safety. Since spore-forming bacteria may survive the cooking process, comprehensive studies should address not only cooking parameters but also rapid cooling, cold storage, and serving stages.

FISH SPECIES SETTLING IN AN ARTIFICIAL REEF MODEL CREATED FROM FALLEN CONCRETE PIERS OF PIPES INTAKE FROM THE SEA IN KONYAALTI, ANTALYA

Mehmet Gökoğlu

Akdeniz University Fisheries Faculty, Antalya, Türkiye

Corresponding author e-mail: gokoglu@akdeniz.edu.tr

ABSTRACT

At Konyaaltı Beach, Antalya, HDP pipes were laid approximately 400 meters offshore to receive water from the sea. Concrete piers were used for weighing these pipes. Many of these piers fell due to movement and displacement of the pipe during winter storms. During our scuba dives in this region, the concrete piers that fell from the pipe were retrieved from where they fell and two artificial reef prototypes were built at a depth of 20 and 21 meters. This research aims to identify the fish species that settle in these artificial reef prototypes. The fish that settle in the artificial reef models belong to the families Holocentridae, Serranidae, Scorpaenidae, Sigaenidae, Muraenidae and Monacanthidae. Our research indicates that the Red Sea migrants predominate in terms of the number of families and species of fish occupying the artificial reefs.

INTRODUCTION

The term "*reef*" generally refers to any naturally occurring structure that lies beneath the water surface (Ahana et al., 2010). As the name suggests, *artificial reefs* are man-made structures that are typically placed on the seabed or intentionally submerged into aquatic environments. The primary aim of artificial reefs is to provide new habitats for marine organisms, enhancing and supporting marine ecosystems (Anon, 2024).

The construction of artificial reefs dates to ancient times. For instance, approximately three thousand years ago in the Mediterranean, stones discarded from tuna fishing traps known as *Tonnara* gradually accumulated and acted as fish aggregating structures—considered early forms of artificial reefs (Riggio et al., 2000). Around 250 BC, during the First Punic War, Romans reportedly constructed an artificial reef using stones and building materials to blockade Lilybaeum harbor against Carthaginians, and they installed poles in the canals using large timber and anchors. Similarly, it has been reported that the Persians built an artificial reef at the mouth of the Tigris River to block Arab pirates (Anon, 2025).

Modern artificial reefs are designed to mimic the ecological characteristics of natural reefs through careful planning and material selection. These structures provide shelter, food, and breeding grounds for various marine organisms such as fish, crustaceans, mollusks, algae, and plants thereby creating vibrant, biodiverse marine ecosystems. Materials used in artificial reef construction include concrete and steel, decommissioned ships, sunken objects, and specially designed reef modules all promoting the attachment and settlement of marine life (Anon, 2024).

The primary purposes of artificial reefs include marine habitat restoration, biodiversity enhancement, fisheries management, recreational opportunities, coastal protection, and erosion control. Strategically placed in areas where natural habitats have been degraded or lost, artificial reefs aid in the revitalization of marine ecosystems. They also facilitate the formation of various links within the food chain, triggering dynamic biodiversity development and increasing overall productivity (Anon., 2024).

These structures additionally act as *Fish Aggregating Devices (FADs)* by attracting fish to specific areas, making them easier to locate and harvest. This reduces fishing pressure on natural populations and supports sustainable fisheries management (Kasım, 2010). Artificial reefs are often positioned near shorelines to serve as natural wave barriers that reduce coastal erosion. By dissipating wave energy, they help protect coastal infrastructure from storm surges (Anon, 2024).

Beyond their ecological benefits, artificial reefs also offer recreational opportunities for scuba divers, snorkelers, and tourists. By establishing vibrant underwater ecosystems, they attract marine enthusiasts and contribute to local tourism, thereby supporting the coastal economy. They also promote and support sport fishing activities (Anon., 2024).

In a related study, live coral cover was recorded at 18.75% on artificial reefs, compared to 23.8% on nearby natural reefs. However, the abundance of fish and associated organisms was significantly higher on artificial reefs (28.13%) than on natural reefs (6.9%). This difference is attributed to the increased shelter provided by artificial structures. Furthermore, artificial reefs allow for vertical use of the water column, enabling more organisms to settle and inhabit the area (Kumar & Raghunathan, 2010).

MATERIAL AND METHOD

In this study, artificial reef material consisted of concrete weights that had fallen from an HDP pipeline, which had been previously installed to transport seawater from Konyaaltı Beach to a city aquarium located inland (Fig. 1). The pipeline extends approximately 400 meters offshore. The T-shaped open end of the pipeline had shifted roughly 50 meters west due to entanglement with fishing nets and the impact of winter storms, resulting in the dislodgement of several concrete weights.

During scuba dives conducted in April 2025, these weights were collected from the seabed and used to construct two prototype artificial reefs at depths of approximately 20–21 meters (Fig. 1, 2). No natural reefs are present in the area, and the seabed is characterized by sandy and sandy-gravel substrates.

Scuba dives were conducted at 2–3-day intervals to monitor the fish species that settled on the prototype reefs. Photographic and video documentation was carried out using GoPro Hero 8 and GoPro Hero 13 action cameras. The diversity of species on the reefs was assessed using the Shannon Diversity Index (H'), calculated as follows:

$$H = -\sum [(p_i) * \log(p_i)]$$

H = Shannon Diversity index

P_i : It corresponds to the abundance of an individual species with respect to the others.

$$P_i = n/N$$

n = No of individuals in a given species

N = The total number of individuals in a community

$$Eh = H / \ln(S)$$

S = Total number of unique species

Figure 1. Reef made from fallen concrete legs of HDP pipe.

Figure 2. Second artificial reef at Konyaaltı Beach

RESULTS AND DISCUSSION

In this study, no foreign materials were introduced into the marine environment, and no harm was caused to marine organisms. The prototype artificial reef was constructed using concrete weights that had previously detached from the HDP pipeline already present on the seafloor.

The first species to colonize the prototype reef was *Sargocentron rubrum*, commonly known as the Redcoat Squirrelfish and locally referred to as the “Nylon Fish” in the Antalya region. Individuals of this species settled on the reef in schools and continued to inhabit the area. Observations revealed a uniform size distribution among individuals (Fig. 3).

Sargocentron rubrum is a non-native species to the Mediterranean. Its natural distribution includes the Western Pacific, Indian Ocean, and Red Sea. It entered the Mediterranean via the Suez Canal, classifying it as a Lessepsian migrant (Kabaklı & Ergüden, 2018). This species, which prefers rocky crevices and caves at depths ranging from 1 to 84 meters, has tough scales and can reach up to 32 cm in length (usually around 27 cm). Although it has low commercial value as a food fish, it is considered valuable in the aquarium trade (Golani et al., 2021).

Five additional fish species from the Serranidae family were identified on the reef:

- *Epinephelus aeneus* (White Grouper)
- *Epinephelus costae* (Goldblotch Grouper)
- *Epinephelus marginatus* (Dusky Grouper)
- *Mycteroperca rubra* (Mottled Grouper)
- *Serranus scriba* (Painted Comber)

These species are native to the Mediterranean and typically inhabit rocky substrates (Golani et al., 2006). Among them, the Dusky Grouper (*E. marginatus*) is a protected species in Turkey. Its harvesting is completely prohibited, and it is listed as *Vulnerable (VU)* on the IUCN Red List.

Table 1. Fish species settled in artificial reefs and calculation of the Shannon Diversity Index

Family	Species	Frequency	Pi	Ln (Pi)	Pi (lnpi)
Holocentridae	<i>Sargocentron rubrum</i>	200	0.833	-0.182	0.15
Serranidae	<i>Epinephelu aeneus</i>	3	0.013	-4.342	0.06
	<i>Epinephelus</i>	2	0.008	-4.828	0.04
	<i>marginatus</i>	2	0.008	-4.828	0.04
	<i>Epinephelus costae</i>	4	0.017	-4.075	0.07
	<i>Mycteroperca rubra</i>	4	0.017	-4.075	0.07
	<i>Serranus scriba</i>				
Scorpaenidae	<i>Pterois miles</i>	7	0.029	-1.238	0.04
Siganidae	<i>Siganus rivulatus</i>	10	0.042	-3.170	0.13
Monacanthidae	<i>Stephanolepis diaspros</i>	3	0.012	-4.423	0.05
Muraenidae	<i>Muraena helena</i>	1	0.004	-5.521	0.02
				H	0.67
				E_H	0.37

Figure 3. *Sargocentron rubrum* settled on the prototype artificial reef

Another species observed on the artificial reef was *Siganus rivulatus*, belonging to the **Siganidae** family. Commonly known in the region as the “White Rabbitfish,” this species was frequently seen on the reef in schools. Primarily herbivorous and feeding on algae, these fish were sometimes observed venturing away from the reef or exhibiting hiding behavior between the concrete blocks during scuba dives. Originating from the Red Sea, this species is also one of the Lessepsian migrants that later entered the Mediterranean (Çiftçi et al., 2022).

Another Red Sea-origin species recorded was *Stephanolepis diaspros*, commonly known as the “Filefish,” belonging to the **Monacanthidae** family. Typically inhabiting rocky and sandy substrates (Metin & Akyol, 2021), this fish was among the first to settle on the artificial reef. During every scuba dive, two individuals of this species were consistently encountered on the reef.

Moray eels (*Muraena helena*) generally inhabit rocky environments, such as beneath rocks, in crevices, and inside underwater caves, and are mostly active at night (Kaya & Özen, 2022). The moray eel was also one of the species observed to have settled on the artificial reef. The same individual was frequently encountered during scuba dives, indicating residency.

CONCLUSIONS

In addition to the species listed above, other fish were observed around and on the reef. However, these species appeared to be temporary visitors rather than resident reef dwellers. Only the species that were consistently observed and identified as reef residents during the scuba dives are reported in this study (Table 1). A total of 10 fish species from 6 different families were found to have settled on the reef. Notably, 4 of these families are of Red Sea origin. The Shannon Diversity Index for the reef community was calculated as 0.67, indicating low species diversity and the dominance of a single species within the community.

EXPLORING THE AVAILABILITY OF BULGARIAN PLANT GENETIC RESOURCES IN THE INTERNATIONAL CROP NETWORKS

Nikolaya Velcheva

Agricultural Academy, Institute of Plant Genetic Resources – Sadovo, Bulgaria

Corresponding author e-mail: nikolaya_velcheva@abv.bg

ABSTRACT

Ex situ collections are backup copy of diversity and thus its conservation is guaranteed. One of the most widely discussed topics in current ecological politics is concerning the open access to the plant genetic resources by all stakeholders. EU countries are acting together to ensure the access to the gene fund as a public resource responsible for food security and with critical importance for the sustainability of the agrifood system. IPGR-Sadovo maintains the richest genebank collection in Southeast European region and it is nominated as a national focal point in the European search catalogue for plant genetic resources – EURISCO (<http://eurisco.ecpgr.org>). The electronic network includes passport information according to FAO/Bioversity descriptors. The study aims to present the status of Bulgarian National Inventory in EURISCO. The standard of the data allows the development to be evaluated and described using passport descriptors: number of accessions, genus, species, common crop name, collecting number, geographic coordinates (latitude, longitude, elevation), collecting and acquisition date, FAO institute code, biological status of accession (wild, landraces, breeding material, advanced cultivar), collecting source (wild or cultivated habitat, research organization or genebank). The results show high diversity level between data recorded for each descriptor and crop. The published *ex situ* accessions in EURISCO from Bulgaria are 71,239 in total and belong to 532 genera and 1,927 plant species. The national collection is the 7th largest in Europe with a share of 3.4% after Great Britain, Russia, Germany, Ukraine, Poland and Spain. The Information System for documentation of Bulgarian genebank implements an export from the database to EURISCO. A convenient and flexible architecture of the application has been developed, which includes intelligent modules to facilitate the data transfer process. Through EURISCO, the data for Bulgarian collection is presented in the other international information networks such as, AEGIS, FAO WIEWS and GENESYS. The research work was carried out under the IS-PGR-SADOVO project, supported from the Bulgarian National Science Fund.

Keywords: Accession, Plant databases, Passport descriptors, European collaboration, *Open access*.

INTRODUCTION

One of the biggest challenges in the modern world is ensuring food security. An important step in this direction is increasing the productivity of crops in conditions of climate change and reduced inputs, while ensuring sustainable development and protection of natural resources. National genebanks offer diverse collections of locally adapted crops which can support farmers' climate resilience, nutritional security and economic innovations, yet are often overlooked in crop adaptation strategies. Across much of the world, national genebanks are unknown to farmers, or poorly connected to breeders (Heaton et al., 2025).

Ex situ collections are backup copy of diversity and thus its conservation is guaranteed. One of the most widely discussed topics in current ecological politics is concerning the *open access* of plant genetic resources by all stakeholders (Pillinget al., 2020).

EU countries are acting together to ensure the access to the gene fund as a public resource responsible for food security and with critical importance for the sustainability of the agri-food system (Brink and Hintum, 2020).

Each country is responsible for preserving its gene pool as a national treasure – a resource with biological and economical value, initial material for the creation of varieties that meet the requirements of current and future generations. Enhancing the efficiency of genebanks requires implementing a quality management system that ensures data transparency, as well as the documentation and standardization of processes (Engels and Ebert, 2021; Hintum et al., 2025).

IPGR-Sadovo maintains the richest seed genebank collection in Southeast European region and it is nominated as a National Focal Point in the European search catalogue for plant genetic resources – EURISCO (Dias et al., 2012; Weise, 2021).

The study aims to present the status of Bulgarian National Inventory in EURISCO.

MATERIAL AND METHOD

The National Genebank, located in the Institute of Plant Genetic Resources, part of the Agricultural Academy, is the main center for the long-term conservation of the plant gene pool of Bulgaria and as such is an active partner in the international system for the preservation of biodiversity. It has been nominated by the European Program on Plant Genetic Resources (ECPGR) as a responsible center for Bulgaria, which guarantees the participation of our country in the European Electronic Catalogue (EURISCO) and in the construction of the virtual European Genebank - AEGIS (Hintum et al., 2021). IPGR is committed to the implementation of the Convention of Biological Diversity; The European Strategy for Plant Genetic Resources (ECPGR, 2021) follows the EU's Environmental Policies and the Global Sustainable Development Goals. This commitment emphasizes the importance of the Institute in the conservation of plant diversity at the national and international level.

The Information Centre for Plant Genetic Resources in Sadovo was created in 1982. It was completely renovated and the National GeneBank Information System for plant genetic resources is established. The Information Centre works according to the international standard for documentation of FAO/Bioversity (2017) for *ex situ/on farm* conservation of plant genetic resources and FAO/Bioversity (2022) for *in situ* preservation of crop wild relatives. It is following the priorities for *open access* to the genebank collections in Europe, for available food plants databases as a bioresource for crop breeding and agriculture, and for maintaining a global system for free germplasm exchange between all users (Brink and Hintum, 2020; ECPGR, 2021).

The electronic database of Bulgarian genebank contains the following passport information: taxonomic description, catalogue number, date of acquisition, country of origin, donor of the sample, collection site, ecology-geographical characterization, biological status, type of storage: long-term (base collection), medium-term (exchange collection), short-term (working collection), *in vitro*, cryo-conservation, field collection, botanical garden and agroecological data for *in situ* preservation of crop wild relatives.

The Genebank Standards for Plant Genetic Resources for Food and Agriculture in the conservation process is followed (FAO, 2013).

The IS-PGR-SADOVO project supports the establishment of quality standard for *ex situ/in situ/on farm* storage, in accordance with the Operational Guide for the Bulgarian Genebank, approved by the ECPGR Management Committee (ECPGR, 2023).

The project focuses on the development and implementation of innovative technologies for the management and storage of plant genetic resources in the Bulgarian genebank. The main goal is to optimize the quality and efficiency of the processes in the National Genebank by using intelligent tools. The project significantly improves the management, storage and access to collections, thereby supporting the long-term conservation of the plant gene pool as a public resource used by the scientific community, breeding companies and other users.

RESULTS AND DISCUSSION

EURISCO provides information about more than 2 million accessions of plants and their crop wild relatives, preserved *ex situ* by about 400 institutes. It is based on a network of National Inventories of 43 member countries and represents an important effort for the preservation of world's agrobiological diversity by providing information about the large genetic diversity kept by the collaborating institutions (Fig. 1, 2).

Figure 1, 2. Statistical overview in EURISCO

The analysis shows that Bulgaria maintains the richest *ex situ* collection in the South-Eastern Europe as the 7th largest in Europe with a share of 3,40% after The Great Britain, Russia, Germany, Ukraine, Poland and Spain.

The results show high diversity level between data recorded for each descriptor and crop. The published accessions in EURISCO from Bulgaria are 71,239 in total and belong to 532 genera and 1,927 plant species (Table 1). The highest number of accessions are from genera *Triticum*, *Hordeum*, *Zea*, *Phaseolus*, *Secale*, *Avena*, *Vicia*, *Capsicum*, *Pisum* (Fig. 3).

Table 1. Holding institutes of the Bulgarian National Inventory

FAO CODE	Holding institute name	Number of accessions	Accessions of Bulgarian origin
BGR001	Institute for Plant Genetic Resources, Sadovo	66,798	17,316
BGR005	Institute of Rose and Essential-oil Plants, Kazanlak	563	4
BGR007	Institute of Maize, Kneza	19	19
BGR015	Institute of Forage Crops, Pleven	2	2
BGR029	Dobrudja Agricultural Institute, General Toshevo	3,857	1,829
Total number		71,239	19,170

Figure 3. Genera with the highest number of accessions in the Bulgarian Collection

Background crop wild relatives represent a valuable resource for ensuring food security. Although they are negatively affected by the loss of habitats due to climate change and land use change, they are underrepresented in conservation programmes. The establishment of genetic reserve networks has been put forward as an approach to protect crop wild relatives (Bönisch et al., 2025).

In addition to *ex situ* data the EURISCO infrastructure has recently been extended for the management of *in situ* data. Bulgaria is from the pilot countries which have already provided data on *in situ* crop wild relatives populations. The status includes passport data for 243 wild populations (20 populations uploaded to EURISCO in 2023 and 223 populations in 2024) as a result from monitoring of local sites (Fig. 4).

The National Genebank Information System is following the EU descriptors for documentation of plant genetic resources. Through the created module the data is exporting according to the standard and it is uploading to the EURISCO *ex situ/in situ* intranet. A convenient and flexible architecture of the application has been developed, which includes intelligent tools to facilitate the staff and to improve the genebank management (Fig. 5).

The IS-PGR-SADOVO project activities optimize the EURISCO transfers and increases the quality of data for conserved plant genetic resources. The Genebank Information System is guaranteeing the functionality of documentation as well as the open access to the plant gene pool to all stakeholders, in accordance with internationally signed documents, such as the International Treaty (ITPGRFA, 2009) and the Nagoya Protocol (CBD, 2011). The automatic EURISCO transfer module has a scientific and social impact with its functions to serve a large number of consumers at regional, national and international level. One of the most

important impacts is that the National Seed Genebank is recognized as one of the richest collections in Europe.

Through EURISCO the information about the Bulgarian National Inventory is accessible in other international databases, such as FAO WIEWS (2020) and GENESYS (2015).

The exploring the availability of Bulgarian plant genetic resources in the international crop networks shows that the enrichment of collection and all information activities are directed to increasing the open access to genebank accessions assisting the priority topics:

- ✿ Close interaction with scientific and educational centers in Bulgaria and abroad;
- ✿ Collection of existing old varieties and on farm conservation;
- ✿ Study and monitoring of new territories for in situ conservation of crop wild relatives;
- ✿ Creation of demonstration collections with educational and practical purposes (with wild species and traditional varieties);
- ✿ Preparation of a plan for better interaction between biodiversity conservation, crop breeding and agriculture to establish good practices.

CONCLUSIONS

International crop networks provide *open access* to the potential users of conserved genotypes according to the principles of the International Treaty on Plant Genetic Resources for Food and Agriculture and the implementation of the Nagoya Protocol on equitable distribution of their benefits.

Electronic portals eliminate the restrictions associated with distant locations of genebanks and improve coordination between researchers in the area of plant genetic resources. The European cooperation allows for better coordination of activities regarding germplasm registration, conservation, characterization, evaluation, documentation and use.

The National Genebank Information System is following the FAO/Bioversity descriptors for documentation of plant genetic resources. Through the created module the data is exporting according to the standard and it is uploading to the EURISCO *ex situ* / *in situ* intranet. A convenient and flexible architecture of the application has been developed, which includes intelligent tools to facilitate the staff and to improve the genebank management.

Bulgaria with its high ecogeographic diversity and extreme production conditions is a valuable international partner in climate change mitigation research projects.

ACKNOWLEDGEMENTS

The research work was carried out under the project IS-PGR-SADOVO “Intelligent system for managing Bulgarian plant gene pool, conserved in the genebank of IPGR-Sadovo” with the financial support of the Ministry of Education and Science, Contract number KP-06-H86/9/09.12.2024 of Bulgarian National Science Fund.

ABSTRACT

Pinus brutia Ten. (Turkish pine), widely distributed along the eastern Mediterranean and Aegean coasts, plays a vital ecological role in afforestation projects due to its windbreaking and soil-stabilizing properties. Beyond its ecological functions, *P. brutia* also holds significant economic value through its resin, timber, and seeds, which are used in various industries such as construction, furniture, pastry production, and traditional medicine. In recent years, the global emphasis on sustainability and waste valorization has directed attention to the potential applications of forestry by-products. Among these, the bark of Turkish pine—typically considered a waste material has emerged as a promising source of oligomeric proanthocyanidins (OPCs), polyphenolic compounds known for their potent antioxidant activity.

In this study, OPC-rich extracts were obtained from Turkish pine bark through ethanol (PBET) and ethanol-water (PBAS) based extractions. The radical scavenging capacity was evaluated using DPPH and ABTS assays. The results revealed that the OPC extract exhibited strong antioxidant potential, with IC₅₀ values of 6.92±0.39 - 8.17±0.56 µg/mL (DPPH) and 6.15±0.54 - 7.20±0.32 µg/mL (ABTS), comparable as better than standard antioxidants such as BHA (19.70±0.25 µg/mL DPPH and 12.80±0.50 µg/mL ABTS) and α-tocopherol (38.70±0.32 µg/mL DPPH and 33.20±0.25 µg/mL ABTS) These findings highlight the significant radical scavenging ability of *P. brutia* bark extracts, which is attributed to the presence of hydroxyl-rich flavan-3-ol oligomers.

This study suggests that Turkish pine bark, an abundant and underutilized forestry residue, may serve as a valuable bioresource in nutraceutical, cosmetic, or pharmaceutical applications. Future research may focus on isolating specific OPC fractions and evaluating their biological activities in vivo. The integration of such natural waste-derived antioxidants into commercial products may contribute to both environmental sustainability and human health.

Keywords: *Pinus brutia* Ten., Turkish Pine, Bark, Radical scavenging activity

INTRODUCTION

Pinus brutia Ten. which known as Turkish pine is the one of the most common tree species in Mediterranean basin (Sheffer et al., 2012). *Pinus brutia* Ten. (Turkish pine), a characteristic tree of the Eastern Mediterranean ecosystem, holds great ecological and economic significance. In the furniture sector it's preferred due to good quality of its timber, and in the construction sector also Turkish pine's importance is remarkable (Pantelas, 1986). Its resin and seeds also have its places at pastry and adhesive industry (Pizzi, 1982; Gönültaş et al., 2018; Dunky, 2021). *Pinus brutia*'s resin and essential oils from its different parts were studied and showed important in vitro results in some known bioactivity determiner (Loizzo et al., 2008; Ulukanli et al. 2014; Chammam et al., 2024).

Its bark, generally considered as a forestry by-product, is rich in oligomeric proanthocyanidins (OPCs), a class of polyphenolic compounds formed mainly from catechin and epicatechin subunits (Hemingway, 1989; Ucar et al., 2013). These compounds are known for their potent antioxidant activities, attributed to their hydroxyl-rich structure capable of scavenging free radicals (Pedan et al., 2017; Luca et al., 2020).

Previous studies on *Pinus pinaster* (French maritime pine) bark extracts, such as the commercial Pycnogenol®, have revealed diverse health benefits including antioxidant, anti-inflammatory, and cardioprotective properties (Nattagh-Eshtivani et al., 2022; Park et al., 2023) While research on *P. pinaster* is extensive, investigations focusing on *P. brutia* bark remain comparatively limited. Recent *in vitro* studies demonstrated that *P. brutia* bark extracts possess high phenolic content and strong radical scavenging activity, suggesting a similar or even greater potential compared to other well-studied species (Taş-Küçükaydın, 2023).

This study aims to evaluate the radical scavenging activities of ethanol and ethanol-water extracts of *P. brutia* bark, using DPPH and ABTS assays. Results are compared with standard antioxidants (BHA, α -tocopherol) and discussed in the context of literature data on other natural polyphenolic sources. The radical scavenging activity on DPPH and ABTS assays was chosen for checking the effect of scavenging in lipophilic and hydrophilic environment and due to their results generally associated with anti-aging, cell wall's oxidative stress relieving effects, and suitability with cosmetic, nutraceutical, and pharmaceutical applications (Gulcin, and Alwasel, 2023).

MATERIAL AND METHOD

Plant Material

Pinus brutia bark samples were collected from natural populations in the Muğla region, Turkey. The samples were dried under shade, powdered, and stored at 4 °C until analysis.

Extraction Procedure

Two extraction systems were applied: PBET: ethanol extraction, and PBAS: ethanol-water %50-50 extraction. Powdered barks were extracted with the solvent system for 24 h under at room temperature. Filtrates were concentrated under reduced pressure and lyophilized.

Antioxidant Activity Assays

DPPH and ABTS radical scavenging assays were carried out with extract concentrations ranging from 2–50 μ g/mL. Absorbances were measured at 517 nm (DPPH) and 734 nm (ABTS). Radical scavenging capacity was expressed as IC₅₀ values. BHA and α -tocopherol were used as reference standards (Blois, 1958; Re et al., 1999; Tel et al., 2012; Çayan et al, 2014).

RESULTS AND DISCUSSION

The ethanol (PBET) and ethanol-water (PBAS) extracts of *P. brutia* bark exhibited strong antioxidant activities (Table 1). Results were found as respectively IC_{50} : 6.92 ± 0.39 $\mu\text{g/mL}$ and 8.17 ± 0.56 $\mu\text{g/mL}$ for DPPH, and IC_{50} : 6.15 ± 0.54 $\mu\text{g/mL}$ and 7.20 ± 0.32 $\mu\text{g/mL}$ for ABTS assays. These values indicate superior antioxidant potential compared to standard antioxidants BHA (IC_{50} : 19.70 ± 0.25 $\mu\text{g/mL}$ for DPPH and IC_{50} : 12.80 ± 0.50 $\mu\text{g/mL}$ for ABTS) and α -tocopherol (IC_{50} : 38.70 ± 0.32 $\mu\text{g/mL}$ for DPPH and IC_{50} : 33.20 ± 0.25 $\mu\text{g/mL}$ for ABTS).

The results are consistent with previous studies on *P. pinaster* bark extracts, particularly Pycnogenol®, which exhibited IC_{50} values in the range of 5–10 $\mu\text{g/mL}$. This suggests that *P. brutia* bark is comparable or even superior in radical scavenging activity. Furthermore, in the studies on grape seed proanthocyanidins (IC_{50} : 10–20 $\mu\text{g/mL}$) showed weaker activities than *P. brutia* extracts, highlighting the promising antioxidant potential of this species (Habib et al., 2022).

The high activity can be attributed to hydroxyl-rich flavan-3-ol oligomers present in *P. brutia* bark, which facilitate electron and hydrogen atom donation (Godos et al., 2024). Therefore, *P. brutia* bark, commonly regarded as forestry waste, represents a potential bioresource for nutraceutical, cosmetic, and pharmaceutical applications.

Table 1. Antioxidant activities of the fractions from *P. brutia*

Samples / Standards	Antioxidant activity (IC_{50} $\mu\text{g/mL}$)	
	DPPH assay	ABTS assay
PBET	6.92 ± 0.39	6.15 ± 0.54
PBAS	8.17 ± 0.56	7.20 ± 0.32
BHA	19.70 ± 0.25	12.80 ± 0.50
α -tocopherol	38.70 ± 0.32	33.20 ± 0.25

CONCLUSIONS

This study demonstrated that oligomeric proanthocyanidin rich alcohol and alcohol-water extracts of *Pinus brutia* bark exhibit strong antioxidant properties, as revealed by low IC_{50} values in DPPH and ABTS assays. These values were significantly better than synthetic (BHA) and natural (α -tocopherol) standards. The findings suggest that *P. brutia* bark, an abundant forestry residue in Turkey, can serve as a valuable bioresource. Future work should focus on advanced characterization of OPC fractions using chromatographic and spectroscopic techniques, assessment of in vivo activities, and exploration of industrial applications for nutraceuticals and pharmaceuticals.

ABSTRACT

The aim of this research is to provide information about estimating and predicting the vegetable production in Albania until the year 2029 with the hope that the government and stakeholders can design more targeted distribution and investment strategies for more effective agricultural production planning. We have applied the Adams-Bashforth-Moulton method in Verhulst growth model. This method is a multistep method which consists of Adams-Bashforth method as predictor and Adams-Moulton method as corrector. Using vegetable production data for the period 1998-2024 obtained from the Institute of Statistics in Albania, the model was initialized using the fourth-order Runge-Kutta method to generate four initial values which were then substituted into the fourth-order Adams-Bashforth predictor equation. The Adams-Moulton method can provide a fairly accurate solution and is completed iteratively. Calculations and comparisons of predicted and actual data of vegetable production are done using Matlab and Excel software packages for the Verhulst growth model and numerical method in the study. The simulation results show that every year the amount of production increases and for the period 1998-2024 using both Verhulst model and numerical method we have coefficient of determination=0.98 and correlation coefficient=0.99. These results show that Verhulst model and Adams-Bashforth-Moulton method can be used to describe and predict the vegetable production in Albania. This research can serve as a foundation for more effective agricultural production planning and supply chain optimization in Albania.

Keywords: Adams-Bashforth-Moulton-method, Vegetable production, Fourth-order Runge-Kutta method, Numerical method, Verhulst model.

INTRODUCTION

Albania is a small country with plenty of opportunities for vegetable production. Vegetables are edible parts of herbaceous plants planted in the ground such as peppers, tomatoes, potatoes, eggplants, cucumbers, onions, etc. Due to the favorable geographical position and climate conditions, in Albania can be cultivated great diversity types of vegetables. Nowadays are cultivated more than 30 types of vegetables. The coastal areas are the most favorable areas of Albania for agricultural production, with fertile soils and relatively good access to the national road system. Most of the country's vegetable production is concentrated in the western part of the country areas such as Lushnje, Fier, Vlore and the region of Korçe in the eastern part of the country. These areas are with mild and relatively short winters providing an ideal climate to produce a wide range of vegetables. Altogether, the small-scale production

structures favor vegetable production, where also greenhouses and irrigation are common to improve production conditions (Bernet and Kazazi, 2012), (Mustafaj et al., 2018).

The importance of vegetables in human nutrition has been known since ancient times, where except for food, some types of vegetables have also been used to treat various diseases. Before the 1990s, the production of vegetables in the country served as food for the population. Much of the production of vegetables was carried out in the coastal areas of Albania because of the favorable climate for vegetable cultivation. For the first time the production of vegetables in the greenhouses was carried out in Divjaka, which was the main area of vegetable cultivation. The main place of vegetables was occupied by tomatoes and cucumbers which were produced in the existing greenhouses. The cultivated areas for the main vegetables have been grown in many parts of the country. This made the production of these vegetables extend and increase. Nowadays, the production of vegetables in the country occupies an important place in the overall agricultural production in supporting the national economy, not only as an inherent culture among Albanian farmers, but also for consumption by the Albanian population. Our country's goal is to orient and secure a sustainable agricultural development. The way to do that is to help increase vegetable production in order to meet the country's needs, minimize imports and also increase export opportunities. So, the support and management of this development gains special importance (Mustafaj et al., 2018), (Xhoxhi and Kongoli, 2023). Agriculture production, in particular vegetable production, has become increasingly competitive in the last decade because of increased cultivation area (including greenhouses), increased yields and improved technologies. The number of collection points and aggregators for trade, especially for the export of vegetables, has increased (Ministry of Agriculture and Rural Development, 2024). In these conditions, accurate prediction of vegetable production is essential for effective planning and decision-making in agriculture.

To estimate the future production of vegetables in Albania, a basic understanding of differential equations is required. Differential equations are a branch of mathematics with many real-life applications. They are used to model a large number of problems in natural sciences, in engineering and in health sciences (Zheng, 2023; Nandeesha et al., 2024; Kapoor and Tothang, 2021; Wahbi et al., 2024; Braun, 2013). Numerical methods have become an effective approach to address complex problems, especially in the field of agriculture. These methods are used to solve mathematical models, providing approximate solutions.

In efforts to make more accurately estimates for vegetable production, we have applied the Adams-Bashforth-Moulton (ABM) method for solving the Verhulst model. This model, which is a nonlinear differential equation, is used in the study to estimate the vegetable production in Albania. The model provides a useful framework for understanding the growth behavior of vegetable production. Determining the solution to a nonlinear ordinary differential equation is often challenging and complex. In one hand, the Verhulst model describes the growth process that is constrained by environmental capacity, which is highly relevant for agricultural commodities such as vegetables. On the other hand, the ABM method is a predictor-corrector numerical integration technique that provides highly accurate estimates. Before applying this method, a one-step method is required to obtain initial values. The one-step method we have used is the fourth-order Runge-Kutta method, which is an early stage method in the study. After the calculation of the initial values by this method, we get the solution of the Verhulst model by ABM method.

Using ABM method, this research not only fills the gap in the use of more sophisticated prediction methods but also offers practical solutions that can be applied in agriculture sector to provide deeper and more relevant insights for stakeholders in this sector.

MATERIAL AND METHODS

THE DATA

The data about the vegetable production are taken from the database of Albanian Institute of Statistics (INSTAT) for period 1998 till 2024 (INSTAT, n.d.). Calculations and comparisons of predicted and actual data of vegetable production are done using Matlab and Excel software packages for the Verhulst growth model and numerical method in the study. Vegetables are healthy and therefore the cultivation of them has always been increasing over the study period, as can be seen from the Figure 1. This figure provides a graphic representation of the progress of the vegetable production in Albania during the period 1998 till 2024, based on the INSTAT data.

Figure 1. Vegetable production (ton) in Albania, 1998-2024

Source: Developed by the authors based on the data from INSTAT (INSTAT, n.d.)

THE VERHULST MODEL

The Verhulst model has been firstly introduced by a Belgian mathematician Pierre François Verhulst. In 1838 he published an article (Verhulst, 1838) in which he proposed a model to describe human population growth, which was called the logistic model (equation) and is presented by equation (1):

$$\frac{dy(t)}{dt} = ry(t) \left(1 - \frac{y(t)}{K} \right) \quad (1)$$

where $y(t)$ is the population size at time t , r is the growth rate and K is the carrying capacity (the maximum size of the population being studied). Nowadays this model is often applied to model the evolution of many systems in agriculture (Dishmema et al., 2023; Latif et al., 2020), in business and economics (Ramos, 2013), biology (Waltman, 1983; Kooi et al., 1998), medicine (Pelinovsky et al., 2020; Daci and Tola, 2021), and demography (Hrytsiuk et al., 2023). In this study we used the Verhulst model noted as in the equation (2):

$$\frac{dV(t)}{dt} = rV(t) \left(1 - \frac{V(t)}{K} \right) \quad (2)$$

where $V(t)$ is the vegetable production (in ton) at time t , r is the growth rate and K is the carrying capacity (the maximum size of the vegetable production). The solution of equation (2) is:

$$V(t) = \frac{KV_0 e^{rt}}{K + V_0(e^{rt} - 1)} \quad (3)$$

The parameters of the specific solution, which are determined using data points of equal time interval $\{(t_0, V_0), (t_1, V_1), (t_2, V_2)\}$ are given by the following formulae (4) and (5):

$$r = \frac{1}{t_1} \ln \left| \frac{V_2(V_1 - V_0)}{V_0(V_2 - V_1)} \right| \quad (4)$$

$$K = \frac{V_1(V_0V_1 + V_1V_2 - 2V_0V_2)}{V_1^2 - V_0V_2} \quad (5)$$

where $t_1 \neq 0$ and $V_0, V_1, V_2 \neq 0$ (Ramos, 2013).

FOURTH-ORDER RUNGE-KUTTA METHOD

This method was invented by mathematicians Carl Runge (1856-1927) and Wilhelm Kutta (1867-1944). The fourth-order Runge-Kutta method is popular and has been used to solve ordinary differential equations problems that require high solution accuracy. This method is an early stage method in our study, because in the calculation only an initial value is needed then we get the solution by ABM method. The most popular form of the fourth-order Runge-Kutta method is presented from the equations (6) and (7) below: (Chapra S. C., 2018)

$$y_{i+1} = y_i + \frac{h}{6}(k_1 + 2k_2 + 2k_3 + k_4) \quad (6)$$

where

$$\begin{aligned} k_1 &= f(t_i, y_i) \\ k_2 &= f\left(t_i + \frac{h}{2}, y_i + \frac{h}{2}k_1\right) \\ k_3 &= f\left(t_i + \frac{h}{2}, y_i + \frac{h}{2}k_2\right) \\ k_4 &= f(t_i + h, y_i + hk_3) \end{aligned} \quad (7)$$

ADAMS-BASHFORTH-MOULTON METHOD (ABM METHOD)

The ABM method is a multi-step method widely used for solving ordinary differential equations. To obtain a solution, multi-step methods require some initial solutions that can be obtained from single-step methods (such as the Euler method, the Heun method, the Taylor series method and the Runge-Kutta method). Multi-step methods are also called predictive-corrective methods because they directly use the predictive and corrective equations in their solutions without first finding the derivatives of the function. The predictive equation, or first equation, is usually used to predict (obtain a first approximation value for y_{i+1}^P), while the corrective equation, or second equation, is usually used to obtain the corrected value (the second approximation to y_{i+1}^C). The most well-known multi-step method is the fourth-order ABM method. The truncation error of the fourth-order ABM method is smaller than that of the second and third-order ABM methods, so it can provide a fairly accurate solution (Chapra and Canale, 2021). The predictor equation of the fourth-order Adams-Bashforth method is presented by the equation (8):

$$y_{i+1}^{(0)} = y_i + \frac{h}{24}(55f_i - 59f_{i-1} + 37f_{i-2} - 9f_{i-3}) \quad (8)$$

After the calculation of $f_{i+1}^{(0)} = f(t_{i+1}, y_{i+1}^{(0)})$, substitute it in the fourth-order Adams-Moulton method which is a corrector equation presented by the equation (9):

$$y_{i+1}^{(l)} = y_i + \frac{h}{24} \left(9f(t_{i+1}, y_{i+1}^{(l-1)}) + 19f_i - 5f_{i-1} + f_{i-2} \right) \quad (9)$$

The procedure conducted in this study for solving Verhulst model equations using the fourth-order ABM method is as follows:

1. Determine the vegetable production rate (r) and carrying capacity (K) based on the real data used in the study (INSTAT, n.d.). It is given the initial value problem of the non-linear differential equation:

$$\frac{dy(t)}{dt} = f(t, y(t)) \quad (10)$$

with initial value $y(t_0) = y_0$, with a fixed step size h and $t_{i+1} = t_i + h$.

2. Define the Verhulst model as a nonlinear differential equation:

$$\frac{dy(t)}{dt} = f(t, y(t)) = ry(t) \left(1 - \frac{y(t)}{K} \right)$$

3. Determine the initial values y_0, y_1, y_2, y_3 , the step size (h), and calculate the initial solution using the fourth-order Runge-Kutta method.
4. Calculate the function values f_i, f_{i-1}, f_{i-2} and f_{i-3} with $i = 3, 4, \dots$ as follows:

$$\begin{aligned} f_{i-3} &= f_0 = f(t_0, y_0) \\ f_{i-2} &= f_1 = f(t_1, y_1) \\ f_{i-1} &= f_2 = f(t_2, y_2) \\ f_i &= f_3 = f(t_3, y_3) \end{aligned} \quad (11)$$

5. Calculate the numerical solution using the fourth-order Adams-Bashforth method given by equation (8):

$$y_{i+1}^{(0)} = y_i + \frac{h}{24} (55f_i - 59f_{i-1} + 37f_{i-2} - 9f_{i-3})$$

6. Calculate $f_{i+1}^{(0)} = f(t_{i+1}, y_{i+1}^{(0)})$ and substitute in the equation (9) to find the numerical solution using the fourth-order Adams-Moulton method.

$$y_{i+1}^{(l)} = y_i + \frac{h}{24} \left(9f(t_{i+1}, y_{i+1}^{(l-1)}) + 19f_i - 5f_{i-1} + f_{i-2} \right)$$

7. Analyze the numerical solution using the ABM method.

RESULTS AND DISCUSSION

We have calculated the parameters of the model and the predicted values from Verhulst model. In this study, the ABM method was applied by solving the problem of predicting the vegetable production in Albania. To implement this method, we followed the following steps:

Step 1. Determine growth rate (r) and carrying capacity (K).

We find the initial value by the fourth-order Runge-Kutta method using equation (2):

$$\frac{dV(t)}{dt} = f(t, V(t)) = rV(t) \left(1 - \frac{V(t)}{K} \right)$$

First we find the growth rate (r) and the carrying capacity (K). These parameters r and K were determined using data points of equal time interval $\{(t_0, V_0), (t_1, V_1), (t_2, V_2)\}$ by the formulae (4) and (5) in Excel using the analytical solution of the Verhulst model and after that they were optimized for best fitting values. The results can be seen in the Table 1.

Table 1. The parameters of the Verhulst model

Parameter estimation	r	K
Value	0.117959239816092	297741.591172142

Source: Developed by the authors

We take $r = 0.117959239816092 \approx 0.12$ and $K = 297741.591172142 \approx 297742$. For $[a, b] = [0, 31]$ ($t \in [a, b]$, $t = 0$ is the year 1998 and $t = 31$ is the year 2029) with many iterations $n = 31$, we have $h = \frac{b-a}{n} = \frac{31-0}{31} = 1$.

Step 2. Define the Verhulst model as a nonlinear differential equation.

The Verhulst model in general form is:

$$\frac{dV(t)}{dt} = rV(t) \left(1 - \frac{V(t)}{K} \right)$$

with the initial value

$$V(t_0) = V_0$$

which in our case it will be:

$$\frac{dV(t)}{dt} = 0.12 V(t) \left(1 - \frac{V(t)}{297742} \right)$$

with the initial value

$$V(t_0) = 21908$$

where $V(t_0) = 21908$ is the vegetable production (ton) at $t = 0$ (year 1998).

Step 3. The Verhulst model was solved to find numerical solutions, so that solutions were obtained using the Runge-Kutta method and the ABM method.

We determine the four initial solutions V_0, V_1, V_2 and V_3 using the fourth-order Runge-Kutta method at intervals $[0, 31]$ with step sizes $h = 1$ and $V_0 = 21908$. The results for only these values V_0, V_1, V_2 and V_3 are shown in the Table 2.

Table 2. The initial solution using Runge-Kutta method

i	t_i	$h = 1$	
		V_i	$\frac{dV(t)}{dt} = 0.12 V(t) \left(1 - \frac{V(t)}{297742} \right)$
0	t_0	21908.00000000	2435.51985490794
1	t_1	24471.623002311	2695.23398523024
2	t_2	27305.538604083	2976.16590333825
3	t_3	30431.087901314	3278.50092888025

Source: Developed by the authors

The initial values $V_0 = 21908.00000000$, $V_1 = 24471.623002311$, $V_2 = 27305.538604083$ and $V_3 = 30431.087901314$ are obtained using Matlab and these values will serve as the initial values to be used in the ABM method.

Step 4. Calculate the values of $f_i, f_{i-1}, f_{i-2}, f_{i-3}$ with $i = 3, 4, \dots, n$ and substitute them in the Verhulst model:

$$\frac{dV(t)}{dt} = 0.12 V(t) \left(1 - \frac{V(t)}{297742} \right)$$

$$\begin{aligned}\text{For } i = 3, f_i &= f_3 = f(t_3, y_3) = f(3, 30431.087901314) \\ &= 0.12 * 30431.087901314 * \left(1 - \frac{30431.087901314}{297742}\right) \\ &= 3278.50092888025\end{aligned}$$

$$\begin{aligned}f_{i-1} &= f_2 = f(t_2, y_2) = f(2, 27305.538604083) \\ &= 0.12 * 27305.538604083 * \left(1 - \frac{27305.538604083}{297742}\right) \\ &= 2976.16590333825\end{aligned}$$

$$\begin{aligned}f_{i-2} &= f_1 = f(t_1, y_1) = f(1, 24471.623002311) \\ &= 0.12 * 24471.623002311 * \left(1 - \frac{24471.623002311}{297742}\right) \\ &= 2695.23398523024\end{aligned}$$

$$\begin{aligned}f_{i-3} &= f_0 = f(t_0, y_0) = f(0, 21908.00000000) \\ &= 0.12 * 21908.00000000 * \left(1 - \frac{21908.00000000}{297742}\right) \\ &= 2435.51985490794\end{aligned}$$

The values of $f_i, f_{i-1}, f_{i-2}, f_{i-3}$ are shown in the Table 2 above. Next, the obtained values are substituted into the Adams-Bashforth method with a step size of $h = 1$.

Step 5. Determine numerical solutions using the Adams-Bashforth method:

$$V_{i+1}^{(0)} = V_i + \frac{h}{24} (55f_i - 59f_{i-1} + 37f_{i-2} - 9f_{i-3}) \quad (14)$$

where V_i is the value of the initial solution to the Runge-Kutta method and f_i is the value of the initial solution using the Verhulsts model.

For $i = 3, V_3 = 30431.087901314, t_{i+1} = t_i + h$, so $t_4 = t_3 + h = 3 + 1 = 4$.

$$V_{3+1}^{(0)} = V_3 + \frac{h}{24} (55f_3 - 59f_2 + 37f_1 - 9f_0)$$

$$\begin{aligned}V_4^{(0)} &= 30431.087901314 + \left(\frac{1}{24}\right) * (55 * 3278.50092888025 - 59 * \\ &2976.16590333825 + 37 * 2695.23398523024 - 9 * 2435.51985490794)\end{aligned}$$

$$V_4^{(0)} = 33869.743799264.$$

Step 6. Determine the numerical solution using the Adams-Moulton method:

$$V_{i+1}^{(l)} = V_i + \frac{h}{24} (9f_{i+1}^{(0)} + 19f_i - 5f_{i-1} + f_{i-2}) \quad (15)$$

where $f_{i+1}^{(0)} = f(t_{i+1}, V_{i+1}^{(0)})$.

For $i = 3, V_3 = 30431.087901314, t_{i+1} = t_i + h$, so $t_4 = t_3 + h = 3 + 1 = 4$ and $l = 0$, we have

$$\begin{aligned}f_4^{(0)} &= f(t_4, V_4^{(0)}) = f(4, 33869.743799264) \\ &= 0.12 * 33869.743799264 * \left(1 - \frac{33869.743799264}{297742}\right) = 3602.02553079620\end{aligned}$$

For $l = 1$ we have,

$$V_{3+1}^{(1)} = V_3 + \frac{h}{24} (9f_4^{(0)} + 19f_3 - 5f_2 + f_1)$$

$$V_4^{(1)} = 30431.087901314 + \left(\frac{1}{24}\right) * (9 * 3602.02553079620 + 19 * 3278.50092888025 - 5 * 2976.16590333825 + 2695.23398523024)$$

$$V_4^{(1)} = 33869.5942302486.$$

Step 7. Now we can calculate the relative error and then compare it with termination criteria $\varepsilon = 6 * 10^{-6}$.

$$\frac{|V_4^{(1)} - V_4^{(0)}|}{|V_4^{(1)}|} = \frac{|33869.5942302486 - 33869.743799264|}{|33869.5942302486|} = 4.41602619683626e - 06$$

From the above results it can be seen that the error is relatively smaller than the termination criteria: $4.4 * 10^{-6} < 6 * 10^{-6}$. Because the error value is smaller than the stopping criterion, namely $\varepsilon = 6 * 10^{-6}$, the calculation can be continued to the steps as before for $i = 4, 5, \dots, 31$, until the 31-st iteration. In the Figure 2 is shown the numerical solution with ABM method for the period 1998-2029.

Figure 2. Numerical Solution with ABM Method

Source: Developed by the authors

This graph also provides insights into the expected changes in the future. These projections can be used to take necessary steps to ensure the enhancement of vegetable production and help farmers and local government to plan better strategies and to address factors affecting the vegetable production in the country. In the Table 3 are presented all the estimation results and the relative error using the ABM method on the Verhulst model for vegetable production in Albania.

Source: Developed by the authors

It can be seen that the vegetable production in Albania is increasing. Value V_i for $i = 4$ to 31 in the Table 3 is the corrector Adam-Moulton method value which states the prediction of the vegetable production. The simulation results show that using both Verhulst model and numerical method we have coefficient of determination=0.98 and correlation coefficient=0.99. The coefficient of determination=0.98 shows a high degree of approximation, which means that the evaluation by the regression equation covers 98% of the variation of the obtained values by

the ABM method. The correlation coefficient=0.99 indicates that the linear relationship between the variables is very strong and positive (in the same direction), which means that as the data values increase, the obtained values by the ABM method increase proportionally. These results show that Verhulst model and ABM method can be used to describe and predict the vegetable production in Albania. Based on numerical simulation results, the estimated vegetable production in Albania in 2025 is projected to be 199412.7407 tons, in 2026 is projected to be 207148.6218 tons, in 2027 is projected to be 214529.8489 tons, in 2028 is projected to be 221530.9265 tons and in 2029 is projected to be 228134.0802 tons. The following Table 4 shows the results of the prediction of vegetable production and the percentage increase in production for the period 2025-2029.

Table 4. Results of the prediction of vegetable production for the period 2025-2029

Year	Production Quantity	Percentage Increase in Production
2025	199412.7407	4.21%
2026	207148.6218	3.88%
2027	214529.8489	3.56%
2028	221530.9265	3.26%
2029	228134.0802	2.98%

Source: Developed by the authors

Table 4 shows that the vegetable production in Albania in 2025-2029 increases every year and the total vegetable production is increased with an average percentage increase of 3.58%. These findings present an optimistic perspective on the future of vegetable production in Albania. In the Figure 3 is shown a comparison of the real data of vegetable production from INSTAT with the approximation results by ABM method and analytic solution of Verhulst model for the period 1998-2029.

Figure 3. Comparison of the real data of vegetable production with ABM method and analytic solution of Verhulst model

Source: Developed by the authors

It is seen that the approximation results for the vegetable production are close to the real data. In this figure are also shown the results of the prediction of vegetable production for the period 2025-2029 by ABM method. This research can serve as a foundation for more effective agricultural production planning and supply chain optimization in Albania. Accurate prediction projections of the study can help the decision makers in designing more effective strategies for the future. This study also shows how numerical methods such as ABM method can be used into applied mathematical modeling to address real-life affairs. Despite the positive results, this study has certain limitations. In the study is assumed a constant growth rate ($r = 0.12$) and carrying capacity ($K = 297742$), which may not reflect the dynamic environmental factors that influence the vegetable production changes over time. In addition, the use of a fixed step size ($h = 1$) may affect the accuracy of the results in case of modeling over a longer time period or under rapidly changing conditions. These limitations highlight the need for more complex and adaptive models in future research.

CONCLUSIONS

This study discusses the application of the ABM method to the Verhulst model. Based on the obtained results in the study, can be concluded that the ABM method can be used to describe and predict the vegetable production in Albania. The results showed that the vegetable production increased every year. This trend suggests that the ABM method successfully describes the positive growth pattern of the vegetable production. This makes the method a valuable tool for agricultural planning. Based on numerical simulation results, it was found that there will be an increase in vegetable production from 2025 to 2029. The estimated vegetable production in Albania in 2025 is projected to be 199412.7407 tons, in 2026 is projected to be 207148.6218 tons, in 2027 is projected to be 214529.8489 tons, in 2028 is projected to be 221530.9265 tons and in 2029 is projected to be 228134.0802 tons. The total vegetable production in the period 2025-2029 is increased with an average percentage increase of 3.58%. The practical implementation of ABM method may require more complex calculations and more computations compared to other simpler approaches. In the future research could be explored the integration of this method with other predictive and numerical techniques in order to enhance prediction accuracy.

ABSTARCT

Pinus brutia Ten., a widely distributed pine species in the Eastern Mediterranean and Aegean regions, is not only ecologically valuable but also a potential source of bioactive compounds such as oligomeric proanthocyanidins (OPCs) found in its bark. This study aimed to evaluate the cytotoxic effects of OPC-rich bark extracts obtained using two different solvent systems (PBET: ethanol and PBAS: ethanol:water) on human lung (A549) and colon (HT-29) cancer cell lines, along with healthy human colon fibroblast cells (CCD18-Co).

The cytotoxic activity of the extracts was assessed using the MTT assay. Cells were treated with increasing concentrations of each extract (0–200 µg/mL) and incubated for 72 hours. IC₅₀ values were determined based on absorbance measured at 540 nm. According to the results, PBAS exhibited the strongest cytotoxic activity on the HT-29 colon cancer cell line with an IC₅₀ of 40.87 ± 0.15 µg/mL, followed by PBET with an IC₅₀ of 95.10 ± 0.07 µg/mL. In both extracts, no cytotoxic effect was observed on the healthy CCD18-Co cell line (IC₅₀ > 200 µg/mL), indicating selective cytotoxicity toward cancerous cells.

These findings suggest that OPCs extracted from *P. brutia* bark have potential as natural, selective anticancer agents. The ethanol:water extract, in particular, demonstrated more potent cytotoxicity, possibly due to enhanced OPC solubility and bioavailability in a mixed solvent system. This activity can be led to consider new studies on characterization of the compounds in the extract and further isolation and detection the more active compounds by enrichment studies. Further studies including mechanistic insights and in vivo validation are needed to fully assess their therapeutic potential.

Keywords: *Pinus brutia*, OPC, HT-29, A549, Cytotoxicity, MTT assay, Selective activity

INTRODUCTION

Pinus brutia Ten. (Turkish red pine), widely distributed in the Eastern Mediterranean and Aegean regions, is an ecologically and economically valuable tree species. In recent years, its bark has gained significant scientific interest as a rich source of phenolic compounds, particularly oligomeric proanthocyanidins (OPCs)(Cretu et al., 2013). OPCs are well documented for their strong antioxidant, anti-inflammatory, and potential anticancer properties. Previous studies on *P. brutia* bark have mainly focused on antioxidant and antimicrobial activities, while limited research has addressed its cytotoxic potential on cancer cell lines (Secim-Karakaya et al., 2021; Dönmez & Önem, 2024). A few studies demonstrated moderate cytotoxic effects of crude extracts or fractions from *Pinus* species against various tumor cells; however, detailed investigations targeting colon and lung cancer models with selective toxicity against malignant cells remain scarce (Sharifan et al., 2021).

Given the increasing interest in natural, selective anticancer agents, the cytotoxic potential of OPCs derived from *P. brutia* bark represents an important research gap. In particular, the solvent system employed during extraction may critically influence the solubility, bioavailability, and biological activity of these compounds (Kaczorová, et al., 2021). Therefore, the present study aimed to evaluate the cytotoxic effects of OPC-rich ethanol (PBET) and ethanol:water (PBAS) extracts from *P. brutia* bark against human lung carcinoma (A549), colon adenocarcinoma (HT-29), and normal human colon fibroblast (CCD18-Co) cell lines. This study not only provides new insights into the anticancer potential of *P. brutia* bark OPCs but also contributes to the growing evidence supporting their role as selective, plant-derived therapeutic agents.

MATERIAL AND METHOD

Cytotoxic Activity

The cytotoxic effects of PBET and PBAS were evaluated against two human cancer cell lines A549 (lung cancer cell line) and HT-29 (kolon cancer cell line) as well as a non-tumorigenic normal human colon fibroblast cell line (CCD18-Co). Cytotoxicity was assessed using the MTT assay (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide), according to the method described by Plumb (2003) and Belhouala et al. (2024). Cells were seeded in 96-well plates at a density of 1,000 cells per well in triplicate and incubated for 24 hours under standard conditions (37 °C, 5% CO₂, and 95% relative humidity). The extracts were applied at different concentrations (0-200 µg/mL), and the cells were further incubated for 72 hours. Cells treated with cisplatin or doxorubicin were used as positive controls. After each incubation period, 10 µL of MTT reagent (5 mg/mL in phosphate-buffered saline; Applichem, USA) was added to each well. Following a 4-hour incubation, the medium was carefully removed, and 100 µL of pure DMSO was added to solubilize the purple formazan crystals formed by viable cells. The absorbance was measured at 540 nm using a microplate reader. The IC₅₀ values (± standard deviation) for each extract were calculated for the 72-hour treatment period to assess the cytotoxic potential against cancer cell lines and normal cell lines.

Statistical Analysis

For cytotoxic activity, statistical analysis was performed using GraphPad Prism version 8, including one-way ANOVA followed by Tukey's multiple comparison tests. A *p* value < 0.05 was considered statistically significant. The IC₅₀ values were determined from regression curves generated from the percentages of inhibition or absorbance at different concentrations, as previously described.

RESULTS AND DISCUSSION

The cytotoxic activity of PBET and PBAS extracts was assessed using the MTT assay after 72 hours of treatment across a concentration range of 0–200 $\mu\text{g/mL}$. As shown in Table 1, PBAS exhibited the most potent cytotoxicity against the HT-29 colon cancer cell line, with an IC_{50} value of $40.87 \pm 0.15 \mu\text{g/mL}$, nearly twice as active as PBET (IC_{50} : $95.10 \pm 0.07 \mu\text{g/mL}$). On the A549 lung cancer cell line, both extracts showed relatively weaker activity ($\text{IC}_{50} > 100 \mu\text{g/mL}$), indicating that colon cancer cells were more susceptible to OPC treatment. Importantly, neither PBET nor PBAS displayed significant cytotoxicity on healthy CCD18-Co fibroblast cells ($\text{IC}_{50} > 200 \mu\text{g/mL}$), highlighting the selective nature of these extracts toward malignant cells.

The enhanced cytotoxicity of PBAS compared to PBET may be attributed to the ethanol:water solvent system, which likely improved the solubility and extraction efficiency of OPCs, resulting in higher bioactive content. Selective cytotoxicity is a highly desirable property in anticancer drug discovery, as it minimizes damage to healthy cells. Compared with cisplatin, a standard chemotherapeutic drug that showed strong activity but also non-selective toxicity, OPC-rich extracts demonstrated a safer profile with potential therapeutic relevance.

These findings are consistent with previous reports highlighting the anticancer potential of proanthocyanidins from other plant species, which act through mechanisms such as induction of apoptosis, inhibition of cell proliferation, and modulation of oxidative stress (Wang et al., 2019; Albogami, 2020). However, further studies are necessary to elucidate the precise molecular pathways underlying the activity of *P. brutia* OPCs.

Table 1. Cytotoxic activities of extracts of various plants against lung and colon (A549 and HT-29) cancer cell lines and their cytotoxicity against healthy human (CCD18Co) cell line

Extracts/ Reference of plant codes	Cancer Cell Lines		Human Cell Line
	A549	HT-29	CCD18-Co
	$\text{IC}_{50}(\mu\text{g/mL})$	$\text{IC}_{50}(\mu\text{g/mL})$	$\text{IC}_{50}(\mu\text{g/mL})$
PBET	>100	$95.10 \pm 0.07^*$	>200
PBAS	>100	$40.87 \pm 0.15^*$	>200
Cisplatin	4.01 ± 0.05	4.05 ± 0.04	NT

Values are shown as mean $\pm$ SD (n = 3) (* significant at $p < 0.05$) (Table 1) (NT; not tested)

CONCLUSIONS

This study demonstrates, for the first time, the selective cytotoxic potential of OPC-rich extracts from *Pinus brutia* bark against human colon (HT-29) and lung (A549) cancer cell lines. The ethanol:water extract (PBAS) displayed the strongest cytotoxicity on HT-29 cells, while both PBAS and PBET were non-toxic toward normal fibroblast cells, underlining their selective activity. These results suggest that *P. brutia* bark OPCs could serve as promising candidates for the development of natural anticancer agents with reduced side effects compared to conventional chemotherapeutics.

The findings of this study are particularly important as they highlight the role of extraction solvent systems in modulating biological activity and provide a foundation for further research on compound isolation, structural characterization, and mechanistic studies. Moreover, the selective anticancer activity observed here may encourage *in vivo* investigations and inspire the development of OPC-enriched formulations or functional nutraceuticals for cancer prevention and therapy. Ultimately, this work contributes to filling a significant gap in the literature on *P. brutia* and positions its bark as a valuable bioresource for anticancer drug discovery.

EXPLORATORY FACTOR ANALYSIS OF FRUIT FARMERS' ECO-FRIENDLY AGRICULTURAL TECHNIQUES APPLICATIONS IN TERMS OF SUSTAINABLE AGRICULTURE-ENVIRONMENT RELATIONS: EVIDENCE FROM EĞİRDİR LAKE IN TURKEY

Feyza BITIRAK, Hasan YILMAZ

Isparta University of Applied Sciences, Faculty of Agriculture, Department of Agricultural Economics, Isparta, Turkey

ABSTRACT

The agricultural sector today faces multidimensional threats such as climate change, depletion of natural resources, environmental pollution, and biodiversity loss. This necessitates the widespread adoption of environmentally friendly practices, particularly in input-intensive agricultural systems such as fruit growing. The Lake Eğirdir basin, located in Türkiye's Western Mediterranean Region, serves as a notable example in this regard. Lake Eğirdir, Turkey's fourth largest freshwater source, is both a drinking water reservoir and the center of the region's agricultural activities, based on apple and cherry production. However, the increased use of pesticides and chemical fertilizers leads to deterioration of water quality in the lake ecosystem, posing a significant risk to environmental sustainability. This study examined the level of adoption of environmentally friendly agricultural techniques by fruit farmers around Lake Eğirdir using factor analysis. The Cronbach's alpha value for a 24-item scale, based on data obtained from 135 farmers, was found to be 0.733. As a result of the factor analysis, eight main factors were revealed that explain 64.72% of the total variance: Factor (1) Sustainable soil and pest management; Factor (2) Controlled Input Use; Factor (3) Sustainable and traceable agricultural practices; Factor (4) Conscious approach to input and product processes; Factor (5) Conscious weed control; Factor (6) Ecological sensitivity in agricultural practices; Factor (7) Environmental awareness and access to information; Factor (8) Conscious and controlled agricultural production. The results obtained reveal that sustainability and ecological awareness are also important determinants in farmers' agricultural activities. They also emphasize the necessity of disseminating an environmentally sensitive production approach for the protection of Lake Eğirdir.

Keywords: Sustainable agriculture, environmentally friendly practices, fruit growing, Lake Eğirdir

INTRODUCTION

Agricultural production faces multifaceted and increasingly pressing threats, including climate change, depletion of soil and water resources, loss of biodiversity, and environmental pollution. These environmental pressures question the sustainability of traditional production and necessitate the adoption of ecologically based approaches to agricultural production. A sustainable agriculture approach requires the implementation of environmentally friendly practices and calls for comprehensive policies and practices that include reducing chemical

inputs, protecting natural resources, and restructuring agro-ecosystems. (Altieri, 2018; Pretty, 2008; FAO, 2017).

Türkiye, which hosts ecological diversity and different climate zones, has a significant production potential in terms of fruit growing. (Uzun et al., 2009; FAO, 2009; Wikipedia, 2025). The Lakes Region in the Western Mediterranean, one of the regions where this potential is prominent, stands out nationwide, particularly in apple and cherry production. The Lake Eğirdir basin, one of the region's most important natural resources, is central to agricultural production for the region's population with its freshwater resources and favorable climate conditions. Fruit growing, in particular, stands out as a key source of income for the local economy.

Lake Eğirdir is under threat of losing its ecosystem function due to increasing environmental pressures in recent years. Climate change, unregulated water use, and intensive agricultural activities in particular have led to significant declines in the lake's water level and quality, threatening the ecosystem. (Ministry of Environment, Urbanization and Climate Change, 2021). Compounds such as nitrogen and phosphorus, especially those carried into the lake along with pesticides and chemical fertilizers, have led to deterioration in the lake's physicochemical parameters, which in turn threaten aquatic life by causing algal blooms and reduced dissolved oxygen. (Bulut, Atay & Uysal, 2009; Bulut et al., 2018). This lack of oxygen poses a vital threat to many aquatic organisms, especially fish; this situation reduces the biodiversity in the lake and endangers the sustainability of the ecosystem. (FAO, 2017).

These environmental pressures necessitate the expansion of new agricultural policies and production techniques based on sustainability principles. Farmers shift towards environmentally friendly techniques not only reduces pressure on ecosystems but also plays a critical role in ensuring food security, adapting to climate change, and supporting rural development. (UNEP, 2011; FAO, 2017).

This study examines the adoption of environmentally friendly agricultural techniques by fruit farmers operating around Lake Eğirdir and aims to analyze the behavioral and structural factors underlying these techniques using factor analysis. In addition to contributing to the reduction of environmental risks in natural resource use at the regional level, the study also aims to provide scientific evidence for sustainable agricultural-environmental policies that consider agriculture-environmental relationships.

MATERIALS AND METHODS

Data Collection

Primary data for this study were obtained through face-to-face surveys conducted with 135 farmers in agricultural holdings in and around the Eğirdir district of Isparta province, located in Turkey's Lakes Region. Lake Eğirdir and its surrounding area was chosen as the research area because Lake Eğirdir is a significant source of drinking and agricultural irrigation water; it holds a significant share of the region's intensive fruit production, particularly apple and cherry production (Boyras et al., 2005; Emre et al., 2011), which is a significant part of the country; it has a high level of agricultural mechanization (Pressurized irrigation system)

(Gökdoğan et al., 2011) and various studies have demonstrated farmers tendency to adapt to innovations (Öztürk et al., 2013).

During fieldwork, farmers agricultural production techniques, environmental awareness levels, and attitudes toward sustainable practices were analyzed in detail.

The sampling frame consisted of a total of 1,529 agricultural enterprises engaged in fruit cultivation around Lake Eğirdir. Farmer lists from these enterprises were obtained from the relevant district directorates and were used as the population. The sample size for the study was determined using a simple random sampling method. The sample size was calculated according to the formula below. (Çiçek et al., 1996).

The number of sample businesses was calculated using equation (1).

$$n = \frac{N * S^2 * t^2}{(N - 1) * d^2 + S^2 * t^2}$$

In the formula:

n: Required sample size,

N: Population size (1,529 farmers),

S²: Population variance (766.76),

d: Acceptable margin of error (10% of the mean),

t: t-value corresponding to a 90% confidence level (1.65)

In this study, the sample size that would statistically represent the target population was calculated using standard sampling formulas. Based on calculations based on a 90% confidence level and a ±10% margin of error, it was determined that 135 agricultural enterprises would be appropriate to include in the sample. This sample size, in light of basic statistical principles, allows for generalizable results to be obtained regarding the research population and supports the reliability of the study. (Newbold et al., 2013).

Data Analysis

Factor Analysis

To ensure the sustainable use and protection of Lake Eğirdir, one of Turkey's important freshwater resources, factor analysis was conducted to reveal the attitudes and approaches of farmers engaged in intensive fruit growing around the lake toward environmentally friendly agricultural techniques. In this context, farmers were presented with a scale consisting of 24 statements covering topics such as environmental awareness, nature conservation approaches, and sustainable agricultural preferences and practices. Agreeing with each statement was measured using a 5-point Likert-type scale (1 = Strongly disagree, 5 = Strongly agree).

Factor analysis was used during the data analysis process to uncover underlying patterns among variables and reduce the size of the data set. This method simplifies complex data structures by summarizing a large number of variables into a smaller number of meaningful constructs. (Costello et al., 2005; Williams et al., 2010). Factor analysis allows the interpretation of a large number of variables, especially those with high correlations, by grouping them under common factors. (Beavers et al., 2013; Watkins, 2018).

This analysis technique aims to uncover non-independent (latent) structures among variables. However, for factor analysis to yield reliable results, several fundamental assumptions must be met. The most important of these is the existence of significant

correlations between variables. If there is insufficient correlation between variables, factor analysis may not be an appropriate method. (Field, 2018; Tabachnick et al., 2013).

Before analysis, it is recommended to apply the KMO and Bartlett tests to determine whether the relationships between variables are suitable for factor analysis (Suhr, 2006). The KMO value measures whether there is a sufficient level of common variance among variables, and values above 0.80 are considered "excellent," between 0.70 and 0.79 are "good," between 0.60 and 0.69 are "moderate," between 0.50 and 0.59 are "poor," and values below 0.50 are "unacceptable" (Büyüköztürk, 2002; Hair et al., 2010). A significant Bartlett test of sphericity ($p < 0.05$) indicates that there is a sufficient level of relationship between the variables and that they are suitable for factor analysis (Tabachnick et al., 2013; Williams et al., 2010).

Principal Component Analysis (PCA) was applied to determine the factor structure. This method aims to maximize the total variance in the data set (Smith, 2002). The Kaiser criterion was used to determine the number of factors, and only factors with an eigenvalue >1 were included in the analysis. (Wikipedia, 2025).

The Varimax orthogonal rotation technique was used to facilitate easier and more meaningful interpretation of the resulting factor structure. This method ensures that each variable loads heavily on only one factor, allowing for easier and more meaningful interpretation of the factor structure. Factor loadings of 0.50 and above were considered significant, and cross-loading items were excluded from the analysis (Williams et al., 2010).

Additionally, Spearman rank correlation coefficients were calculated and consistency analyses were conducted to examine the relationships among variables within each factor. Internal consistency of the scale was assessed using Cronbach's alpha, and a value of $\alpha \geq 0.70$ generally indicates reliability (Nunnally, 1978; Tavakol et al., 2011). Within the scope of this approach, the Cronbach Alpha value of the developed scale was calculated as 0.77 and it was determined that the scale was reliable. (Türel et al., 2019).

All statistical analyses were performed using SPSS for Windows 16.0 package program. (SPSS Inc., 2008).

RESEARCH FINDINGS AND DISCUSSION

Table 1 presents 24 propositions developed to identify the factors that play a role in determining fruit farmers' environmentally friendly agricultural practices for the sustainable use and protection of Lake Eğirdir. Some of these propositions were derived from previous studies, while others were determined through interviews with District Directorate of Agriculture technical staff and experts in the field. These propositions cover the following topics: protecting soil and water resources, controlled chemical use, biological control, analysis-based fertilization, use of certified inputs, and environmentally friendly practices related to ecological production processes. These approaches reflect the environmentally sensitive, planned, and conscious production approach that forms the basis of sustainable agriculture.

Descriptive statistics for the 24 variables used in the study are presented in Table 2. The means obtained from the assessment of fruit farmers' perceptions of the application of environmentally friendly agricultural techniques in terms of sustainable agriculture-environment relationships are shown in descending order. Farmers' levels of agreement with recommendations regarding the application of environmentally friendly agricultural techniques varied ($X_{19} = 4.6370$; $X_5 = 1.800$). Accordingly, the environmental practice with the highest agreement among farmers was "paying attention to the time between the last pesticide application and harvest" (X_{19} , Mean = 4.64, SD = 0.94). This finding indicates that farmers are particularly aware of food safety and chemical residue issues. Similarly, high means were also obtained for practices such as controlled use of pesticides (X_3 , Mean = 4.44) and controlled use

of fertilizers (X4, Mean = 4.41). This indicates that farmers exhibit environmentally sensitive behaviors regarding plant protection and nutrition.

On the other hand, some environmental practices have low mean values. Particularly low means were observed for techniques such as controlled hormone use (X5, Mean = 1.80), prioritizing non-chemical (biological, cultural, etc.) control methods (X8, Mean = 2.10), and implementing crop rotation (X24, Mean = 2.44). These results suggest that some environmentally friendly agricultural practices are not being adopted sufficiently due to lack of knowledge, inadequate infrastructure, or cost. (Altieri, 2018; Dessart et al., 2019).

In addition, high averages in variables such as the use of organic fertilizer (X12, Average = 3.90), the use of environmentally friendly irrigation techniques (X11, Average = 4.30) and the effective use of communication tools to raise awareness (X15, Average = 4.24) indicate a positive trend towards sustainable agriculture.

Table 1. Farmers Practices of Environmentally Friendly Agricultural Production Techniques

Codes	Variables
X1	I apply techniques in soil tillage that protect the physical structure of the soil and reduce erosion.
X2	I carry out land reclamation practices while engaging in agricultural production.
X3	I use pesticides in a controlled manner during agricultural production.
X4	I use fertilizers in a controlled manner during agricultural production.
X5	I use growth hormones in a controlled manner during agricultural production.
X6	In agricultural production, I use registered and certified seeds, seedlings, and saplings.
X7	To ensure proper timing and dosage of fertilization, I have soil analyses done at least once a year and leaf analyses when needed.
X8	In combating plant diseases and pests, I first apply cultural measures, physical control, biological control, mechanical control, and biotechnical methods and only as a last resort do I turn to chemical control.
X9	In chemical control, I use selective, environmentally friendly pesticides with low residue risk.
X10	I keep records of all pesticide applications used in chemical control.
X11	In agricultural production, I use appropriate irrigation techniques that provide the water needed by the plant while preventing water waste.
X12	In my agricultural production, I use organic, green, farmyard manure, and compost.
X13	In animal production (if available), I avoid overgrazing on pastures.
X14	I take necessary measures to maintain soil fertility (crop rotation, fallow, forage crops, or legume planting, etc.).
X15	I effectively use communication tools to raise my awareness level in agricultural practices
X16	I ensure that harvesting, storage, processing, and packaging activities are carried out within ecological methods.
X17	I pay attention to preventing microbiological contamination at all stages of production.
X18	I use sprayers suitable for applying pesticides that do not cause environmental pollution.
X19	I pay attention to the interval between the last pesticide application and harvest.
X20	I avoid pesticide application during the flowering period of plants.
X21	I avoid pesticide application in ecologically sensitive areas of regional importance (such as drinking water basins).
X22	I do not apply pesticides against diseases and pests below the economic threshold.
X23	I apply herbicides consciously.
X24	I practice proper and economical crop rotation.

According to the descriptive statistics presented in Table 2, farmers' attitudes toward environmentally friendly agricultural techniques vary. The average scores for 11 of the 24 propositions are above 3.50, indicating a generally positive perception of these techniques by farmers. This group of propositions includes practices such as paying attention to the time between the last spraying and harvest (X19, Mean = 4.6370), controlled use of pesticides and fertilizers (X3, X4), choosing appropriate irrigation techniques (X11), effective use of communication tools (X15), organic fertilizer applications (X12), avoiding spraying during flowering (X20), selective use of pesticides (X9), land reclamation (X2), keeping pesticide records (X10), and pesticide sensitivity based on ecosystem sensitivity (X21). This suggests

that farmers have environmental awareness primarily focused on input management, timing, recording, and conscious chemical use.

In contrast, the remaining 13 statements, where the mean values remain below 3.50, indicate that farmers have either not sufficiently adopted some environmentally friendly practices or have low implementation levels. These negatively perceived statements include fertilization based on soil and leaf analysis (X7), conscious weed control (X23), avoiding overgrazing (X13), soil protection techniques (X1), avoiding economical subthreshold spraying (X22), microbiological contamination measures (X17), soil fertility preservation methods (X14), appropriate sprayer use (X18), certified input use (X6), ecological harvesting and packaging methods (X16), economical crop rotation (X24), integrated pest control (X8), and controlled hormone use (X5). These findings reveal a low level of awareness, particularly in areas such as field-level analysis-based planning, biological control techniques, and certified production.

These results suggest that farmers have a positive approach to some environmentally friendly practices, but are more hesitant, particularly in practices requiring technical knowledge and cost. This situation points to the areas where training programs should be targeted and provides guidance for more effective planning of environmentally sensitive agricultural policies. (Pretty, 2008).

Factor analysis results revealed an eight-factor structure explaining 64.72% of the total variance. Factor 1 explained 11.57% of the total variance and was named "Sustainable Soil and Pest Management." This factor 1 was explained by variables X1, X8, X14, X21, X22, and X24. In this context, it was determined that farmers:

- Implemented soil tillage techniques that would preserve the physical structure of the soil and reduce erosion (X1),
- Prioritized cultural, biological, mechanical, and biotechnical methods for controlling plant diseases and pests, resorting to chemical control as a last resort (X8),
- Implemented measures such as crop rotation, fallow, and forage or legume planting to maintain soil fertility (X14),
- Avoided spraying in sensitive ecosystems such as drinking water basins (X21),
- Did not spray against diseases and pests below the economic threshold (X22),
- And implemented appropriate and economical crop rotation (X24).

These findings demonstrate that farmers are developing an environmentally conscious approach to agricultural production. The literature indicates that nitrate and phosphate pollution resulting from pesticide and chemical fertilizer use poses serious ecological risks, particularly for surface and groundwater resources (Singh et al., 2021; OECD, 2012). This highlights the importance of farmers adopting environmentally conscious practices to reduce the environmental impact of agricultural activities. These practices significantly contribute to the protection of water and soil resources.

Factor 2, which explains 10.06% of the total variance, is defined as "Controlled Input Use." This factor is strongly correlated with variables X3 (controlled pesticide use) and X4 (controlled fertilizer use). The findings indicate that farmers are adopting controlled approaches to the use of agricultural inputs (especially pesticides and fertilizers). This is a crucial behavior for both environmental sustainability and economic efficiency. Careful and prudent use of input management contributes to the conservation of natural resources and can also reduce production costs. (Pretty, 2008).

Factor 3 explains 8.57% of the total variance and is labeled "Sustainable and Traceable Agricultural Practices." This factor is represented by variables X10 (keeping records of pesticide application), X11 (using appropriate irrigation techniques), and X12 (using organic, green manure, and compost). Findings indicate that farmers are increasing their awareness of environmentally friendly production processes and are adopting conscious practices accordingly. Providing the plants with the necessary water efficiently, adopting irrigation techniques that prevent water waste, and expanding the use of organic fertilizers instead of chemical fertilizers are critical to the development of sustainable production systems. Furthermore, keeping records of pesticide application operations is a valuable practice for both traceability and food safety. (Altieri, 2018).

Factor 4, "Conscious Approach to Input and Product Activities," explains 8.14% of the total variance. This factor is highly loaded with variables X5 (controlled hormone use), X18 (environmentally friendly sprayer use), and X16 (ecological harvesting, storage, processing, and packaging). The variables included in this factor demonstrate that inputs used in the production process should be evaluated not only by their content but also by their application methods and post-harvest processes. Controlled hormone applications, in particular, are critical for both plant development and product quality. Uncontrolled use of hormone residues poses serious threats to the environment and food safety. (Türkyılmaz et al., 2022).

Endocrine-disrupting chemicals (EDCs), in particular, are known to cause adverse consequences on animal and human health, such as reproductive disorders, hormonal imbalances, and neurodevelopmental effects (Damstra et al., 2002). This poses a threat to both human health and the sustainability of ecosystems. Similarly, directing pesticides to the target plant using appropriate nozzle (sprayer) technology and correct application techniques ensures that the pesticide reaches the correct location. This minimizes spread to non-target areas, reduces environmental impact, and reduces operator exposure to chemicals (Van de Zande et al., 2021).

Furthermore, carrying out harvesting, storage, processing, and packaging processes in accordance with ecological principles ensures sustainability not only in field production but throughout the entire chain from product delivery to consumer. This holistic approach should be considered an essential component of sustainable agricultural systems (UN ESCAP, 2016; Whitfield et al., 2023).

Therefore, this factor represents a production approach that includes not only the correct selection of inputs but also environmentally friendly, technically supported, and hygienic practices.

Factor 5, explaining 6.78% of the total variance, was labeled "Conscious Weed Control." This factor is highly correlated only with the X23 (I use weed control consciously) variable (factor loading = 0.817), representing a univariate but significant structure.

This prominent factor variable demonstrates that farmers adopt a conscious, selective, and targeted approach to weed control. Applying pesticides at the right time, at the right dose, and in the right place is crucial for reducing both economic and environmental impacts in controlling weeds. Unnecessary or broad-spectrum pesticide applications can harm non-target plants and organisms, disrupt soil microbial structure, and cause pesticide accumulation in water resources. (Drocco et al., 2025).

In this context, this factor reflects the applicability of environmentally sensitive agricultural pest control methods and farmers' awareness levels on this issue. In particular, conscious pest control based on economic thresholds, rather than indiscriminate and high-dose pesticide use, is a fundamental approach to ensuring environmental sustainability (Karaca et al., 2020). Furthermore, such practices demonstrate that farmers have a production approach that considers both environmental and human health.

Factor 6, explaining 6.59% of the total variance, was labeled "Ecological Sensitivity in Agricultural Practices." This factor loaded highly with variables X2 (I conduct land reclamation work during agricultural production) and X20 (I avoid pesticide application during the flowering period).

This structure demonstrates that farmers plan their agricultural practices not only with a yield focus but also with an ecological sensitivity framework. Land reclamation provides long-term sustainability benefits such as improving soil physical properties, increasing water retention capacity, and preventing erosion (Gökoğlu et al., 2021). In this respect, it is a protective strategy aimed at preventing the depletion of natural resources.

Another prominent factor within this factor, avoiding pesticide application during the flowering period, is critical for protecting pollinator populations, especially bees. The inappropriate timing and application of pesticides can harm beneficial organisms, disrupt pollination services, and reduce biodiversity. (Basu et al., 2024).

These findings demonstrate that sustainable agriculture must be supported not only by technical knowledge but also by the ability to make and implement decisions in harmony with nature. Therefore, this factor demonstrates that farmers make agricultural decisions based on sensitive, long-term environmental planning that prioritizes ecosystem services (Şahin et al., 2020).

Factor 7, which explains 6.53% of the total variance, is labeled "Environmental Awareness and Access to Information." This factor is highly correlated with variables X13 (avoiding overgrazing in pastures) and X15 (effective use of information and communication tools in agricultural practices).

This factor demonstrates farmers' sustainable use of natural resources and informed decision-making. Preventing overgrazing of pastures is particularly important for protecting biodiversity, maintaining soil structure, and preventing erosion (Milazzo et al., 2023). Overgrazing causes irreversible damage to pasture areas, which negatively affects both animal production and the environmental balance in the long term.

On the other hand, the effective use of information and communication tools facilitates farmers' access to environmentally friendly agricultural techniques and ensures that practices are implemented based on scientific knowledge. This demonstrates the development of a knowledge-based production culture, a fundamental component of agricultural sustainability (Demirtaş et al., 2022).

The findings obtained under Factor 7 reveal that farmers act not only for production purposes but also with an awareness of environmental and social responsibility. Sustaining animal production in harmony with nature is considered a fundamental necessity not only for animal welfare but also for the protection of soil, water, and vegetation (Şahin et al., 2020).

Factor 8, which explains 6.47% of the total variance, is labeled "Conscious and Controlled Agricultural Production." This factor is represented by variables X7 (I have soil and leaf analysis performed for appropriate fertilization) and X19 (I pay attention to the time between the last spraying and harvest).

This structure reveals that farmers plan their agricultural practices based not only on traditional knowledge but also on measurements and analysis results. Soil and leaf analyses ensure correct fertilization in agriculture, increasing productivity and reducing environmental damage (Kaya et al., 2021).

Furthermore, allowing sufficient time between the last spraying and harvest plays a critical role in protecting food safety by preventing pesticide residues from remaining on the crop. This practice also serves as a preventative measure to prevent residues that could harm human health from reaching the market (Çetin et al., 2020).

Therefore, this factor is closely related to scientifically based decision-making, precision in timing, and a producer's awareness of prioritizing product safety. For sustainable agriculture, both natural resource use and pesticide applications must be carefully planned (Demirtaş et al., 2019).

Overall, examining the eight factors together reveals that farmers evaluate environmentally friendly agricultural practices with a multidimensional approach. While awareness of some factors (e.g., controlled use of chemical inputs) is high, implementation levels are lower for others (e.g., crop rotation or alternative pest management methods). These findings highlight the importance of supporting farmers in the region with training, technical support, and financial incentives for sustainable agricultural practices.

These findings suggest that overall, farmers in the region have a moderate to high level of awareness of environmentally friendly agricultural techniques, but some techniques need to be expanded and supported. Providing training, technical support, and financial incentives, particularly for areas with low averages, could contribute to sustainability goals. (Pretty, 2008; Tekeli et al., 2022).

Table 4. Application of Environmentally Friendly Production Techniques - Spearman's Rho Correlation Matrix

[illegible]

important at the level (2-tailed

* 0.05 important at the level (2-tailed)

**** 0.01**

Spearman rho correlation analysis was applied to assess the relationship between the factors. The correlation coefficients presented in Table 4 reveal statistically significant relationships ($p < 0.01$) between all pairs of variables. However, considering the magnitudes of the correlation values obtained, these relationships appear to be weak in practice. This suggests that the factors possess independent structures but may represent different dimensions of environmental sensitivity.

CONCLUSION AND RECOMMENDATIONS

As part of this study, factor analysis conducted to determine the attitudes and practices of fruit farmers around Lake Eğirdir toward environmentally friendly agricultural production techniques yielded an eight-factor structure. These factors reflect a wide range of behaviors, from practices that cause agricultural pollution to controlled chemical use, from ecological harvesting methods to analysis-based decision-making.

Each factor revealed how farmers define and implement environmental sustainability across different dimensions. Factors such as "Practices Causing Agricultural Pollution" and "Practices Sensitive to Time and Analysis," in particular, demonstrate the multidimensional nature of environmental sustainability at both the structural and administrative levels.

Spearman rho correlation analysis, conducted to determine the relationships between factors, revealed statistically significant relationships ($p < 0.01$) between all factor pairs. However, the generally low correlation coefficients suggest that these relationships have a weak impact on implementation. This suggests that each factor influences farmers' sensitivity to environmentally friendly agriculture in different ways, indicating that there is no strong structural dependence between them.

Therefore, farmers' environmental sensitivity, rather than being a homogeneous attitude, exhibits a multidimensional, area-based structure that varies by behavior type. This result indicates the need to develop holistic and multi-level policy tools that address different dimensions rather than a single, discrete approach to disseminating environmentally sensitive agricultural practices. In this context, it is crucial to increase and strengthen farmer training activities on sustainable agricultural techniques in the study region. Agricultural environmental policies and legal regulations should be implemented with a proactive approach to ensure the sustainability of Lake Eğirdir, an ecologically and economically important natural resource, and to implement them for sustainable water use.

ABSTRACT

In this study, millet (*Panicum miliaceum* L.) was germinated for three days to improve bioactive components. Flour obtained from germinated millet was used at different ratios (0-20%) in the production of leavened and unleavened flatbread with replacing wheat flour. Control leavened and unleavened flatbreads were produced from wheat flour. Color, diameter, thickness, spread ratio, antioxidant activity (DPPH, FRAP and CUPRAC) and phenolic (free, bound and total) contents of all breads were determined. The use of high ratios of germinated millet flour (GMF) increased the diameter, and surface a* and b* color values of both. The bound, free and total phenolic content of leavened flatbread increased up to 2522.22 mg GAE/kg, 5250.83 mg GAE/kg and 7773.04 mg GAE/kg, respectively with 20% GMF usage. As the GMF ratio increased, antioxidant activity values (DPPH, FRAP and CUPRAC) of leavened and unleavened flatbreads were also increased. The highest phenolic contents and antioxidant activity values were achieved especially at the 20% GMF addition ratio.

Keywords: Germination, millet, leavened bread, unleavened bread, flatbread.

INTRODUCTION

Proso millet (*Panicum miliaceum* L.) is one of the oldest cereals. The caryopsis of millet is rich in carbohydrates, protein, mineral substances, and vitamins and its nutritive parameters are comparable or better than common cereals. Millet was richer in essential amino acids (leucine, isoleucine, methionine) than wheat. Functional components found in millet such as phenolic, antioxidant, beta-glucan and dietary fibers have positive effects on health and nutrition. On the other hand, some antinutritional factors such as phytic acid, oxalate, and tannins decrease the nutritional value of millet (Kalinova and Moudry, 2006; Kalinova, 2007). Germination is an economical and effective bioprocessing technique that increases digestibility and bioavailability of nutrients by reducing antinutritional factors. Germination results in the biosynthesis and accumulation of various secondary metabolites such as vitamin C, tocopherols, flavonoids, tocotrienols, γ -aminobutyric acid and phenolic compounds. Germinated grains have beneficial effects on health and free radical scavenging abilities (Koehler et al., 2007; Azeke et al., 2011; Kaur and Gill, 2020; Dhillon et al., 2020; Ceccaroni et al., 2020). There have been conducted many studies in the literature on the use of germinated cereals, legumes and pseudocereals in the preparation of cereal products (Torres et al., 2007; Tok, 2017; Zhu et al., 2017; Demir and Bilgiçli, 2020). In these studies, significant improvement in the nutritional and functional properties of end products has been determined with the use of germinated grains.

Bread is a cereal product that has an important place in meeting daily energy requirements. In recent years, interest in leavened and unleavened traditional flatbreads has increased. Various studies have been carried out to improve the nutritional and functional properties of these breads, which are commonly produced from refined wheat flour (Başman and Köksel, 1999, 2001; Coşkuner and Karababa, 2005; Levent et al., 2012; Levent and Bilgiçli, 2012a; Levent and Bilgiçli, 2012b; Madenci

et al., 2012; Yıldız and Bilgiçli, 2012). In this study, the effect of GMF on some technological and functional properties of leavened and unleavened flatbreads was investigated.

MATERIAL AND METHOD

Materials

Millet was purchased from Taşan Ticaret, Konya, Turkey. Wheat flour, salt, baker's yeast and sugar were procured from a local market in Konya.

Germination of millet

The millet germination process was performed according to Parameswaran and Sadasivam (1994) and Li et al., (2017) with some modifications. The surfaces of the samples were sterilized by soaking in a solution of 1.0% aqueous sodium hypochlorite for 15 minutes at room temperature and then rinsed with distilled water. Before germination, the grains were soaked overnight in distilled water (at room temperature) and germinated in the dark for 4 days at room temperature. The germinated grain was dried in an oven at 45 °C for 12 h and milled ($< 500 \mu\text{m}$) on a laboratory grinder with a 100% extraction ratio.

Leavened and unleavened breadmaking

Leavened flatbread samples were prepared according to the method given by Akbaş (2000). Wheat flour (200 g), salt (3 g), sugar (2 g), fresh yeast (5 g) and water were used to control leavened flatbread production. Unleavened flatbread was prepared according to Başman and Köksel (2001). To control unleavened flatbread production, wheat flour (200 g), salt (3 g) and water were used. In other leavened and unleavened flatbread formulations, wheat flour was replaced with GMF at 5, 10, 15 and 20% ratios.

Color measurement

The color measurements of flatbreads were performed using a chromometer Minolta CR-400 (Minolta Camera, Co., Ltd., Osaka, Japan). Parameters L^* , a^* and b^* determine a three-dimensional color space, in which L^* indicates lightness (100 = white; 0 = black), a^* values determine the redness (+) and greenness (−), and b^* values determine yellowness (+) and blueness (−). Hue angle ($\arctan(b^*/a^*)$) and SI value ($((a^{*2}+b^{*2})^{1/2})$) was calculated.

Technologic properties

The diameter and thickness of leavened flatbread and unleavened flatbread samples were determined according to Yıldız and Bilgiçli (2012). The spread ratio values of samples were found by dividing the diameter to the thickness value of flatbreads.

Antioxidant activity and phenolic content

The antioxidant activity of leavened flatbread and unleavened flatbread samples was determined using 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging assay (Gyamfi et al., 1999; Beta et al., 2005), ferric reducing antioxidant power assay (FRAP) (Yılmaz, 2019) and cupric ion reducing antioxidant activity assay (CUPRAC) (Apak et al., 2008). The free and bound phenolic content was determined based on the Folin-Ciocalteu colorimetric method as described by Naczk and Shahidi (2004). Total phenolic content was calculated as the sum of free and bound phenolic content. Phenolic content was expressed as gallic acid equivalents (mg of GAE/100 kg).

Statistical analysis

Leavened and unleavened flatbread results were analyzed separately. SPSS statistical program version 22.0 (SAS Institute Inc., Cary, NC, USA) was used for statistical data analysis. Mean values were compared with Duncan's multiple range test.

RESULTS AND DISCUSSION

Color values of leavened and unleavened flatbreads

Color values of leavened and unleavened flatbread containing different ratios of GMF are shown in Table 1. Increasing usage ratios of GMF decreased the L^* value of both bread types. For leavened flatbread, a^* value increased in all GMF usage ratios, but for unleavened flatbreads, 10% or more GMF usage increased a^* value. The reason for the decrease in lightness of the flatbread surface is probably

due to the Maillard reaction. Increasing amylase and protease enzyme activity with germination causes the Maillard reaction by increasing the amount of free sugar and amino acids (Goesaert et al., 2009).

Table 1. Color values of leavened and unleavened flatbread containing different ratios of GMF

Leavened flatbread					
GMF (%)	L*	a*	b*	SI	Hue

15	67.29±0.55d	-2.40±0.63b	24.78±1.37ab	95.51±1.11c	24.90±1.42ab
20	65.86±0.16e	-1.20±0.24a	26.41±1.17a	92.57±0.44d	26.46±1.16a

Means followed by the different letters within a column are significantly ($p < 0.05$) different. GMF: Germinated millet flour.

Marti et al. (2017) reported that the use of germinated wheat flour increased the crumb a^* , crust a^* and b^* values but decreased the bread crumb and crust L^* values. The use of GMF in both bread formulations increased the yellowness value and the highest values were reached with the use of 15-20% GMF. The high carotenoid pigment content of millet affected the b^* value of flatbreads. While the SI values of the bread decreased with the use of GMF, the Hue values increased.

Technologic properties of leavened and unleavened flatbreads

The diameter, thickness and spread ratio values of leavened and unleavened flatbread containing different ratios of GMF are given in Table 2. The diameter of the leavened flatbreads ranged from 17.32 to 18.28 cm and there was a slight increase in the diameter value with the use of GMF. The diameter value of bread using only 20% GMF was significantly ($p < 0.05$) higher than the control bread.

Table 2. Technologic properties of leavened and unleavened flatbread containing different ratios of GMF

Leavened flatbread			
GMF (%)	Diameter (cm)	Thickness (cm)	Spread ratio
0	17.32±0.16b	1.63±0.65a	10.63±0.05c
5	17.64±0.34ab	1.47±0.71ab	12.00±0.08bc
10	17.82±0.11ab	1.46±1.24ab	12.21±0.09bc
15	18.00±0.57ab	1.27±1.24bc	14.17±0.10ab
20	18.28±1.1a	1.18±1.33c	15.49±0.18a
Unleavened flatbread			
GMF (%)	Diameter (cm)	Thickness (cm)	Spread ratio
0	24.48±0.45c	0.16±0.17a	154.94±2.12e
5	26.34±0.48c	0.12±0.20b	227.07±1.52d
10	30.28±0.68b	0.10±0.03bc	296.86±0.11c
15	31.62±0.31b	0.08±0.03c	405.38±1.94b
20	34.92±2.15a	0.07±0.06c	471.89±0.39a

Means followed by the different letters within a column are significantly ($p < 0.05$) different. GMF: Germinated millet flour.

In unleavened flatbreads, the diameter value increased with the use of 10% or more GMF. The use of 15-20% GMF in leavened flatbreads decreased the thickness value; on the other hand, all usage ratios of GMF decreased the thickness of unleavened flatbreads compared to control. High GMF usage ratios increased the spread ratio in leavened flatbreads and all GMF usage ratios in unleavened breads. Diluting gluten content with GMF addition may cause a decrease in thickness. There are numerous studies in the literature about decreasing the volume or thickness of breads with the substitution of non-gluten flours or bran (Sidhu et al., 2001; Gómez et al., 2012; Levent and Bilgiçli 2012a; Levent and Bilgiçli 2012b).

Antioxidant activities of leavened and unleavened flatbreads

Antioxidant activities leavened and unleavened bread containing different ratios of GMF are presented in Table 5. DPPH, FRAP and CUPRAC antioxidant activity values for leavened bread ranged between 181.77-344.93 mg TE/kg, 0.54-1.39 $\mu\text{mol TE/g}$ and 3.61-8.34 $\mu\text{mol TE/g}$, and for unleavened bread changed between 152.89-300.91 mg TE/kg, 0.33-1.35 $\mu\text{mol TE/g}$ and 2.91-6.73 $\mu\text{mol TE/g}$, respectively. With the increasing use of GMF in leavened flatbreads, DPPH, FRAP and CUPRAC antioxidant activity values increased. In unleavened flatbreads, DPPH and CURAC values increased with increasing GMF ratio, while FRAP value increased with 10% or more GMF use. The highest antioxidant activity values were achieved with the use of 20% GMF in both bread types.

Table 5. Antioxidant activities leavened and unleavened flatbread containing different ratios of GMF

Leavened flatbread			
GMF (%)	DPHH (mg TE/kg)	FRAP ($\mu\text{mol TE/g}$)	CUPRAC ($\mu\text{mol TE/g}$)
0	181.77 $\pm$ 1.39e	0.54 $\pm$ 0.05e	3.61 $\pm$ 0.05e
5	204.21 $\pm$ 1.29d	0.67 $\pm$ 0.02d	4.10 $\pm$ 0.04d
10	232.13 $\pm$ 0.00c	0.88 $\pm$ 0.01c	5.20 $\pm$ 0.14c
15	292.33 $\pm$ 2.97b	1.02 $\pm$ 0.02b	6.56 $\pm$ 0.002b
20	344.93 $\pm$ 1.40a	1.39 $\pm$ 0.04a	8.34 $\pm$ 0.27a
Unleavened flatbread			
GMF (%)	DPHH (mg TE/kg)	FRAP ($\mu\text{mol TE/g}$)	CUPRAC ($\mu\text{mol TE/g}$)
0	152.89 $\pm$ 0.87e	0.33 $\pm$ 0.08d	2.91 $\pm$ 0.05e
5	187.20 $\pm$ 1.45d	0.42 $\pm$ 0.01d	3.74 $\pm$ 0.05d
10	224.87 $\pm$ 1.52c	0.84 $\pm$ 0.05c	4.15 $\pm$ 0.06c
15	240.18 $\pm$ 1.38b	0.96 $\pm$ 0.02b	5.03 $\pm$ 0.02b
20	300.91 $\pm$ 0.48a	1.35 $\pm$ 0.01a	6.73 $\pm$ 0.12a

Means followed by the different letters within a column are significantly ($p < 0.05$) different. DPPH: 2,2-diphenyl-1-picrylhydrazyl radical scavenging (TE: Trolox equivalent). FRAP: Ferric reducing antioxidant power CUPRAC: Cupric ion reducing antioxidant capacity.

Phenolic contents of leavened and unleavened flatbreads

Phenolic contents of leavened and unleavened bread containing different ratios of GMF are given in Table 4. Bound, free and total phenolic content of leavened flatbread increased up to 2522.22 mg GAE/kg, 5250.83 mg GAE/kg and 7773.04 mg GAE/kg with GMF usage. All addition levels of GMF increased the bound, free and total phenolic content of leavened flatbread. Bound, free and total phenolic content of unleavened flatbreads increased with the use of GMF as in leavened flatbreads, and the highest values were reached with the use of 20% GMF.

There are many studies reporting an increase in antioxidant activity and phenolic content in cereals and legumes with germination (Demir and Bilgiçli, 2021; Alvarez-Jubete et al., 2010; Žilić et al., 2014; Swieca and Dziki, 2015; Cankurtaran-Kömürcü, 2021). Sharma et al. (2015) determined that the total phenolic content (free/bound) increased significantly with the germination of foxtail millet. Cankurtaran-Kömürcü, (2021) used germinated modern and primitive wheat in different ratios to produce bread (0, 5, 10, 15 and 20%) and noodles (0, 15, 30, 45 and 60%). It has been reported that germinated wheat significantly increased the antioxidant activity and phenolic content of bread and

noodles. Demir and Bilgiçli (2021) used germinated quinoa flour at the rates of 0, 10, 20 and 30% in gluten-free pasta production and found that the antioxidant activity and phenolic content increased with increasing germinated quinoa flour.

Table 5. Phenolic contents of leavened and unleavened flatbread containing different ratios of GMF

CONCLUSIONS

In this study, the effects of GMF on the technological properties and bioactive components of leavened and unleavened flatbreads were examined. The findings were evaluated separately for leavened and unleavened flat breads. While the increase in the use of GMF decreased the L^* and SI values of the bread, it increased the a^* , b^* and Hue values. While higher a^* and b^* color values were determined in unleavened bread samples compared to leavened breads, lower L^* values were generally measured. Especially high utilization ratios of GMF increased the spread ratio values of the both breads. As predicted, unleavened flatbreads were determined as breads with higher diameter and spread ratio than leavened flatbreads. The use of GMF in flatbread production significantly ($p < 0.05$) increased DPPH, FRAP and CUPRAC antioxidant activity values. The highest antioxidant activity values were obtained with the use of 20% GMF. In addition, it was determined that the amount of free, bound and total phenolic content increased in both bread types with the use of GMF, and these values reached the highest amounts at the highest use of GMF. Utilization of 20% GMF resulted in the greatest redness, yellowness, diameter, spread ratio value and bioactive components of the breads.

ABSTRACT

The composting of cattle manure is a crucial process for transforming this organic waste into a soil amendment that is rich in nutrients. This practice plays an instrumental role in reducing the amount of waste sent to landfills and in mitigating greenhouse gas emissions. This environmentally friendly method sustainably enriches soils, which improves crop quality and plant health. There are two main types of composting: biological and chemical. While beneficial, biological composting is slow and requires rigorous management of environmental conditions to optimize decomposition by microorganisms. In contrast, chemical composting is faster and more economical, where chemical additives are used to accelerate decomposition. In this study we investigated a chemical method using nitric acid to oxidize cattle manure. The excess acid was neutralized with potassium hydroxide, leaving harmless residues such as potassium and nitrates, which are also powerful fertilizers. Scanning electron microscopy and energy dispersive X-ray spectroscopy (SEM-EDX) analyses showed that the concentration of nitric acid had a significant effect on compost quality. The results show a decrease in carbon concentration and an increase in nitrogen and potassium concentrations with higher nitric acid concentrations used in the composting process, illustrating the oxidation of organic matter and the incorporation of nitrogen and potassium into the compost. The C/N ratio, which is crucial for decomposition and plant nutrition, is optimal within a range of nitric acid concentrations from 0.05 N to 1.00 N, facilitating the production of high-quality compost. The texture of the samples analyzed by SEM also varies with nitric acid concentration, with higher and more uniform degradation of organic matter and a finer texture with improved porosity.

Keywords: Cattle Manure Composting, Chemical Composting, SEM-EDX, Soil Amendments, Fertilizer Production.

INTRODUCTION

Cattle manure composting is a vital process for efficiently converting it into a highly beneficial, nutrient-rich soil amendment (Larney et al., 2006). By reducing the amount of manure sent to landfills and greenhouse gas emissions, this practice promotes the recycling of organic materials and contributes to environmental preservation. The compost produced can be used to enrich soils in an ecological and economical manner, thereby improving crop quality and plant health.

Cattle manure composting can be achieved either biologically or chemically. Biological composting relies on the action of natural microorganisms, such as bacteria and fungi, which decompose the manure in the presence of oxygen. This aerobic process produces nutrient-rich compost that benefits soil structure and fertility. However, biological composting has some drawbacks. It is much slower than chemical composting, requiring careful management of temperature, humidity, and aeration conditions to optimize the process. Additionally, due to handling and exposure to organic materials, there is a potential risk of pathogen spread, including viruses such as COVID-19, though this risk can be mitigated by proper composting practices and health safety measures (Zeqiri & Biçoku, 2021).

In contrast, chemical oxidation uses chemical additives to accelerate manure decomposition (Jensen et al., 2013). In this case, care must be taken to ensure that the chemicals used are not hazardous and that chemical residues in the compost do not affect its quality and environmental impact. Chemical composting is significantly more economical than biological composting.

In our study, aiming to replace the traditional composting process, we conducted the chemical oxidation of cattle manure using nitric acid. The excess nitric acid at the end of the process is neutralized using potassium hydroxide. The remaining residues of this process are potassium and nitrates, which are not only harmless but also constitute potent fertilizers, thereby enriching our compost.

MATERIALS AND METHODS

Scanning electron microscopy and elemental analyses

Scanning electron microscopy (SEM) images and elemental analyses were performed using a Thermo Fisher Scientific Helios G4 UC system, equipped with Energy Dispersive X-ray Spectroscopy (EDX). The EDX analysis was conducted at an accelerating voltage of 20 kV and a beam current of 1.6 nA, with a spectrum acquisition time of 60 seconds.

Compost Preparation

A fixed amount of collected manure is weighed before and after drying to determine the moisture content. Once this step is completed, the manure is ground using a ball mill to obtain a homogeneous texture. Particles smaller than 250 micrometers are recovered by sieving and then stored dry in bags for later use. Three grams of this dried and ground manure are mixed with 15 ml of nitric acid (at concentrations of 1 M, 0.5 M, 0.1 M, 0.05 M, and 14 M), until a paste is formed. Finally, the paste's pH is adjusted using a potassium hydroxide solution to achieve a neutral pH. The resulting product is dried for characterization.

RESULTS

The pH of the compost obtained for samples treated with nitric acid showed an acidic pH, ranging from 3 to 5 depending on the acid concentration used before neutralization with KOH. After neutralization, the pH was adjusted between 6.5 and 7.5. The texture of the obtained samples appears to depend on the concentration of nitric acid used during their preparation. Higher concentrations of nitric acid result in more uniform degradation of organic matter, leading to a finer texture with improved porosity.

The texture of the prepared samples is shown in Figure 1. Image (a) presents raw cattle manure at a magnification of x4000. Images (b), (c), (d), and (e), also at x4000 magnification, show cattle manure samples treated with nitric acid at concentrations of 0.05 M, 0.5 M, 1 M, and 14 M, respectively.

Figure 1 SEM Images of (a) Raw cattle manure, (b) Cattle manure treated with $[\text{HNO}_3] = 0.05 \text{ M}$, (d) Cattle manure treated with $[\text{HNO}_3] = 1 \text{ M}$ and (e) Cattle manure treated with $[\text{HNO}_3] = 14 \text{ M}$

SEM-EDX is often used for the characterization analysis of composts (Manohara et al., 2017, Diquattro et al., 2018, Khare et al., 2023). The images show the presence of two types of structures in each sample. The first consists of particles of varying sizes and shapes, which may be dispersed or clustered. The images also demonstrate the formation of particle aggregates, which are sets of interconnected particles, indicating the presence of organic matter.

The quality of the obtained product was characterized by scanning electron microscopy coupled with energy-dispersive X-ray spectroscopy (SEM-EDX). This technique was used to study the shape and structure of the compost samples as well as their chemical composition. The effect of nitric acid concentration on the quality of the obtained compost was the first parameter we studied. For this purpose, we used the following concentrations: 0.05 M, 0.5 M, 1 M, and 14 M.

EDX analysis allowed us to identify the elements present in the compost, and the results are presented in Table 1. We focused particularly on the following elements: C, N, O, Al, Si, P, K, and Ca, which compose the compost. Special attention was given to C and N as they are key indicators of compost quality.

Table 1: EDX Analysis Results of raw cattle manure, cattle manure treated with $[\text{HNO}_3] = 0.05 \text{ M}$, cattle manure treated with $[\text{HNO}_3] = 0.5 \text{ M}$, cattle manure treated with $[\text{HNO}_3] = 1 \text{ M}$ and, cattle manure treated with $[\text{HNO}_3] = 14 \text{ M}$

Table 1: EDX analysis results of raw cattle manure and cattle manure treated with $[\text{HNO}_3]$ at concentrations of 0.05 M, 0.5 M, 1 M, and 14 M.

Element (%)	Raw cattle manure	$[\text{HNO}_3] = 0.05 \text{ M}$	$[\text{HNO}_3] = 0.5 \text{ M}$	$[\text{HNO}_3] = 1 \text{ M}$	$[\text{HNO}_3] = 14 \text{ M}$
C	40.21	43.87	36.68	38.30	8.51
N	0.08	4.97	6.47	5.63	10.07
O	42.67	41.89	39.92	45.94	39.16
Al	2.28	1.09	1.60	1.32	1.24
Si	5.42	1.05	1.65	0.96	0.18
P	0.77	1.37	2.24	0.78	0.12
K	1.01	1.22	7.62	2.04	39.67
Ca	7.57	3.67	2.31	3.04	0.39
C/N	502,63	8,83	5,67	6,80	0,85

The results show a decrease in carbon concentration with increasing nitric acid concentration during treatment, a consequence of the oxidation of organic matter. Nitrogen concentration in the compost increases in parallel with the nitric acid concentration used, which is expected as nitrogen comes from the acid. Additionally, potassium concentration in the compost increases with higher nitric acid concentrations because more potassium hydroxide is needed to neutralize the compost when the acid concentration is high. These observations highlight the significant impact of nitric acid concentration on the final chemical composition of the compost.

The C/N ratio decreases with the increase in nitric acid concentration used during oxidation. It remains favorable within a broad range of nitric acid concentrations from 0.05 N to 1.00 N.

Maintaining an optimal C/N ratio is essential for supporting decomposition and providing the necessary nutrients to plants after compost application (Azim et al., 2018). Achieving an optimal result over a wide range of nitric acid concentrations reduces manufacturing constraints.

CONCLUSION

This study highlights the effectiveness of chemical oxidation with nitric acid for cattle manure composting, demonstrating its potential to produce high-quality compost quickly and economically. Using nitric acid to oxidize manure, followed by neutralization with potassium hydroxide, not only accelerates the decomposition of organic matter but also enriches the compost with essential nutrients such as nitrogen and potassium. SEM and EDX analyses revealed that nitric acid concentration plays a crucial role in the final compost quality, influencing both its chemical composition and texture. In particular, the C/N ratio, a key indicator of compost quality, was found to be optimal within a range of nitric acid concentrations from 0.05 N to 1.00 N. This flexibility in nitric acid concentrations facilitates the production of high-quality compost without requiring extremely precise control of composting conditions. Chemical oxidation with nitric acid represents a promising method for valorizing cattle manure, providing a practical and eco-friendly solution for agricultural waste management and soil improvement.

mariol.meco@yahoo.com

ABSTRACT

Wulfenia baldaccii is an Albanian endemic and a Tertiary relict species, currently listed as Vulnerable (VU) on the Albanian Red List (2013). Its distribution is limited to a few sites in the western Albanian Alps, mainly on north-facing limestone grasslands at 900–2200 m a.s.l. We report a newly discovered population at Syri i Kaltër, Theth (600 m a.s.l.), representing the lowest known occurrence of the species. The plants were found on humid limestone walls, predominantly covered by mosses and frequently associated with *Ramonda serbica*, *Pinguicula hirtiflora*, *Parnassia palustris* and the liverwort *Marchantia polymorpha*. Its presence in permanently humid microhabitats of a major karstic spring highlights the site's exceptional ecological value, particularly for conserving Tertiary relict flora that are highly vulnerable to climate change and drought. Yet Syri i Kaltër is a popular tourist site, where increasing human activity threatens this vulnerable species. This finding underscores the need for targeted conservation measures and careful management of natural monuments hosting rare plants.

Keywords: *Wulfenia baldaccii*; Tertiary relict flora; Albanian Alps; karstic spring; conservation.

INTRODUCTION

The genus *Wulfenia* (Plantaginaceae) exhibits a remarkable disjunct distribution, occurring in the southeastern Alps (Carnic Alps), the southeastern Dinaric Alps, and the Amanos Mountains of southern Turkey. It is widely regarded as a Tertiary relict in southeastern Europe, with origins dating back to at least the Miocene. Except for the nominate variety of *W. orientalis*, all *Wulfenia* species are confined to montane or subalpine habitats. Growth in the genus is nearly continuous, interrupted only briefly by winter frost. All species require high light levels and depend on moist soils and humid air (Surina et al., 2014).

In Albania, two species occur: *W. carinthiaca*, native to the southeastern Alps and extending into northeastern Albania and northwestern North Macedonia, and *W. baldaccii*, a narrow endemic restricted to the Albanian Alps (Degen, 1897). According to Barina et al. (2017), *W. baldaccii* is restricted to the western Albanian Alps, where it occurs in a few localities on limestone substrates, usually in north-facing mountain grasslands at 1400–2200 m a.s.l. Herbarium records from the National Herbarium of Albania document the species at 14 sites (Tab. 1), mostly in the Shkodër and Malësi e Madhe districts, at 900–2100 m a.s.l. An early report by Lemperg from Ura e Djallit (Kukës) has not been confirmed in later surveys.

Tertiary relict species such as *W. baldaccii* are among the most vulnerable plant groups under climate change, particularly in Mediterranean and montane ecosystems where increasing aridity and warming are projected. Due to their narrow ecological tolerance, these species are highly sensitive to changes in temperature and moisture. Documenting the distribution and ecological conditions of *W. baldaccii* populations is therefore essential to provide baseline data for effective management and conservation strategies.

METHODOLOGY

Fieldwork at Syri i Kaltër was carried out within the project *Achieving Biodiversity Conservation through Effective Management and Enhanced Resilience to Climate Change in the Existing Protected Area of the North Albanian Mountainous Region*, implemented by the Urban Research Institute (URI) and funded by UNEP.

New localities of *Wulfenia baldaccii* were georeferenced with a Garmin Dakota 10 GPS. Ecological parameters were recorded, including substrate type, slope exposure, associated plant species, and population size. Both actual and potential threats to the species were also assessed.

Taxonomic identification followed Illustrated Flora of Albania (Pils, 2016) and Flora europaea (Tutin et al., 1964–1980). Distribution data were compiled from the Atlas of Vascular Plants of Albania (Barina et al., 2017) and from the register of the National Herbarium of Albania at the Research Center for Flora and Fauna, University of Tirana.

RESULTS AND DISCUSSIONS

We report a new locality of *W. baldaccii* at Syri i Kaltër, Theth (Albanian Alps; Fig. 1) at ~600 m a.s.l., the lowest altitude recorded for the species. Although this site lies relatively near previously known populations, the species' overall distribution remains highly restricted. Ecological conditions at this site may be especially favorable: the permanently humid environment supplies the soil and atmospheric moisture required by *W. baldaccii* as other Tertiary relicts.

Figure 1. Distribution of *Wulfenia baldaccii* in Albania (after Barina et al., 2017). The red dot marks the newly recorded locality at Syri i Kaltër, Theth.

The surveyed population occurs on shaded, humid limestone walls (Fig. 2), predominantly covered by the moss *Brachythecium* sp. Associated species include the relict *Ramonda serbica* and hygrophilous taxa such as *Pinguicula hirtiflora*, *Parnassia palustris*, *Cystopteris fragilis*, *Marchantia polymorpha*, and the orchid *Dactylorhiza saccifera*. Valley slopes support broad-leaved forests dominated by *Ostrya carpinifolia*, *Carpinus orientalis*, *Acer pseudoplatanus*, and *Acer obtusatum*, whereas upper slopes are characterized by beech (*Fagus sylvatica*) forests. The population size is estimated at 50–70 mature individuals.

Phytosociologically, the assemblage belongs to the alliance **Ramondion serbicae** (Blečić & Lakšić, 1970), comprising paleoendemic, hygrophilous chasmophytic communities on shaded calcareous cliffs of the Balkan Peninsula. The habitat's ecological specificity and the presence of glacial relicts underscore its conservation value.

The occurrence of *W. baldaccii* in permanently humid microhabitats of a major karstic spring highlights the site's exceptional ecological value, particularly for conserving Tertiary relict flora that depend on consistently high humidity and are highly vulnerable to climate change and increasing drought.

However, Syri i Kaltër is a popular tourist destination, and increasing human activity poses significant threats to this vulnerable species. The creation of informal paths, use of rock slopes as diving platforms, and similar disturbances may directly impact this rare endemic species. Furthermore, promoting the species as a tourist attraction could present an additional risk, as visitors may be tempted to collect flowers or even attempt to transplant individuals into private gardens. These findings underscore the urgent need for targeted conservation measures and careful management of natural monuments that harbor rare plant populations.

Figure 2. (1) Syri i Kaltër; (2) humid limestone walls with hygrophilous vegetation; (3) *W. baldaccii* with plant species and mosses; (4) *W. baldaccii* in fructification. *Photos by. M. Meço, Jul. 2025*

CONCLUSIONS

The discovery of *W. baldaccii* at Syri i Kaltër, Theth, extends the known distribution of this Albanian endemic to its lowest recorded altitude and identifies a particularly favorable habitat, characterized by the high moisture levels essential for the species' survival. The coexistence of *W. baldaccii* with other Tertiary relict such as *Ramonda serbica* and other hygrophilous taxa emphasizes the exceptional ecological and phytogeographical significance of this site. Despite its favorable ecological conditions, the population remains very small and highly vulnerable to anthropogenic pressures, particularly tourism-related disturbance. These findings underscore the urgent need for targeted conservation actions, including habitat protection, monitoring, and visitor management, to ensure the long-term survival of *W. baldaccii* and the unique relict flora of the Albanian Alps.

ABSTRACT

Air pollution has long been a significant factor affecting both human and environmental health. With increasing human population and industrialization, various pollutants have been released into the atmosphere. Among these, particulate matter is one of the most critical pollutants and poses a serious threat to living organisms. In particular, it contributes to various health problems, such as respiratory and cardiovascular diseases. Long-term exposure can lead to workforce loss and, in severe cases, even death. Each year, deaths related to air pollution also have a negative impact on national economies. To address these challenges and minimize potential harm, researchers have developed various approaches and models. One such tool is the Benefits Mapping and Analysis Program – Community Edition (BenMAP-CE), developed by the U.S. Environmental Protection Agency (EPA). BenMAP-CE enables health and economic risk assessments based on regional data. It utilizes air quality data, along with mortality, hospital admission, and economic metrics, to estimate improvements in quality of life and potential economic benefits resulting from better air quality. In this study, air quality monitoring data and WRF-Chem model simulations of particulate matter concentrations were used for the Kocaeli region. While the Kocaeli region is one of Türkiye's most industrialized and densely populated areas, it is also exposed to severe air pollution. Therefore, poor air quality can lead to serious health problems and even death. Cause-specific mortality data related to cardiovascular, respiratory, and other diseases were incorporated, and the BenMAP-CE model was applied to assess potential improvements in quality of life and associated economic gains under a scenario of a 50% reduction in particulate matter concentrations. The results estimate that more than one hundred deaths from cardiovascular and respiratory causes could be prevented, and the economic benefits could exceed one billion dollars. As a result of the Kocaeli districts, Izmit, Gebze and Darica within the Kocaeli province demonstrated the highest potential for benefit, whereas Dilovasi yielded relatively lower benefit, a more limited impact compared to the other districts.

Keywords: Air pollution, PM₁₀, BENMAP-CE, Health benefit, Economic benefit, Kocaeli, Türkiye.

INTRODUCTION

Air pollution remains one of the most important problems of the 21st century (Bridgman, 1991; Fang et al., 2013; Likhvar et al., 2015). As urbanization, industrialization, and population increase accelerate worldwide, the degradation of air quality has become an unavoidable serious health and environmental problem, especially in heavily populated and industrial areas. The World Health Organization (WHO) recognizes air pollution as a major public health risk, contributing significantly to the global burden of disease (McDuffie et al., 2021). Air pollution is caused by different pollutants, especially particulate matter (PM) is the most well-known pollutant due to its environmental and health impacts (Mukherjee and Agrawal, 2017; Zhao et al., 2013). Exposure to these airborne particles is

strongly linked to respiratory and cardiovascular diseases, premature mortality, and other health issues (Brook, 2008; Hoek et al., 2013; Lee et al., 2014; Shahriyari et al., 2022). Short-term exposure to particulate matter can cause acute health effects, including asthma attacks and hospital admissions for respiratory and cardiovascular complications, while long-term exposure may lead to premature death (Franchini and Mannucci, 2009). In addition, air pollution has substantial economic effects on countries. These include direct costs such as increased healthcare fees, as well as indirect costs related to productivity losses, reduced labor output, and premature deaths (Pandey et al., 2021). According to the Organisation for Economic Cooperation and Development (OECD), the global economic cost of air pollution caused by premature mortality alone might reach trillions of dollars per year if adequate control measures are not implemented (Lanzi, 2016). To analyze the health and economic impacts of air pollution, researchers and agencies have developed several methodologies and models. One of the most popular models is the Benefits Mapping and Analysis Program - Community Edition (BenMAP-CE). This model is designed to estimate the health benefits and related economic gains of air quality improvements, using data such as pollutant concentrations, population demographics, health incidence rates, and economic valuation metrics. BenMAP-CE gives comparative risk assessment by predicting avoided cases of disease and mortality under various pollution management scenarios.

The causes of air pollution can be examined as anthropogenic emissions and natural. The local air pollution is mainly affected by industrial areas, traffic, mining and residential heating. Kocaeli well know intense industrialization and high population density area. Studies conducted on health issues and air pollution have shown that pollutant concentrations in Kocaeli consistently exceed both national and international standards (Hamzaoglu et al., 2011; Unal, 2021). Therefore, Kocaeli region is important for the health risk. In the literature review of Kocaeli health risk from air pollution, Palanbek Yavaş et al. (2021) found that high levels of PM₁₀ and NO₂ in the Marmara and Kocaeli region, were linked to an increased risk of chronic bronchitis and mortality, highlighting air pollution as a serious public health issue. Öztürk et al. (2021) found that PM_{2.5} concentrations in Kocaeli's Izmit district reached significantly high levels in winter and often exceeding WHO and EPA limits, especially in traffic and urban areas, indicating a need for winter seasonal air quality controls and fossil fuel reduction to control health risks. Pekey et al. (2010) emphasize that indoor and outdoor PM_{2.5} and PM₁₀ concentrations measured in 15 homes across Kocaeli were significantly higher in winter, with outdoor PM₁₀ averaging 102.3 µg/m³, and that industrial emissions, vehicular traffic, and fossil fuel combustion were identified as major sources of pollution, while long-term exposure to these pollutants is believed to increase health risks. In this study, health and economic benefits of a 50% reduction in PM concentrations across the Koceli region were specifically investigated and analyzed.

MATERIAL AND METHOD

Kocaeli is one of the most crowded cities in Türkiye, hosting approximately 2.1 million residents as of 2023, and Izmit, the capital district of Kocaeli, covers an area of about 480 km² and is home to around 378,000 inhabitants (TURKSTAT, 2023a). The province is geographically connected to both the Marmara and Black Sea regions. Kocaeli consists of 12 districts: Izmit, Derince, Gebze, Golcuk, Kandira, Karamursel, Korfez, Basiskele, Cayirova, Darica, Dilovasi, and Kartepe. The city is mostly known for its industrial activities, including automotive, petrochemical, machinery, mining, metal, food, paper, cement, and tire production sectors (Sarper Erdogan et al., 2005). These industries have a significant effect on air pollution, releasing various pollutants into the atmosphere. Kocaeli is also a major transportation hub, intersected by key highways such as the D-100 and the Trans-European Motorway (TEM), which connect industrial areas with residential zones. Due to the traffic, industrial, and residential emissions, Kocaeli serves as a critical region for assessing the impacts of air pollution. All these factors negatively affected the air quality in the Kocaeli region, thereby posing a significant risk to public health (Hamzaoglu et al., 2011; Unal, 2021). The locations on the map of Kocaeli districts are given in Figure 1.

Figure 3. Study area and Kocaeli district locations

In this study, we used air quality monitoring station (AQMS) and WRF-Chem model data for the year 2023. This year was selected as the reference period because the most recent mortality dataset was available for this year. AQMS measurements were the main source of air quality data for the BenMAP-CE model. However, the model data is only used to identify missing values and to fill in missing stations in three districts: Yenikoy, Cayirova, and Kartepe. There are nine AQMS in the Kocaeli region, and each station measures different pollutants. PM₁₀ data were obtained from all of these nine stations. In the lack of AQMS in Kocaeli districts, the closest station data were used, and missing values were predicted with Weather Research and Forecasting model coupled with Chemistry (WRF-Chem) simulations (Figure 2). WRF-Chem is a mesoscale model developed to simulate the distribution of air pollutants and is particularly known for its capability to predict atmospheric chemical reactions (Peckham et al., 2018; Sicard et al., 2021). Air pollution is known to cause various adverse effects on human health, particularly in relation to respiratory and cardiovascular diseases. Therefore, in order to predict health risk assessments, both mortality and hospital admissions data can be used with air quality data. In this case study, health impacts were estimated based on mortality data, which were obtained for each district within the Kocaeli region. Additionally, Kocaeli University Research and Application Hospital data were used to improve health incidence estimates for cardiovascular and respiratory diseases. In Türkiye, mortality data were obtained from the Turkish Statistical Institute (TURKSTAT), while hospital admission data were only provided by Kocaeli University Hospital (TURKSTAT, 2023b). Therefore, hospital administration data were used only to support the mortality data. The last dataset, includes the economic valuation of the country, specifically for Türkiye. The economic calculation method followed the user guide example from Santiago, as provided in the BenMAP-CE training materials. Various economic data sources are available globally, such as calculation methods, data sets and standards. Therefore, in this study, the World Bank's World Development Indicators were primarily used, and the necessary data were supported by the The Organisation for Economic Co-operation and Development (OECD) and The International Monetary Fund (IMF) (IMF, 2025; OECD, 2023; World Bank, 2025).

Figure 4. The domain and namelist used in WRF-Chem model

BenMAP-CE is an open-source software tool developed by the United States Environmental Protection Agency (US EPA). The model was developed to estimate the health and economic impacts under scenarios of improving air quality or reducing air pollution. In this study, BenMAP-CE version 1.5.8 was selected as the health impact assessment tool. This version has been modified to enable the use of various pollutants and health impact functions across different scenarios to calculate health risks (Coffman et al., 2024). The model needs mortality data, population statistics, economic indicators, air quality data, hospital admissions in order to perform its calculations (US EPA, 2023). The BenMAP-CE model flow diagram can be shown in Figure 3.

The input datasets used in the model are listed below to provide a clearer understanding of the methodology. The model uses different parameters and methods that are designed for socio-economic calculations. As the calculation algorithm of BenMAP-CE, the model utilizes a specific health impact function, which is illustrated in Figure 4. In this study, the BenMAP-CE model was prepared by adapting the Santiago scenario provided in the official user guide training materials. Reference values required for the formulas, such as relative risk, odds ratio, and hazard ratio, were obtained from the example data in the training materials. We used cardiovascular, respiratory, and all-cause mortality data specific to the Kocaeli region for this case scenario. Additionally, prevalence data for cardiovascular and respiratory cases were collected from Kocaeli University Research Hospital. After that, air pollution reducing scenario needs to be chose for model. The final dataset required for the model is the economic data. Therefore, BenMAP-CE allows users to estimate the health and economic impacts based on the reduction in air pollution.

Figure 5. Inputs and outputs of BenMAP-CE model analysis

Figure 6. Health impact functions of BenMAP-CE (US EPA, 2023)

The BenMAP model allows for economic calculations to be performed using the preferred formulation method. In the case study, the valuation function employed follows the same methodological approach as in the Santiago case scenario. Because of this, 2010 was selected as the base year for data adaptation. The primary reason for choosing this year is the availability of a wide range of required data from the World Bank database. In summary, the U.S. dollar index for 2010 was used as the basis for calculating the economic outputs and economic valuations employed in this study for the year 2023. Assuming that ϵ , the income elasticity of the Value of a Statistical Life (VSL), the sensitivity of VSL to changes in income is constant both across countries (ϵ_1) and over time (ϵ_2), the equation simplifies to Equation (1), with Equation (2) representing the corresponding adjusted form.

$$VSL_{Türkiye,2023} = VSL_{US,1990} * \left(\frac{Y_{Türkiye,1990}}{Y_{US,1990}} \right)^{\epsilon_1} * \left(\frac{Y_{Türkiye,2023}}{Y_{Türkiye,1990}} \right)^{\epsilon_2} * PPP_{1990} * \frac{CPI_{Türkiye\ 2023}}{CPI_{Türkiye\ 1990}}$$

(1)

$$VSL_{Türkiye,2023} = VSL_{US,1990} * \left(\frac{Y_{Türkiye,2023}}{Y_{US,1990}} \right)^{\epsilon} * PPP_{1990} * \frac{CPI_{Türkiye\ 2023}}{CPI_{Türkiye\ 1990}} \quad (2)$$

Most of the economic data required for the analysis were obtained from the World Bank database. However, the most recent data for GDP per capita (constant 2010 US\$) were only available up to the year 2019. Therefore, the GDP per capita value for 2023 was estimated by projecting the missing years based on Türkiye's annual GDP growth rates published by the IMF. The economic parameters used in the model are presented in Table 1. In this study, Kocaeli districts were examined to highlight the potential health and economic benefits under a case scenario where PM10 concentrations are reduced by 50%.

Table 1. Economic data of Türkiye used in BenMAP-CE

Country	Year	VSL (Mean)	GDP PER Capita (Constant 2010 US \$)	PPP (Turkish liras per international \$)	Consumer Price Index (2010 = 100)
United States	1990	\$4,800,000	\$36,312	-	-
Türkiye	1990	-	\$6,774	0.0012	0.0716
	2023	Estimated by equation	\$18,782	7.3503	834.5931

RESULTS AND DISCUSSION

The Kocaeli region shows variation in land area and population distribution. In addition, air pollution in Kocaeli can be caused by both local sources and the transport of pollutants from the other territories. In this study, air pollutant data were mostly obtained based on measurements from air quality monitoring stations. Air pollution levels reduction in Kocaeli show that PM10 varied the most in İzmit and Cayirova, ranging from 18.85 to 25.64 $\mu\text{g}/\text{m}^3$ (Figure 5). Apart from Kandira, the other districts showed relatively similar average PM10 concentration levels. Gebze and Dilovasi, which are important districts known for their large populations and heavy industry, had PM10 levels ranging from 13.06 - 16.11 $\mu\text{g}/\text{m}^3$.

Figure 7. Air quality provinces map of Kocaeli

As a result of the model predictions, avoidable deaths due to cardiovascular and respiratory causes are showed in Figures 6 and 7. According to the data obtained from TURKSTAT, the number of deaths attributed to cardiovascular diseases is higher than those related to respiratory diseases. Therefore, BenMAP-CE predicted a higher reduction in deaths from cardiovascular disease compared to respiratory. When the overall mortality estimates (Figure 8) are examined, the most significant reduction in deaths observed in Izmit, Gebze, and Darica. In this study, based on the 2023 model data, the results show that the highest estimated avoidable mortality predicted Izmit, Gebze, and Darica. The main reason these three regions stand out is primarily due to PM pollutant. As shown in Figure 5, the case scenario of PM pollutant is reduced by 50%, the most significant decrease also occurs in these regions. Additionally, mortality and population rates further support these outcomes. Exposure to cardiovascular and respiratory risks is closely linked to air pollution. Over the past five years, the year 2023 recorded the highest annual average concentration of particulate matter in the Kocaeli region, with a value of $56.61 \mu\text{g}/\text{m}^3$, according to data from AQMS (Kocaeli 2023 Environmental Status Report, 2024). However, it is difficult to understand past data due to the inclusion of the COVID-19 time, and the most recent “Kocaeli 2024 Environmental Status Report” has yet to be released. Based on the available data, 2023 appears to be the year with the highest recorded PM pollution levels. AQMS in the Kocaeli region conduct measurements based on prevailing environmental conditions. In particular, variables such as wind speed and rainfall considerably impact the observed pollutant concentrations. The Kocaeli region is predominantly affected by northerly winds, and this prevailing wind direction has remained consistent over long-term wind patterns. Rainy days also positively affect the removal rate of airborne pollutants. In this study, to help make sense of the findings, number of rainy days and average rainfall over the past five years were taken from Station 17066. In the Kocaeli region, 146 rainy days were recorded, with an average daily rainfall of 6.62 mm. In previous studies, Ouyang et al. (2015) examined the impact of rainfall on PM_{2.5} levels and found that even 5 mm of rainfall could reduce the pollutant by $10\text{--}30 \mu\text{g}/\text{m}^3$. Similarly, Bodor et al. (2025), in a study conducted in Romania, observed a decrease in PM₁₀ concentrations on rainy days. Since both the number of rainy days and total rainfall amounts have remained relatively stable over the last five years, it can be concluded that the effect of rainfall on pollutant levels has shown similar behavior each year (Table 2).

Table 2. Kocaeli 17066 meteorological station of rainy days

Year	Rainy Days	Rainfall (mm)
2019	124	6.59
2020	130	5.33
2021	150	5.69
2022	133	5.05
2023	146	6.61

Figure 8. Cardiovascular model predicted map of Kocaeli districts

Figure 9. Respiratory model predicted map of Kocaeli districts

Figure 10. Predicted of reducing mortality map

The results of the economic impacts showed that in the Figure 9. Health effect costs are estimated based on air quality, mortality or incidence rates, and population data. Model results indicated that the highest economic impact occurred in Izmit, followed by the Gebze region. Another notable area is Dilovasi, which exhibited a low economic benefit due to its relatively lower population density compared to other districts. All of the BenMAP-CE model results were given in Table 3 Limited research has been conducted on the socio-economic benefits of improved air quality in the Kocaeli region. Thus, the model results are validated using data from the Santiago scenario. Accordingly, the data obtained for Kocaeli were directly adapted to the model's formulation without modification. In this study, the improvements in model predictions were based on an assumed 50% reduction in pollutant levels to explore possible outcomes under a representative scenario. Consequently, if pollutant levels in the region stay the same or increase, the model is expected to give higher estimates. According to the "Kocaeli 2023 Environmental Status Report", it was stated that climate change action plans would be developed within the scope of the 2019–2023 strategic plan. To reduce air pollution, the focus was on stopping leaks, using continuous monitoring systems, and controlling emissions during loading and unloading. Based on this report, current control measures and European Union (EU) air quality alignment efforts are expected to lower pollutant levels in the Kocaeli region; however, no specific or numerical data has been published yet. In the current situation, industrial activities in Kocaeli are continuous, and new areas continue to appear. If no further mitigation steps are taken, the economic losses caused by air pollution in the region are likely to grow even further.

Figure 11. Predicted valuation of health costs

Table 3. BenMAP-CE predicted results of Kocaeli districts

Number	Kocaeli Districts	Avoided of Cardiovascular Deaths	Avoided of Respiratory Deaths	Total Avoided Death Cases	Valuation of Prevented Expenses
1	Izmit	102	50	152	6.5 billion \$
2	Derince	12	6	18	718 million \$
3	Gebze	34	14	48	2 billion \$
4	Golcuk	11	6	17	681 million \$
5	Kandira	3	2	5	178 million \$
6	Karamursel	3	2	5	174 million \$
7	Korfez	12	5	17	708 million \$
8	Basiskele	5	3	8	268 million \$
9	Cayirova	5	2	7	289 million \$
10	Darica	15	6	21	860 million \$
11	Dilovasi	1	1	2	25 million \$
12	Kartepe	7	4	11	418 million \$

CONCLUSIONS

In this study, the BenMAP-CE model was employed to evaluate the potential health and economic impacts of the Kocaeli case scenario, in which air pollution specifically PM₁₀ is reduced by 50%. The required input data for the model were obtained from AQMS, and the WRF-Chem model results were used for missing data and stations. Due to the inadequacy of local data availability, missing parameters were obtained from the Santiago scenario provided in the BenMAP-CE training materials. Kocaeli is among the most significant provinces in Türkiye in terms of both economic and population density. The results of this study show that, improvement of air quality scenario, a considerable number of premature deaths could be prevented, which would consequently reduce associated economic losses. Izmit and Gebze areas were particularly prominent in the model predictions and should be considered as

priority areas compared to other districts. Although the model estimated lower health and economic impacts for some districts such as Dilovasi due to relatively less mortality. This situation is not to be underestimated. Because the Dilovasi district hosts a large industrial zone and many people work there during the day, it is considered a critical area for air pollution risks. The model predictions were mostly based on official mortality data and also included records from hospital administrations. However, illness cases were obtained from only one hospital, so the evaluation was primarily based on mortality data. Therefore, the number of cases is an important parameter, given that particulate matter pollutants are capable of causing both acute and chronic health effects. It is possible to reduce air pollution in the local region. However, the main problem is the source of the pollution, as pollutants can originate from either local sources or long-range transport. Local sources of pollution can be controlled, but long-range pollution transport cannot be prevented. Therefore, both anthropogenic and natural events, especially large-scale dust events such as Saharan dust can significantly affect air quality through atmospheric transport, and this makes it difficult to control air quality. Kocaeli region is an important area that requires special attention due to environmental and health issues. Therefore, air pollution in Kocaeli requires further research, particularly studies that examine both local sources and long-range pollution transport.

ACKNOWLEDGEMENTS

This study was prepared within the scope of BAP Project No. FKA-2024-3873 and is supported by Kocaeli University. Authors would like to thank to Kocaeli University for financial support. Special thanks to TURKSTAT and Kocaeli Research Hospital for their valuable contribution of health data.

ABSTRACT

With the rapid expansion of applications across various fields, particularly in biology for the development of antibacterial agents, new high-performance strategies are attracting growing attention, especially when based on materials synthesized at the nanoscale. At this scale, the emergence of novel phenomena such as superparamagnetic and an increased specific surface area endows these materials with unique functional properties. These properties are strongly influenced by the morphology, size, and structural organization of the nanoparticles. In the present study, particular emphasis was placed on evaluating the morphology, crystallinity, and purity of magnetite synthesized under varying conditions of temperature, pH, and reaction time, using two distinct synthesis methods: chemical precipitation and solvothermal synthesis. Scanning electron microscopy (SEM) analyses revealed that the synthesis route plays a crucial role in determining both the shape and size of the resulting nanoparticles. Specifically, chemical precipitation tends to produce cubic and hexagonal morphologies, while solvothermal synthesis predominantly yields quasi-spherical particles. X-ray diffraction (XRD) and Raman spectroscopy analyses confirmed that the obtained powders were primarily composed of pure magnetite. However, slight oxidation of the precipitated magnetite into maghemite ($\gamma\text{-Fe}_2\text{O}_3$) was detected in certain samples.

Keywords: Magnetite, Spinel, Nanoparticles, Magnetic Properties.

INTRODUCTION

Magnetite (Fe_3O_4) is among the most extensively studied materials owing to its remarkable electrical and magnetic properties [1, 2]. Recognized as the first known magnetic substance, it serves as a model compound for the investigation of magnetic phenomena. At the nanoscale, magnetite exhibits superparamagnetic behavior when particle size is sufficiently reduced. It is now well established that the size reduction of nanoparticles induces quantum effects, which in turn lead to significant alterations in their magnetic properties [3–5].

Although magnetite remains highly relevant in catalytic applications, it has been attracting increasing interest in various fields, particularly in magnetic storage and biomedical applications. These include its use as an antibacterial agent, in bone tissue engineering, in magnetic resonance imaging (MRI), and as a therapeutic agent in cancer treatment, owing to its excellent biocompatibility and low toxicity. The broadening of its application scope calls for comprehensive research based on innovative approaches and diverse experimental techniques to gain deeper insight into its physical, thermal, magnetic, and optical properties. Recent studies have primarily focused on the control of synthesis conditions and the investigation of novel properties tailored to the demands of emerging technologies [10, 11].

In recent years, extensive efforts have been devoted to optimizing synthesis methods to achieve precise control over the size, shape, crystallinity, and stability of magnetic nanoparticles. Consequently, a variety of synthesis routes have been developed to produce magnetite nanoparticles ranging from 25 nm to several hundred nanometers in size. These include coprecipitation, micro- and nanoemulsion techniques, green (biosynthetic) methods, and solvothermal approaches [12, 13].

Among the various methods for synthesizing magnetite (Fe_3O_4) nanoparticles, thermal decomposition in high-boiling organic solvents has proved particularly effective for producing very small nanospheres, typically between 4 and 30 nm in diameter. However, this technique has certain limitations, not least the difficulty of precisely controlling the reaction temperature, which is a major obstacle to large-scale production [14]. In addition, Fe_3O_4 nanoparticles are highly prone to oxidation, which compromises their long-term stability. For this reason, many studies emphasize the importance of coating these nanoparticles with protective layers, particularly in biomedical applications, in order to improve their chemical stability and prevent their oxidative degradation [15].

Currently, many studies have been conducted and are ongoing on Fe_3O_4 nanoparticles. These investigations have demonstrated that solvothermal and micro/nano-emulsion methods are preferred routes for obtaining crystalline spherical nanoparticles with controlled sizes and shapes, excellent magnetic properties, and low susceptibility to oxidation. Researchers have focused on solvothermal methods to maintain competitiveness in biotechnological applications. These approaches are recommended for various biomedical applications, such as targeted drug delivery (TDD) and magnetic hyperthermia therapy (MHT) [16-18].

Despite their potentially higher cost, solvothermal methods provide unmatched versatility in the fine control of reaction conditions. Derived from hydrothermal synthesis, they involve organic solvents under vacuum or inert gas to form precursors under controlled temperatures and pressures. These techniques enable not only the formation of spherical nanoparticles but also a variety of complex structures, such as cubes, sheets, rods, and single-crystal nanoplates of triangular or hexagonal geometry [3].

In this study, two simple methods were used to synthesize Fe_3O_4 nanoparticles: the co-precipitation method and the solvothermal method. A detailed structural analysis, based on commonly used characterization techniques such as X-ray diffraction (XRD), differential scanning calorimetry coupled with thermogravimetric analysis (DSC–TG), field emission scanning electron microscopy (FESEM), and Raman spectroscopy, provided essential information about their microstructural and physical properties, particularly their magnetic and optical characteristics.

MATERIAL AND METHOD

2.1 Materials

Ferric chloride hexahydrate ($\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$, 97%), cobalt acetate tetrahydrate, sodium hydroxide (NaOH) were acquired from Alfa Aesar, Sigma-Aldrich Aragonese, respectively. While ethylene glycol (EG) and ammonium acetate (NH_4Ac) were purchased from Biochem Chemopharma.

All the chemical reagents and solvents are of analytical grade and utilised without further purification.

2.2 2.2 Synthesis

Figure 1: Precipitation Synthesis

Figure 2: Solvothermal Synthesis

RESULTS AND DISCUSSION

3.1 Structural Properties

The X-ray diffraction patterns of Fe_3O_4 powders synthesized via solvothermal and precipitation methods are presented in Figure 3. The diffraction peaks were indexed with reference to the standard magnetite phase Fe_3O_4 (PDF card No. 01-075-0033), with a lattice parameter (see Table 1) closely matching the reported value for magnetite (8.39 Å) [19]. The combination of the main peak position, the refined lattice parameter, and the characteristic black color of the nanoparticles confirms the successful formation of magnetite, which crystallizes in a cubic spinel structure corresponding to the **Fd-3m** space group. Table 1 summarizes the average lattice parameters and crystallite sizes of both powders, calculated from the five most intense reflections using the Scherrer equation:

$$D = B\lambda / \beta \cos \theta$$

Where, D is the average size of the crystallites responsible for the peak, B is Scherrer's constant (0.89), λ is the wavelength of the X rays beam (1.54056 Å), β is the full width at half height of the diffraction peak, and θ is the Bragg angle.

The magnetite particles synthesized by the solvothermal and precipitation methods exhibit average crystallite sizes of approximately 11 nm and 27 nm, respectively, confirming the nanometric nature of the obtained crystallites.

Table. 1 Lattice parameters and average crystallite size of Fe_3O_4 powders synthesized via solvothermal and precipitation methods

Sample	Average grain size (nm)	Lattice parameter (Å)
Fe_3O_4 (Solvothermal)	10.4	8.388
Fe_3O_4 (Precipitation)	27.1	8.39

Figure 3: XRD diffractogram of magnetite synthesized by precipitation and solvothermal methods.

3. 1 Analyse Thermique

Coupled DSC–TG thermal analysis, carried out in the temperature range of 0 to 550 °C on magnetite powders synthesized by solvothermal and precipitation methods, was performed to characterize the thermal transformations of iron oxides and to assess their thermal stability. For both samples, the resulting thermograms exhibit three distinct thermal events, each corresponding to characteristic transitions associated with specific oxidized phases of iron (Figures 4).

The first stage, observed at temperatures below 200 °C, exhibits contrasting behaviors depending on the sample composition.

Figure 4: DSC/TG curves of magnetite synthesized by precipitation and solvothermal methods.

In the case of magnetite synthesized by the solvothermal method, the DSC curve reveals a distinct exothermic event centered around 64 °C, which coincides with a slight mass gain (1.05%) observed on the TGA curve (Figure 4). This event is most likely associated with the initial surface oxidation of Fe^{2+} ions to Fe^{3+} , marking the onset of the transformation of magnetite into maghemite ($\gamma\text{-Fe}_2\text{O}_3$), an intermediate phase frequently identified prior to the formation of hematite ($\alpha\text{-Fe}_2\text{O}_3$). The observed mass increase is attributed to oxygen adsorption on surface sites deficient in Fe^{3+} , a process favored by the strong affinity of magnetite for oxygen at low temperatures [20].

Pour la magnétite synthétisée par la méthode de précipitation, la première étape se traduit par une perte de masse de 1,81 % sur la courbe TG, attribuée à un processus de déshydratation ou à un dégagement gazeux. Parallèlement, la courbe DSC présente un pic exothermique modéré centré à 90 °C, indiquant une réaction d'oxydation interne (Eq. 1). Ces résultats sont cohérents avec la transformation progressive de la magnétite (Fe_3O_4) en magnémitite ($\gamma\text{-Fe}_2\text{O}_3$), un processus exothermique pouvant se produire sans variation de masse détectable à cette échelle de mesure.

The second thermal stage, occurring between 200 and 450 °C, is characterized by a mass loss of 3.91% for magnetite obtained by precipitation and 1.79% for that synthesized via the solvothermal route. This stage is associated with a pronounced exothermic signal, indicative of the internal oxidation of magnetite. In the solvothermal sample, the signal appears as a sharp peak centered at 265 °C, whereas in

the precipitation sample it takes the form of a broad band with a maximum at 273 °C. This behavior corresponds to the structural transformation of maghemite ($\gamma\text{-Fe}_2\text{O}_3$) into hematite ($\alpha\text{-Fe}_2\text{O}_3$) [21].

Despite their distinct thermal behaviors, both samples undergo the onset of structural transformation to hematite at an unusually low temperature of about 150 °C.

During the third thermal stage, spanning 450 °C to 550 °C, the two samples display distinct behaviors. For magnetite synthesized by the precipitation method, the TG curve reveals a relatively stable mass. In contrast, the sample produced via the solvothermal method exhibits a continuous mass loss, attributed to the evaporation of residual ethylene glycol used as a solvent during nanoparticle synthesis. These results indicate the completion of the oxidation process, culminating in the formation of a thermally stable iron oxide, identifiable by the characteristic reddish-brown color of hematite (Figure 5).

Figure 5: Visual appearance of the powder after thermal analysis (DSC/TG)

3.3 Morphological properties

The size and morphology of Fe_3O_4 nanoparticles synthesized via coprecipitation and solvothermal methods were investigated using field emission scanning electron microscopy (FE-SEM). The representative SEM image of the nanoparticles produced by coprecipitation (Figure 6) reveals faceted, cube-like aggregates, whereas those obtained via the solvothermal route exhibit quasi-spherical aggregates. In both cases, the aggregate sizes can reach approximately 100 nanometers [22–25].

The particle size distribution was determined using ImageJ software based on measurements of 200 individual particles. For the coprecipitation method, the average particle size was estimated at approximately 62.5 nm, which is slightly larger than the value obtained by X-ray diffraction (XRD). In contrast, the nanoparticles synthesized via the solvothermal method exhibit an average size of 11.2 nm, showing excellent agreement with the XRD results.

Figure 6a: Hydrothermal

Figure 6 a: Precipitation

3.4. Raman spectroscopy analysis

Due to the wide variety of magnetite crystal structures reported in the literature [26–32], the spinel structure was selected as a reference for conducting symmetry analyses and assigning phonon modes. A comprehensive examination of the symmetry properties of the inverse spinel structure, described by the cubic space group $Fd3m$ (O^7_{Fh}), enables the prediction of five Raman-active modes, summarized by the following representation:

$$\Gamma = A_{1g} + E_g + 3T_{2g}.$$

Figure 7 presents the spectral deconvolution of the Raman spectra of nanoparticles synthesized by both methods, represented as Gaussian bands within the 150–800 cm^{-1} range. Four distinct peaks are observed at approximately 180, 330, 500, and 666 cm^{-1} for both samples. In agreement with the literature, the bands at 180 and 500 cm^{-1} , assigned to T_{2g} symmetry, correspond to the asymmetric vibrations of Fe^{3+} and O^{2-} in tetrahedral sites, and are designated as the $T_{2g}(1)$ and $T_{2g}(2)$ modes, respectively. The bands at 330 and 666 cm^{-1} are attributed to the E_g and A_{1g} modes: the former arises from symmetric and asymmetric bending of oxygen atoms around iron, while the latter corresponds to the symmetric stretching of Fe–O bonds within the same sites [23, 24].

In addition to the main bands, a shoulder at 718 cm^{-1} , characteristic of maghemite, is observed in both spectra. Furthermore, additional bands at 258, 287, and 600 cm^{-1} are present in the spectrum of the powder obtained by co-precipitation. These bands, attributed to hematite, indicate oxidation of magnetite.

As hematite, the most stable phase of iron oxides, was not detected by XRD, it is likely that its formation occurred during the micro-Raman analysis. This is plausible given that the laser beam was focused on an area only a few micrometers in diameter, which can cause a local temperature rise of several hundred degrees [33].

Figure 7: Raman spectra of magnetite synthesized using precipitation and solvothermal methods.

CONCLUSION

This work focuses on the controlled synthesis of nanomaterials using two distinct approaches: precipitation and solvothermal synthesis. Structural (XRD, SEM, DSC-TG) and physical (Raman) characterization confirmed the successful production of pure magnetite nanoparticles, with the smallest particle sizes achieved via the solvothermal route. Results from XRD, SEM, and Raman analyses underscore the decisive role of the synthesis method in determining the morphology, size, purity, and stability of the magnetic nanoparticles.

ABSTRACT

Leaf senescence represents the final phase of development, culminating in cell death. While leaf senescence poses challenges in the post-harvest lifespan of horticultural plants and the yield of agricultural plants, it plays a crucial role in facilitating the re-mobilization of nutrients within plants. Various factors can influence the regulation of leaf senescence. The natural senescence of the leaf starts and progresses according to a regular schedule. During senescence, morphological and physiological events occur along with intracellular changes. Despite this, these processes have not been thoroughly explored across many species. The snapdragon (*Antirrhinum majus* L) flower serves as a valuable model system that has been extensively studied in terms of genetic traits, flower development, and cellular death. However, the senescence of its leaves has not been investigated. This study delved into the morphological attributes of senescing snapdragon leaves and revealed significant alterations in various indicators as senescence progressed. The results indicated that many indicators changed significantly with the onset and progression of senescence. Notably, there were significant decreases in fresh and dry weight, photosynthetic pigment levels, total soluble protein content, and chloroplast numbers per cell. Conversely, ion leakage and the incidence of dead cells increased with the progression of senescence. Trypan blue staining elucidated that cell death initiation occurred at the leaf tip, progressing to encompass all cells within the leaf blade during the later stages of senescence.

INTRODUCTION

Leaf senescence, the final stage of leaf development, is associated with a wide range of morphological, physiological, biochemical, cellular, and molecular changes. Leaf senescence includes changes in leaf color, chlorophyll degradation, breakdown of macromolecules, changes in the intracellular organelles, recycling of nutrients, and the activation of senescence-associated genes (SAGs), and it mainly starts with changes in developmental age (Guo, 2019).

The initial indications of leaf senescence become apparent through changes in leaf color (Zhao et al., 2018). Following a period of rapid expansion and achieving full maturity, a leaf initiates the senescence process, influenced by either the leaf's age or developmental stage or by environmental factors. Typically, the first signs of senescence involve the yellowing of the leaf tip, which gradually spreads inward towards the leaf blade. Eventually, the entire leaf blade takes on hues of yellow, orange, or purple, and the leaf dries up and shrinks, ultimately leading to cell death (Lim et al., 2007; Woo et al., 2018; Zhao et al., 2018).

Senescence is inevitable in all organisms. However, it can be delayed. The delay in senescence can be important in agricultural and horticultural crops in terms of yield and shelf life of crops. It can also impact carbon and nitrogen consumption in plants (Liang et al., 2014). Studies have indicated that senescence syndrome can be evaluated with morphological and physiological changes such as pigment content, nutrient content, ion leakage, and organelle structure. Age-related senescence is different in plant species. At different levels, leaf senescence has been investigated in a few model plants such as *Arabidopsis thaliana* (Buchanan-Wollaston et al., 2005). Therefore, an accurate description of leaf senescence using quantitative methods is very important in other plant species.

For many years, snapdragon (*Antirrhinum majus* L.) has been used as a model system for genetic studies and flower development (Lian et al., 2020; Rabiza-Świder et al., 2020). Recently, its petals have been considered in the evaluation of the programmed cell death (Roghayeh Nabipour Sanjbod et al., 2023a, 2023b). However, there is still no information about the senescence of its leaves. In this study, age-related senescence in snapdragon leaves will be investigated through some basic methods.

MATERIAL AND METHOD

This experiment was conducted at the University of Mohaghegh Ardabili, Ardabil, Iran in 2021 to investigate the leaf senescence of snapdragon. The F₁ seeds of snapdragon (*Antirrhinum majus* cv. Legend White) were purchased from the Takii seed company. The seeds were germinated in Petri dishes (20 °C, LED light, 3000 lux intensity) and sown in plastic pots (length = 18 cm and height = 15 cm) after the selection of coeval germinated seeds. The mixture of pot soil was vermicompost and complete organic fertilizers (3:1). The snapdragon plants were transferred to a greenhouse with standard conditions (15-18 °C, natural daylight) and were grown in December. The irrigation of pots was once every 2 days. Leaf longevity was divided into ten time points and the sampling of leaves was performed at these stages (days 18, 32, 46, 60, 74, 88, 102, 116, 130, 144). The first leaf was analyzed at each time point.

The measurement of fresh and dry weight was performed with a digital Micro Balance (Semi-Micro Analytical Balances GR-200, A&D Company, JAPAN). The samples were dried in an oven (60 °C, 48 h).

For investigation of electrolyte leakage, the leaf segments (squares of 1 × 1 cm) were immersed in deionized water (10 mL) and then placed in a water bath (25 °C, 30 min). After the measurement of initial conductivity (using conductivity meter, WTW InoLab Cond 720 Conductivity Meter, Carl Stuart Limited Company, UK), the samples were incubated in a water bath of 96 °C for 15 min. Then, the total conductivity was calculated and expressed as the percentage of the initial conductivity versus the total conductivity.

The content of chlorophyll and carotenoid was evaluated with the Lichtenthaler method (Lichtenthaler and Buschmann, 2005; Lichtenthaler and Wellburn, 1983). The pigment absorption was determined at three wavelengths (470, 645, and 662 nm) using a spectrophotometer (SP-UV 200, Spectrum Instruments Limited, Australia). The concentration of pigments was calculated using the following equation.

$$C_a (\mu g/ml) = 11.24 \times A_{661.6} - 2.04 \times A_{644.8}$$

$$C_b (\mu g/ml) = 20.13 \times A_{644.8} - 4.19 \times A_{661.2}$$

$$C_{(x+c)} (\mu g/ml) = \frac{(1000 \times A_{470} - 1.90C_a - 63.14C_b)}{214}$$

The leaf samples were fixed in 3.5% (v/v) glutaraldehyde for 1 h in the dark for chloroplast number per cell area. The samples were washed with Na₂EDTA buffer (0.1 M, pH=9) and kept in this buffer. The samples were then placed in a shaker water bath (60 °) for 2.5 h and stored at 4 °C. The pictures of leaf samples were taken by light microscopy. Image J software was applied for quantification of chloroplast count (Evans et al., 2010).

For soluble protein, the leaf tissue (100 mg) was homogenized in phosphate buffer (pH=7) and centrifuged at 10000 rpm (10 min) at 4 °C. The supernatant (100 µL) was separated and mixed with Coomassie solution (5 mL). After vortexing, absorbance was read at 595 nm. BSA standard curve was applied for the calculation of total soluble protein (Roghayeh. Nabipour Sanjbod et al., 2023).

Dead cells of snapdragon leaf were detected with trypan blue staining. For this purpose, the excised leaves were placed in trypan blue staining solution at 96 °C for 1 min. The samples were left at room temperature for 1-24 h. The staining solution was removed and the samples were immersed in chloral hydrate solution for 2–4 h. After that, the chloral hydrate solution was removed and the samples were placed in 70% glycerol. The staining of leaves was recorded by taking pictures (Guo, 2019).

This experiment was conducted as a completely randomized design (CRD) with five replications and analyzed using SPSS software (version 16; SPSS Inc, USA). The means were evaluated with Duncan's multiple-range tests at 5% probability.

RESULTS AND DISCUSSION

The results of this study showed that with increasing age of the plant, fresh and dry weight increased and reached the maximum value on day 60, then with the onset and progression of senescence, a severe decrease in these parameters was observed, which was visually associated with leaf desiccation (Figure 1A and 1B). Interestingly, the leaves had the highest ion leakage on day 18 in electrolyte leakage. Gradually, with increasing age, ion leakage decreased. On the 88th day, an increase in electrolyte leakage was observed, which coincided with the progress of senescence and the beginning of cell death. After that, ion leakage decreased in the stage of leaf shriveling and desiccation (days 116, 130, and 144) (Figure 1C). The highest content of photosynthetic pigments was observed on the 46th day. After that, the content of chlorophyll a, chlorophyll b, and total carotenoids gradually decreased. (Figure 1D, 1E and 1F) The examination of the total soluble protein content showed that with increasing age and reaching day 88, this parameter increased with a gentle slope, and then with the onset of cell death, cell proteins were broken down and their content significantly decreased (Figure 1G). The highest number of chloroplasts per cell was recorded on the 46th day and their number decreased in the following days (Figure 1H). Trypan blue staining showed that the number of dead cells increased with increasing age. Furthermore, the death of the cells started from the tips and margins of the leaves and gradually the whole leaf cells experienced death (Figure 2).

Figure 1. Progression of cell death in snapdragon leaves.

Leaves, as specialized organs for photosynthesis, require considerable energy and nutrients for production; following a productive period, leaves enter senescence where nutrients are redistributed to younger leaves, seeds, or stored for future growth, resembling a recycling program at the organismal level (Quirino et al., 2000).

The senescence of leaves can be discerned through alterations in their appearance. The initial visible indications of leaf senescence involve changes in leaf color. Following growth and maturation, a leaf enters the senescence phase. In typical circumstances, the initial signs of senescence with the yellowing of the leaf tip, progressing gradually towards the leaf blade, eventually resulting in the entire blade, followed by leaf desiccation and shrinkage, culminating in cell death (Guo, 2019) as observed with trypan blue staining.

Chloroplasts are among the primary organelles targeted for degradation at the onset of senescence. Similar to our findings, the loss of chlorophyll is a noticeable occurrence during senescence and is frequently used as a biomarker for the start of senescence. On the other hand, numerous other breakdown processes such as protein, lipid, and nucleic acid degradation also happen (Zhao et al., 2018).

Protein degradation represents a crucial process during leaf senescence, playing a pivotal role in nitrogen recycling. Studies at the transcriptomic level have revealed a significant upregulation of genes related to proteolytic activities (Breeze et al., 2011). Predominantly, serine proteases and CysProt enzymes are prominently associated with leaf senescence, although aspartic, threonine, and metalloproteases have also been identified (Diaz-Mendoza et al., 2016). Plant protease activities have been identified in various cellular compartments such as nuclei, chloroplasts, cytosol, ER, vacuoles, mitochondria, apoplast, cell wall, and specialized vesicles (Diaz-Mendoza et al., 2016). The chloroplast stands as the primary reservoir of mobilizable proteins within the cell, with Rubisco and the chlorophyll-binding light-harvesting proteins of PSII (LHCIIIs) being the major proteins (Hörtensteiner and Feller, 2002). Chloroplast proteins account for up to 80% of the total leaf nitrogen and serve as a key nitrogen source during mobilization from senescing leaves. Throughout senescence, chloroplast proteins are believed to undergo degradation through coordinated actions of chloroplast proteases, senescence-associated vacuoles (SAVs), and the ubiquitin/26S proteasome pathway (Diaz-Mendoza et al., 2016).

CONCLUSIONS

The findings revealed that several markers experienced significant alterations as senescence began and developed. Noteworthy was the considerable reduction in both fresh and dry weight, levels of photosynthetic pigments, total soluble protein content, and the number of chloroplasts per cell. In contrast, there was an increase in ion leakage and the prevalence of dead cells as senescence progressed. Analysis with trypan blue staining showed that the initiation of cell death occurred at the tip of the leaf, extending to encompass all cells in the leaf blade in the advanced stages of senescence.

ABSTRACT

While human beings struggle to survive in a globalizing world, nature has managed to exist on its own and has solved its problems within itself. Animals, plants, decomposers and even microbes have found their place in this order and become part of the solution. Thanks to this harmony of nature, studies conducted over the last twenty years have yielded information that can guide ecosystems, cities, architects and interior designers. Although the operation of biomimicry design may sound complicated, it is actually quite simple. Biomimetic design includes inventions and designs that are inspired by solutions developed by nature and provide sustainable solutions. Especially as we move into an ecological age that embraces nature rather than overcoming it, looking at it from a biomimicry perspective becomes meaningful. This perspective suggests acting like nature and approaching problems like nature, beyond simply coexisting with nature. In this study, the importance and examples of biomimicry, which encourages innovation in design and brings new perspectives to existing problems, are discussed.

Keywords: Biomimicry, Inspiration from nature, Sustainability

INTRODUCTION

The reason why the "eco-centric" approach came to the fore in the 20th century is today's "unsustainable" patterns. Sustainability is a widely accepted moral principle that emerged within the environmental movement and whose content is constantly being redefined within the political process (Tekeli, 2001). Although the concept developed in connection with the discussions around the concept of "eco-development" included in the Report of the World Environment Conference held in Stockholm in 1972, it is known that the questioning of the human-living environment goes back much further.

Since the day human beings came into being, they have tried various ways to find solutions to the problems they have encountered. Issues such as the ever-increasing world population, rapid industrialization, excessive fossil fuel use, and environmental destruction have become major global problems. In addition to being able to quickly find solutions to all these problems, the most important goal should be that these solutions are sustainable and support the ecological structure. Taking into account and researching thousands of years of experience of nature to find solutions to human problems and needs may be the answer to many of the problems we experience. The concept of biomimicry or biomimetics, a new innovation discipline, is defined as a 'multidisciplinary design approach' or 'a new relationship with nature' (Caferoğlu, 2021). Biologist Benyus (2002) first used the concept of biomimicry in her/his book "Innovation Inspired by Nature". Biomimetic design includes inventions and designs that are inspired by solutions developed by nature and provide sustainable solutions.

1. What is Biomimicry?

The environmental problems we have faced in recent years are actually the result of the methods we have developed to make human life easier. The use of resources, vehicles and industry, which exceed the capacity of the planet, requires new solutions to be found today. This is where biomimicry comes in. Innovative projects focused on the environment and efficiency are rapidly gaining ground in human life (URL 1).

Biomimicry is derived from the Latin words *bios* (life) and *mimikos* (imitation) (Volstad and Boks, 2012). Biomimicry is actually defined as design inspired by nature to imitate life and nature (Kennedy, 2004) and is an important source of innovation. In the light of science and technology, it is an important contribution to the question of how we can do better rather than the question of how we can do it better in producing solutions to problems (Eryılmaz, 2015; Primlani, 2013).

Biomimicry, a concept related to innovative ideas inspired by nature, basically refers to the design of products and materials that produce solutions from living things in nature. Biomimicry forms the basis of many products used in fields such as architecture, artificial intelligence, robotics, industry, transportation, in short, today's technology (URL 2).

Biomimicry enables sustainable designs by taking advantage of the power of nature. It helps people produce environmentally friendly projects. Biomimicry studies, which have become especially popular recently, aim to use the world's dwindling natural resources effectively. This process, which prioritizes naturalness and has many examples in the history of science and art, can be applied to many different fields such as technology, art, transportation and energy (URL 3). Benyus divides biomimicry into three levels, and each level offers different lessons from nature.

Mimicking Form and Shape: Consider the sleek, streamlined body of a fish; engineers use this principle to shape wind turbine blades for maximum efficiency.

Mimicking Natural Processes: What matters is not how nature looks, but how it works. Take photosynthesis for example; scientists are studying how plants convert sunlight into energy, creating sustainable and renewable energy sources.

Learn from Ecosystems: Nature wastes nothing. Forests, coral reefs, and other ecosystems operate in perfect balance, with each byproduct feeding another process. Inspired by this, industries are now designing closed-loop systems where one company's waste becomes another company's raw material, attempting to eliminate pollution (URL 4).

2. What is the Aim of Biomimicry (Biomimetism)?

It can be said that the main reason why biomimicry, which we encounter in the history of science and art, has gained popularity in recent times is related to the effort to use the world's natural resources, which are decreasing day by day, efficiently. Nature is the basis of biomimicry, and sustainable designs can be created by imitating the perfect functioning of nature. The process, which draws its strength from nature, enables people to produce environmentally sensitive projects (URL 5). Biomimicry aims to create products, processes or systems that are in harmony with life and serve sustainability.

In nature, biological organisms such as animals, plants and microbes constantly improve themselves to survive and adapt to the harsh conditions of nature. Those who fail are wiped out, those who succeed survive. American biologist Janine Benyus, the first scientist to suggest that the ways in which living things adapt to life should be consciously imitated and who pioneered the idea of biomimicry in the late 1990s, says: "Nature has already solved all the challenges we face. Failures have become fossils, and what we are in now is the key to survival." (URL 6). Biomimicry, which has been growing in popularity since its inception and utilizes natural organisms to support innovation, aims to be sustainable (URL 3).

3. What are the Areas of Use of Biomimicry?

Biomimicry usage areas form the basis of many products used in fields such as industry, artificial intelligence, transportation, architecture, and robotics. Biomimicry, first proposed by American engineer Otto H. Schmitt in 1969, is credited with establishing the field of biomedical engineering.

4. Sustainability with Nature-Inspired Designs

Sustainability involves the beneficial use of design to meet current and future human needs without depleting a resource or causing permanent damage to the environment. Considering environmental awareness in product design and production processes has led to the emergence of the concept of sustainable design. Sustainable design is an approach that minimizes environmental impacts that may occur through product design while increasing innovation. Sustainability connects the present to the future and makes all humanity responsible for the environment (Caferoğlu, 2021).

Kanisanlı and Durmuş (1995) emphasize that various plants and insects avoid becoming a food chain for living things by resembling themselves to various living things and even to the environment they live in, and state that the imitation of a plant or an animal by living things in terms of both color and pattern is called mimicry. The green color of the tree frog and its resemblance to a leaf, and the bush crickets' resemblance to a bush and a tree stem are examples of biomimicry in nature. The examples of biomimicry here are imitations of living things in nature. Based on this, people's inspiration from or imitation of nature was also shown as an example of biomimicry, and there was no need for a different word for definition. This new approach aims to bring sustainable solutions to current problems that cause less harm to the planet, using the teachings of nature, by looking at the models, systems and processes in nature (Caferoğlu, 2021).

Nature is a system that has both the best design and the most efficient system. With the development of technology, man's ability to imitate nature has also increased. Sustainability is one of the fundamental goals of biomimicry. Biomimicry-inspired designs are designed to be both aesthetically pleasing and energy-efficient. The philosophy of biomimicry, like the philosophy of nature, aims to optimize resource consumption in its natural process. For sustainability, nature redesigns its own processes over time. The strongest evidence of this is that this process, which has been imitated over time, has been seen to continue effectively. Thus, the sustainability of biomimicry may vary depending on the development of designs derived from nature (URL 3).

5. Nature-Inspired Designs

Many of the design examples inspired by nature are innovative projects that reveal details that had not been considered before. Designs based on biomimicry imitate nature's efforts to create the best system with the least amount of resources. Some examples of biomimicry are presented below.

Concorde and Dolphin: The British-French joint-production Concorde aircraft, which managed to exceed the speed of sound, made its first flight attempt in 1969. The nose part of the dolphins was effective in its design, because it reduced the friction created by the air on the outer surface. Inspired by dolphins, whose tail fins act as engines on the surface of the water, engineers placed Concorde's engines at the rear (Figure 1). Production of these aircraft ceased in 2003 (Kılıç, 2022).

Figure 1. Dolphin-inspired Concorde aircraft (Kılıç, 2022)

Velcro Tape and Burdock: One day, Swiss engineer Georges de Mestral got these plants stuck on his clothes. When Mestral saw that it was not easy to separate his clothes from this plant, he immediately came up with an idea and decided to use it in the clothing industry (Figure 2). He created the same docking system and Velcro straps are now used in astronaut suits (URL 7).

Figure 2. Velcro tapes produced using burdock (URL 7)

Radar and Bat: The vibrations emitted by bats, which have poor vision, hit obstacles and bounce back, thus determining their movement style. The operation of the radar is also based on the same system (Figure 3) (URL 7).

Figure 3. Radars inspired by the vibrations emitted by bats hitting obstacles and bouncing back (URL 7)

Munich Olympic Stadium and Dragonfly's Wings: Despite being so thin, the dragonfly's wings, which are only 1/3000th of a millimeter thick, are remarkable for their durability. Their durability stems from the fact that their wings are composed of nearly a thousand segments, preventing them from tearing during flight. The roof of the Munich Olympic stadium was constructed using the same method (Figure 4) (URL 7).

Figure

4. The Munich Olympic Stadium was inspired by dragonfly wings (URL 7)

Swimsuits and Sharks: Sharks have a type of tooth structure in their skin. This structure creates a low-pressure zone as the shark moves underwater, creating vortices in the water. Thanks to the vortices that form, the shark is pushed forward powerfully and gains speed in the water. This method is also applied in professional swimming trunks (Figure 5). It allows swimmers to move faster using much less

muscle force (URL 4).

Figure 5. Professional swimming trunks inspired by shark skin (URL 4)

Eastgate Centre in Harare, Zimbabwe and Termite Mounds: Designed by Mick Pearce and opened in 1996, the Eastgate Centre has a ventilation system based on the natural cooling structure of termite nests (Figure 6). Fans draw fresh air from outside and cool it as it passes through underground channels that mimic the airflow in termite nests. Cold air circulates throughout the building, creating a comfortable indoor environment without air conditioning.

Inspired by nature, this ventilation system is more environmentally friendly, consuming only 10% of the energy used by a traditional air conditioning system. The building also features a rainwater harvesting system, solar panels for hot water, and a green roof (URL 4).

Figure 6. Zimbabwe Eastgate Centre was inspired by termite nests (URL 4)

Lotusan Self-Cleaning Paint and Lotus Flower: The Lotus Effect is essentially the self-cleaning feature found in the Lotus flower leaf. This type of effect is also found in the wings and bodies of some insects (Gruber, 2011). This knowledge has led scientists to find new materials. Lotusan is a self-cleaning paint that can be used on both interior and exterior surfaces. One of a building's biggest nightmares is moisture. This design keeps moisture away from the surfaces, allowing the building's surfaces to breathe and appear clean. Lotus leaf is known as the best waterproof material in nature. The lotus, whose surface is covered with wax secretion, is hydrophobic (water repellent) thanks to this secretion (Figure 7). The University of Bonn conducted research together with several companies and designed a paint called Lotusan, which is an adhesive film containing nanoparticles such as hydrophobic silica (Shimomura, 2010). This extremely ingenious design reveals the necessity of taking inspiration from nature (Toruç, 2021).

Figure 7. Lotus effect (Toruç, 2021)

Wind Turbines and the Humpback Whale: Another prominent example of biomimicry from real life is modern wind turbines. Inspired by the fins of humpback whales, which can reach up to five meters, wind turbine designs have various humps and irregularities called pectorals, just like these creatures (Figure 8). In this way, the efficiency of the turbines increases and the noise generated by the rotation of the turbines is greatly reduced (Kılıç, 2022).

Figure 8. Wind turbine designs inspired by humpback whale fins (Kılıç, 2022)

DISCUSSION AND CONCLUSION

Nature has a flawlessly functioning system that has solved every problem that has arisen over centuries within its own system. When nature is seen as an educator rather than a resource to be constantly consumed, its importance in the continuity of life is better realized. For the survival of the human species, existing systems that destroy nature must be changed. Biomimicry can guide us in this regard. Biomimicry is a design tool that develops sustainable solutions inspired by nature to solve a human problem or need that nature has already solved. We can get answers to many problems from nature by looking in the right places to find what we need or answers to questions (Caferoğlu, 2021).

The creative and innovative potential of biomimicry is promising for providing sustainable solutions to future environmental problems in engineering, architecture, industry and other fields. It is thought that observing and applying nature's problem-solving methods with the biomimicry approach will provide the opportunity to realize innovative materials and methods that have perhaps never been produced before, in harmony with nature (Eryılmaz, 2015).

By approaching design from a holistic perspective through biomimicry, the effects of designed products on our planet's cycles, ecosystems and economy can be positively changed during the production, consumption and waste stages. Thanks to products designed with the biomimicry approach, we can help reduce the negative impact we have on the environment.

EXPERIMENTS ON REVEALING EFFECTS OF DIFFERENT MEDIA STRENGTH, AND SUCROSE-DEPENDENT IN ADVENTITIOUS ROOT CULTURES OF RADISH (*Raphanus sativus* L.)

Tugce OZSAN KILIC

Department of Horticulture, Faculty of Agriculture, Akdeniz University, Antalya, TURKEY

ABSTRACT

Radish (*Raphanus sativus* L.), one of the important vegetables of the *Cruciferae* family, has attracted attention due to its nutritional content and health-improving properties. The adventitious root culture technique not only supports the propagation of medicinally valuable plants but also offers an alternative method to harvest valuable bioactive components from plants. In the current study, hypocotyls obtained after germination of red and black radish seeds were used as explant material, the effect of MS basic medium at different strengths ($\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and 1) and the effect of different amounts of sucrose (20, 25, 40 and 50 mg L⁻¹) on adventitious root formation were evaluated in terms of biomass formation. Within the framework of the results obtained, it is thought that adventitious root cultures of radish can be used as a complementary method in the large-scale production of valuable bio-compounds to be used in the pharmaceutical industry.

Keywords: *in vitro*, root cultures, medium strength, biomass

INTRODUCTION

Plants are used as a model system and a taxonomic marker for the discovery of new compounds. Increasing awareness of the health hazards and toxicity associated with the indiscriminate use of synthetic drugs has increased interest in the use of plants and plant-based medicines. The complex structure of the compounds and the high cost of chemicals make the synthesis of bioactive compounds a difficult process. However, the production of these compounds is also affected by some factors, such as the growing period of the plant and the season in which it is collected, species and variety differences, the plant being in a certain growth and development period, and the lack of adequate methods for the production and standardization of the plant (Ahmad et al., 2015).

As an alternative solution to such problems faced by the phytopharmaceutical industry, biotechnological approaches, especially plant tissue culture methods, attract a lot of attention. Since plant tissue culture methods offer a controlled supply of biochemicals independent of plant availability with consistent product quality, it is thought that they could provide a great potential to boost the conventional agriculture for the industrial-scale production of bioactive plant metabolites (Ramachandra Rao and Ravishankar, 2002; Ahmad et al., 2015). Plant cell, tissue, and organ culture techniques are promising techniques that have the potential to be used in obtaining valuable plant metabolites, including pharmaceuticals (Murthy et al., 2008; Ahmad et al., 2015). These techniques both provide a reliable source for plant-based pharmaceutical products and can be used for large-scale cultures of plant metabolites. The increasing commercial importance of secondary metabolites in recent years has led to great interest in the diversification of the production of bioactive plant metabolites through tissue culture technology. At this point, the adventitious root culture system provides an alternative approach for the improvement and development of plant-based pharmaceutical compounds (Ahmad et al., 2015).

Plant roots serve as a source of bioactive molecules, including a surprising variety of metabolites, agrochemicals, flavors, dyes, and fragrances (Fulzele et al., 2002). Recently, organ culture, especially adventitious root culture, has been applied to many medicinal plants due to their rapid growth as well as stable production of secondary metabolites of pharmaceutical and nutraceutical interest (Murthy et al., 2008). Adventitious roots induced under aseptic conditions in a suitable nutrient medium supplemented

with plant growth regulators have a good growth rate and have a potential for accumulation and sustained production of secondary metabolites (Hahn et al., 2003).

Adventitious root formation is a complex process involving various endogenous and exogenous factors (Sorin et al., 2005). The adventitious root formation process is divided into four stages: (a) the pre-emergence stage of the root, which includes the molecular and biochemical process changes that occur prior to any cytological formation up to the emergence of primordial roots, (b) the early stage of root development, (c) the root growth stage (weight and volume increase) and (d) the final stage of root configuration (emergence of the first root) (Zhang et al., 2017). The initiation and differentiation process during the physiological stages of rooting can be triggered by changes in endogenous auxin concentrations and external addition of specific auxins (Praveen et al., 2009).

Adventitious roots show high stability, high growth rate, and continuous secondary metabolite production when stimulated in an aseptic artificial nutrient medium supplemented with optimal phytohormone (Hahn et al., 2003). These roots produce high amounts of alkaloids, terpenoids, and phenols in cell and tissue spaces and show high stability and growth rates; they can be easily produced in a suitable hormone-supplemented environment with a low amount of inoculum (Sivakumar et al., 2006). Adventitious root cultures also provide an experimental system to study the link between primary and secondary metabolism (Ahmad et al., 2015).

Radish (*Raphanus sativus* L.), one of the important vegetables of the *Cruciferae* family, is one of the functional foods that have an important place in meeting people's fresh vegetable needs and attracts attention with its nutritional content and health-improving properties (Akan et al., 2013) such as antibacterial, antioxidant, antimutagenic, hepatoprotective, nephroprotective, antidiabetic, anti-inflammatory activities (Rosés et al., 2023).

In the current study, hypocotyls obtained from red and black radish seeds germinated *in vitro* were used as starting material, and Murashige and Skoog (MS) basic medium at different strengths ($\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and 1) and various amounts of sucrose (20, 25, 40 and 50 mg L⁻¹) were used to reveal their effect on adventitious root formation regarding biomass accumulation.

MATERIALS AND METHODS

The study was carried out in the Tissue Culture Laboratory of Akdeniz University, Faculty of Agriculture, and Department of Horticulture.

Explant and Media Preparation, Explant Culturing

Seeds of red and black radish cultivars were used in the study. Seeds of the cultivars were subjected to surface sterilization before being cultured. The seeds were first kept in 70% ethanol solution for 1 minute and then sterilized in 50% sodium hypochlorite solution for 12 minutes, and then, it was rinsed 3 times with sterile distilled water.

Sterilized seeds were cultured in MS (Murashige and Skoog, 1962) medium (MS0) containing 30 g L⁻¹ sucrose and 6 g L⁻¹ agar, without the addition of plant growth regulators, to germinate under *in vitro* conditions. Cultured seeds were incubated under 24±2 °C temperature and 16/8 hour light/dark photoperiod conditions. For seed germination under *in vitro* conditions, 15 glass jars with a volume of 660 mL were used for both cultivars, and 15 seeds were planted in each jar.

The 15-day-old hypocotyls from the germinated plantlets were used as starting material for the adventitious root culture study. Hypocotyls were cut into 0.5 - 1 cm pieces in a laminar flow and cultured in the combinations of media presented in Table 1 for the initiation of adventitious root cultures. For each cultivar, 90 mm 5 petri dishes/medium were used while 15 hypocotyl explants were cultured in each petri dish and the study was carried out in 3 replications.

Table 1. Media combinations used in the study

Media Codes	Media Combinations			
	MS	IBA (mg L ⁻¹)	Sucrose (g L ⁻¹)	Agar (g L ⁻¹)
1	$\frac{1}{4}$	2	30	6
2	$\frac{1}{2}$	2	30	6
3	$\frac{3}{4}$	2	30	6
4	1	2	30	6
5	$\frac{3}{4}$	2	20	6
6	$\frac{3}{4}$	2	25	6
7	$\frac{3}{4}$	2	40	6
8	$\frac{3}{4}$	2	50	6
Control	1	-	30	6

Establishing and Propagating of Adventitious Root Cultures

Adventitious root cultures were initiated with 2-month-old roots consisting of hypocotyl explants cultured in different combinations of media. Adventitious roots (0.15 - 0.20 g/petri) obtained from hypocotyls of black and red radish cultivars were inoculated into 100 mL conical flasks containing 30 mL of nutrient medium. The medium combinations used in the initiation of adventitious root cultures were used as liquid medium without adding agar for adventitious root propagation. Cultures were shaken at 130 rpm on an orbital shaker under dark conditions at 24±2°C for 4 weeks. Three subcultures with 4-week intervals were conducted in the study, and the weights of the proliferating adventitious roots at the end of each subculture were measured and recorded.

Statistical analysis

The experiments of the current study were conducted in three replicates with a completely random factorial design. The data obtained were made in the JMP package program and the differences between the averages were determined by the 'least significant difference' (LSD) test, and the differences were found to be statistically significant at the $p < 0.05$ level.

RESULT AND DISCUSSION

In this study, the effects of MS media of various strengths and sucrose at different concentrations on the initiation of adventitious root cultures and biomass accumulation in 2 different radish cultivars were evaluated (Figure 1 - 3).

Figure 1. Biomass accumulation in radish cultivars regarding different media and subcultures
 (1): Different letters among cultivars, media and subcultures denote significant differences (LSD test, $p < 0.05$).
 (2): $LSD_{cultivars} = 0.115$; $LSD_{media} = 0.231$; $LSD_{subculture} = 0.142$; (b) $LSD_{cult. \times media \times subc.} = 0.568$
 (3): Abbreviations; subc.= subculture; RR = Red Radish; BR = Black Radish

Figure 2. Adventitious root formation from hypocotyls of black (A) and red radish (B) cultivars in different media

Figure 3. Adventitious root cultures of black (A) and red radish (B) cultivars in different media

According to the findings, statistical differences were determined regarding biomass accumulation between radish cultivars. The responses of the cultivars to adventitious root cultures were found to be different in terms of biomass accumulation, and it was observed that the black radish cultivar provided higher biomass accumulation than the red radish cultivar.

Differences were detected in terms of the nutrient media combinations evaluated. The combination of media in which the $\frac{1}{2}$ MS strength supplemented with 30 g L⁻¹ sucrose (medium combination No. 2) gave the most positive value in terms of biomass accumulation, which was followed by the medium No. 8, contained $\frac{3}{4}$ MS strength and 50 g L⁻¹ sucrose.

Among various plant cell and organ cultures, adventitious root culture is an alternative and complementary tool to whole plant cultivation to produce high-value phytochemicals (Hao and Guan, 2011; Baque et al., 2012b; Sivanandhan et al., 2013), a wide range of physiological It has a complex molecular process involving several factors (Sorin et al., 2005).

Previous studies have reported that auxins play a very important role in the adventitious root formation process, and that exogenous auxin applications as well as endogenous auxins are important in promoting the initiation and division of adventitious roots (Baque et al., 2009; Hussein et al., 2012). Indole butyric acid, IBA, is known as synthetic auxin and is among the first plant hormones used to increase root formation in plant stems (Deloso et al., 2020). For example, in a study, it was reported that IBA was more effective than IAA and NAA in stimulating adventitious roots from hypocotyl explants of *Psoralea coryfolia* (Baskaran and Jayabalan, 2009). In current study, IBA (2 mg L⁻¹) was used and had a positive effect on adventitious root development.

Success in adventitious root cultures is affected by various factors. As stated before, in addition to the effect of auxins, the salt strength of the medium, sucrose concentration, or explant type are among the determining factors for success in adventitious root cultures.

There are many studies showing that low salt strength may boost root induction and growth. Wu et al. (2006) found that *Echinacea angustifolia* adventitious roots required low levels of ambient salt strength for the production of root biomass. Baque et al. (2010) reported that a gradual decrease in fresh and dry weight was observed as the salt strength of the nutrient medium increased in the adventitious root culture study of *Morinda citrifolia*. Zhang et al. (2011) reported that a medium containing low salt strength provided a good performance in terms of induction and growth of adventitious root cultures of *Periploca sepium*. It is thought that one reason why low salt strength produces positive results on root biomass in different plant species may be that low salt strength leads to a decrease in osmotic pressure in cultures, which may be suitable for root primordium induction and growth (Zhang et al., 2011).

Another possible reason is that favorable interactions between nutrients in low salt strength cultures make it easy ions to reach to the roots (Wu et al., 2006).

In vitro plantlets require carbon sources in their artificial media for biological processes such as survival, growth, development and accumulation of bioactive compounds under aseptic and controlled conditions. Carbohydrates are an important source of carbon and energy in plant cell and organ cultures. Sugar added to the culture medium not only acts as a carbon source but also plays a role in the osmotic regulation of water stress (Hilae and Te-chato, 2005). The growth rate of biomass is directly associated with sugar consumption. It is thought that the increase in growth in adventitious roots may be due to the adventitious roots needing high sucrose for growth at the differentiation stage and structural integrity (Tremblay and Tremblay, 1995). Muthoharoh et al. (2019) investigated the effects of different sugar types and concentrations on root biomass in *in vitro* adventitious root culture of *Gynura procumbens* (Lour) Merr. Researchers obtained the highest fresh root biomass when 5% and 3% sucrose were used as carbon sources, respectively. Similarly, Manuhara et al. (2017) reported that an increase in fresh root weight was observed by increasing sucrose concentration, and the highest root weight value was obtained with the use of 5% sucrose. In another study, Ahmad et al., (2021) reported that there was an increase in biomass accumulation in stevia (*Stevia rebaudiana*) by adding a sucrose concentration as high as 50 g L⁻¹ to the growing medium.

In an adventitious root culture study conducted by Adil and Abbasi (2019) in leaf cabbage (*Brassica oleracea* var. *acephala*) they found that the sucrose concentration significantly affected the adventitious root formation. Researchers, who revealed maximum adventitious root formation in MS medium supplemented with 40 g L⁻¹ concentration of sucrose, reported that increasing the sucrose concentration to a level higher than 40 g L⁻¹ adversely affected adventitious root formation in cotyledon explants. Similar results were reported by Wang and Weathers (2007) on *Artemisia annua* L. and by Baque et al. (2012a) on the plant *Morinda citrifolia* (L.).

Different explants, including leaves, stems, petioles, roots, and hypocotyl parts, can be used for the induction of adventitious roots *in vitro* in many industrially important plant species (Paek et al., 2009; Sharma et al., 2013; Kawakami et al., 2015; Khan et al., 2015; Khan et al., 2017; Saeed et al., 2017). For this reason, it is thought that the different results obtained in terms of biomass in adventitious root cultures of various plant species may be also due to differences in species, varieties, and explants.

CONCLUSION

In light of the results obtained from the study, differences were determined among the cultivars. Decreasing the MS strength to a certain extent or increasing the sucrose concentration added to the medium with decreasing MS strength led to an increase in the biomass obtained from adventitious root cultures in radish. Considering that adventitious root cultures are an important alternative method for producing high-value phytochemicals, it is thought that within the framework of the results obtained, adventitious root cultures of radish can be used as a complementary method in the large-scale production of valuable phytochemicals to be used in different industries such as pharmaceutical industry.

ABSTRACT

Plastics are indispensable materials in daily life due to their properties such as being easy to process, durable, lightweight and cheap. Due to its widespread use, it is also one of the biggest pollutants in terms of the environment today. It is known that the increasing use of plastic creates serious pollution, especially in oceans and seas. One of the most important plastic groups that pose a problem is microplastics, which have a high probability of being ingested into living bodies due to their size. Microplastics can be directly incorporated into aquatic ecosystems, or they can emerge when large-sized plastics break down and disperse as a result of natural processes. Microplastics have become a major threat to both aquatic organisms and human health. The interdisciplinary nature of microplastics research necessitates an approach that requires integrity that transcends scientific fields. The aim here is to raise awareness of the possibility that plastic waste that is used and thrown away and whose outcome is not considered may eventually return to the human body as microplastic. To achieve this goal, the history, classification, sources, contamination with nature, disposal methods, effects on the food chain and environmental risks of microplastics were investigated.

Keywords: Plastics, Microplastics, Ecosystem pollution, Living organisms

INTRODUCTION

Plastics are a class of long-chain organic polymers with high molecular weight (Liu et al., 2016). More than 45 different types of plastics are used in commercial production, including types such as polypropylene (PP), polyethylene (PE), polyethylene terephthalate (PET), polystyrene (PS), polyurethane (PU), polyvinyl chloride (PVC) and polycarbonate (PC) (Halıcı Demir, 2024; Kannan and Vimalkumar, 2021).

In this century where we live in the plastic age, plastics are used in every field including chemistry, materials science and the food chain, and plastics are seen as the biggest pollutants of our age. Plastic materials that have entered our lives in various ways, such as simple food packaging, synthetic fibers, car tires, and clothing containing plastic, cause irreversible environmental problems in air, water, and soil quality (Fonseca et al., 2017; Aslan, 2018). Marine environments are among the places most affected by plastic pollution. It is known that plastics, which pass into the environment in different ways, create plastic litter on ocean surfaces through precipitation and flows (Akhan et al., 2022; Yurtsever, 2018; Botterell et al., 2019).

Today, plastic pollution has become a global environmental and public health problem. According to Plastics Europe, global plastic production was 390.7 million tons per year in 2021 and only 8.3% of the production was met using recycled plastic (Plastics Europe and EPRO, 2022). It has been reported that global plastic waste production was 60 to 99 million metric tons annually in 2015, and this number will triple by 2060, reaching 155-265 metric tons (Lebreton and Andrady, 2019). It is estimated that unless effective improvements are made in existing waste treatment systems, the world's environment (land, freshwater, ocean, air) will be filled with 13.2 billion plastic wastes by 2050 (Halıcı Demir et al.,

2024; Silva et al., 2020). When we add to this the fact that petroleum-derived plastics are not biodegradable and have long-term durability, it is estimated that plastic pollution resulting from human activities will continue for centuries. Therefore, plastic and especially microplastic are considered as one of the global, environmental and economic pollutants (Botterell et al., 2019).

1. What is Microplastic?

Exposure to sunlight, oxygen reaction and physical effects of plastics of various shapes and sizes entering water resources cause them to break down into small pieces as a result of their degradation. In the early 1970s, millimeter-scale plastics were first observed in the sea and in fish (Carpenter et al., 1972). These microscopic pieces of plastic are called microplastics (Fonseca et al., 2017; Aslan, 2018; Welle and Franz, 2018). The term microplastic was first defined by Thompson et al. (2004) as plastic particles smaller than 5 mm (Andrady, 2011). This definition was developed to represent synthetic solid particles or polymeric matrices with sizes ranging from 1 μm to 1 mm, of regular or irregular shape, originating from primary or secondary production and insoluble in water (Verschoor, 2015; Lusher et al., 2017).

In a study conducted by Biber et al. in 2019, the degradation and microplastic formation potential of polyethylene, polystyrene, polyethylene terephthalate and biotene (Biothene) compounds were evaluated by sampling at certain periods during a 600-day exposure period (in the shade and under sunlight, on land and in the seawater environment). While all samples kept in the land environment under sunlight decomposed faster than other conditions, it was observed that polystyrene was the fastest decomposing compound among these compounds. In addition, it has been reported that disintegration on land is faster than in seawater and direct light accelerates disintegration (Çelik et al., 2022).

2. Sources and Forms of Microplastics

Microplastics are divided into two groups according to their sources: primary and secondary microplastics. Primary microplastics are the name given to industrial microbeads of various sizes and are spread into the environment as contaminants during stages such as production and transportation (Andrady, 2017; Yurtsever, 2015). The main source of microplastics in oceans and seas is secondary microplastics (Barnes et al., 2009). These are released into the air, soil and seas as a result of the breakdown of plastic materials and garbage used by anthropogenic effects and/or natural effects such as water, air, wind and sun (UV rays) (Andrady, 2017; Esmeray and Armutçu, 2020).

Microplastics have attracted the most attention among plastic-derived pollutants in recent years. Microplastics can be found in many morphological forms, such as amorphous, spherical and long fiber forms (Abu-Hilal and Al-Najjar, 2009; Yurtsever, 2015). Most fragments found in tidal and estuarine sediments consist of fibers (Browne et al., 2011; Thompson et al., 2004). The shapes of microplastics vary depending on the duration of their residence in the environment as well as the degradation processes they undergo (Doyle et al., 2011). Microplastics also differ in many aspects such as size, composition, weight, physical and chemical properties (Esmeray and Armutçu, 2020).

3. Mikroplastiklerin Fizikokimyasal Özellikleri

Microplastics have properties such as having hydrophobic surfaces, floating ability, potential to carry pollutants, ability to absorb pollutants such as polychlorinated biphenyls (PCBs) and dichlorodiphenyltrichloroethane (DDT), UV photo-oxidative degradation, thermo-oxidative degradation, bio- and/or thermal degradation, and binding on biomass, especially in biofilms (Hidalgo-Ruz et al., 2012; Wright et al., 2013). Because they are essentially lipophilic, persistent organic pollutants accumulate in the fatty tissues of marine organisms. Due to these features, they potentially cause many negative effects (e.g. cancer, malformation, deterioration in the immune system and reproductive ability) for humans and other living things (Esmeray and Armutçu, 2020).

4. The Effects of Microplastic on Marine Creatures and the Food Chain

The gradual breakdown of plastic waste over time and the release of microplastics from various sources have the potential to have negative impacts on aquatic life and ecosystems. These infinitesimal plastic particles can be ingested by aquatic organisms, pass into the food chain, and cause harm to various

species, including humans. The prevalence of microplastic pollution stems from inadequate control of plastic use and disposal and has become a critical focus of environmental sustainability concerns (Bozma et al., 2023; Steensgaard et al., 2017; Hartmann et al., 2019; Soysal, 2024; Toussaint et al., 2019).

Aquatic organisms can become contaminated with microplastics (and nanoplastics) by consuming water contaminated with microplastics or by feeding on other organisms exposed to microplastics, leading to human exposure to microplastics. Additionally, fish can become contaminated during storage and transportation in flexible polystyrene plastic containers after catching (Revel et al., 2017). Plastic particles have been detected in various organisms from the lowest food chain, such as zooplanktonic organisms, to the highest levels in invertebrates (Crustacea, mollusks, etc.) and vertebrates (fish) (Esmeray and Armutçu, 2020; Van Cauwenberghe et al., 2013).

It is reported that microplastics will accumulate in biological tissues if they are continuously transferred from one trophic level to another. It is reported that marine creatures, especially those consumed whole, such as mussels, can be a vector for the transmission of microplastics to humans (Gedik and Eryasar, 2020). In one study, trophic transfer of labeled microplastics found in mussels to crabs was observed. Accordingly, it was observed that the amount of microplastics in crab tissues and hemolymph fluid increased in the first 24 hours. After 24 hours, 0.28% of the microspheres estimated to be retained by the mussel were detected in the crab hemolymph (Çelik et al., 2022; Farrell and Nelson, 2013).

In the study conducted by Nelms et al., microplastic transfer was observed from Atlantic mackerel (*Scomber scombrus*) caught in the Celtic Sea to grey seals (*Halichoerus grypus*) (Nelms et al., 2018). In the study conducted by Batel et al., it was reported that microplastic particles between 1 µm and 20 µm were transferred from artemia larvae (*Artemia nauplii*) to zebrafish (*Danio rerio*) (Batel et al., 2016; Çelik et al., 2022).

The presence of microplastics in seafood is a known fact and is the most important factor endangering food safety. Since microplastics are plankton-sized, they can be ingested by marine organisms (Farrell and Nelson, 2013; Naik et al., 2020). Marine creatures cannot break down microplastics with enzymatic activity after swallowing them, and these plastics continue to exist in the gastrointestinal system of the creature. Additionally, microplastic particles remaining in the intestinal tract block the tract and lead to decreased food digestion. It is predicted that this situation may reduce nutrition and energy assimilation in aquatic organisms (Browne et al., 2015) and, consequently, a decrease in the development and fertility of the organism may be observed. It has been reported that microalgae living in the sea are also affected by the presence of micro- and nanoplastics, and that the presence of microplastics in these organisms leads to a decrease in the photosynthetic activity of the organism (Sjollema et al., 2016).

Many marine mammals, invertebrates, fish-eating birds and fish ingest these microplastics. These plastic particles are seen in carcass dissection and especially in the digestive system. It has also been determined that micro- and nanoplastic particles can pass into surrounding tissues and organs through the circulatory system (Gülçiçek Uysal, 2021; Akçay et al., 2020; Lusher et al., 2017; Smith et al., 2018).

Studies examining the presence of microplastics in aquatic areas mostly focus on the digestive systems of organisms exposed to microplastics. This is because microplastics in the environment are ingested by aquatic creatures and become part of the food pyramid. Ingested microplastics have been shown to negatively impact development, accumulate in the liver and cause inflammation, and serve as a vector for the accumulation of adsorbed chemical pollutants (Lu et al., 2016; Zhang et al., 2017). However, more studies are needed on creatures such as marine mammals located at the upper levels of the food pyramid (Akdogan and Guven, 2019; Çelik et al., 2022).

Microplastics have the potential to be consumed and inhaled by humans, especially through the water and food chains. These particles can raise questions on the overall health of the organism through a variety of biological and toxicological effects. Additionally, there are concerns about the possibility that the chemicals contained in microplastics could cause potential toxic effects when ingested. However, the fact that research in this area is limited and clear results have not been reached highlights the need for further studies on the effects of microplastics on human health. In this context, the lack of

knowledge about the potential health risks of exposure to microplastics increases the importance of research in this area (Bozma et al., 2023; Muniasamy et al., 2023; Chowdhury et al., 2023).

5. What Methods can We Use to Dispose of Microplastics?

While 380 million tons of plastic are produced annually worldwide, less than 20% of this amount can be recycled. The breakdown of plastic waste into monomers by biological methods appears to be an efficient and economical method in the process of incorporating plastics into the reuse cycle (Çelik et al., 2022). Although there are different ways to dispose of the non-recyclable part, they are not sufficient in today's conditions.

Waste incineration: While the majority of plastics that cannot be included in the recycling cycle are disposed of in waste incineration units, some are accumulated in landfills, and a significant portion mixes with terrestrial and aquatic areas.

Density separation: Density separation is the process of separating the lighter materials from the heavier ones by using the buoyancy force of the liquid and the desired materials and other undesirable materials by taking advantage of the density difference after the mixture materials are thoroughly shaken (sodium chloride, sodium iodide, zinc chloride, sodium poly tungstate) and the liquid are mixed homogeneously. Density separation is a widely applied method to isolate microplastics from environmental samples, especially sediment samples (Hidalgo-Ruz et al., 2012; Crawford and Quinn, 2017).

Sieving: This is another frequently used method for isolating microplastics from water and sediment matrices. Sieves are usually made of metal such as stainless steel or copper (Wang and Wang, 2018). The sieve physically captures solid materials larger than the mesh size and removes water and smaller particles from the sample. The mesh size of the sieves mainly depends on the desired size range of microplastics to be collected, and most of them range from 0.035 to 4.75 mm (Esmeray and Armutçu, 2020; Hidalgo-Ruz et al., 2012; Zobkov and Esiukova, 2018; Rose et al., 2016).

Filtration: Filtration is a widely used and effective method for separating microplastic particles from liquids using a filter medium that only allows the liquid to pass through. The media used for filtration include glass fibers as the most commonly used filter and some other filters such as nitro-cellulose, polycarbonate membranes, zooplankton filters or isopore filters (Hidalgo-Ruz et al., 2012; Wang and Wang, 2018; Collard et al., 2017). The pore size of filters is generally between 0.45 and 20 mm. Although filtration is a simple process to separate microplastics from liquids, complications often arise as liquids are full of various microscopic particles or debris that can quickly clog the filter media, thereby reducing its effectiveness (Rose et al., 2016). This disadvantage can be mitigated by various useful measures, such as reducing the solution volume, settling the liquids for a longer time to facilitate the separation of heavier solid particles from the supernatant, and performing a pre-filtration step using a filter with a larger pore size. Additionally, it can be alleviated by adding some chemicals (e.g., iron sulfate) to the liquid to make the solid fraction precipitate (Esmeray and Armutçu, 2020; Wang and Wang, 2018).

Chemical methods for microplastic removal: Many wastewater treatment plants worldwide use coagulation and agglomeration processes to create larger pollutant particles that are easier to separate from water (Shirasaki et al., 2016). These processes include the use of Fe and Al based salts and coagulants to bind small particles through complexation mechanisms and thereby create strong bonds between waste particles (Chorghe et al., 2017). Ariza-Tarazona and colleagues (Ariza-Tarazona et al., 2019) investigated the removal of polyethylene microplastics from water using iron, aluminum salt and ultrafiltration. Experiments were carried out under different concentrations of Al^{3+} and Fe^{3+} ions, and the results showed that Al^{3+} had better performance than Fe^{3+} (Gülçiçek Uysal, 2021).

Biological Removal: According to the results of studies published to date, biodegradation of natural and synthetic macroplastics is possible (Ahmed et al., 2018). The fragmentation and size change of polyethylene microplastics ingested by Antarctic Krill, a planktonic crustacean, was studied by a group of researchers in Australia (Dawson et al., 2018). Although the type of degradation mechanism between microplastics and zooplankton remains unclear, it has been confirmed that smaller microplastics can be degraded very easily under environmental conditions (Ter Halle et al., 2016).

Paço and colleagues (2017) investigated the use of *Zalerion maritimum*, a naturally occurring fungus in marine ecosystems, for the biodegradation of polyethylene microplastics based on mass and size variations of microplastics in a batch reactor. Results obtained from biological content measurements, such as the decrease in protein amount and the increase in carbohydrates with exposure time, indicated that the *Z. maritimum* community probably used microplastics as a food source.

Microplastic removal with bacteria: The biggest disadvantage of plastic polymers is that they accumulate in nature without breaking down due to their largely inert chemical structure. Plastics are highly resistant to the hydrolysis of microbial enzymes due to reasons such as the low activity of the functional groups in the carbon-carbon skeleton that constitutes the polymers, the high hydrophobic character of the polymers and the low mobility of the groups within the polymer chain (Taniguchi et al., 2019). On the other hand, it is known that the cutinase enzyme, which breaks down the cutin layer in plants, can also exhibit hydrolytic activity on aromatic polyesters such as PET. The polyesterase activity of cutinase was first reported in 2005 by a German research group in their study using cutinase enzyme from *Thermobifida fusca* (Müller et al., 2020). Studies in the following years revealed that cutinase plays an important role in the hydrolysis of polyesters (Tokiwa and Calabia 2007; Zimmermann and Billig 2011; Baker et al., 2011). However, more than 50 years have passed since plastics came into use. It can be assumed that the microorganisms found in areas where PET and similar polymer wastes are concentrated have adapted to break down these polymers over time. It was determined that the PET hydrolysis activity of the enzyme called PETase was 120 times higher than the enzyme from *Thermobifida fusca* and 88 times higher than the enzyme from *Fusarium solani* (Çelik et al., 2022).

Auta and colleagues (Auta et al., 2017) investigated the removal of different structures of microplastics consisting of polyethylene, polystyrene, polyethylene terephthalate and polypropylene by *Bacillus cereus* and *Bacillus gottheilii*. Morphological and structural changes were investigated using electron microscopy and FTIR analysis, and the biodegradation rate was evaluated by measuring microplastic weight loss. The fastest mass reduction and shortest degradation half-life were found for polystyrene microplastics using the *B. cereus* isolate. According to the degradation results scanned by FTIR analysis, by comparing bond separations and chemical changes, it was revealed that the *B. gottheilii* species was the best in microplastic degradation (Gülçiçek Uysal, 2021).

DISCUSSION AND CONCLUSION

Studies show that micro- and nanoplastics are persistent pollutants in the environment and are accumulating in terrestrial and aquatic ecosystems at increasing rates. Pollution of oceans, land and aquatic systems with microplastics is not only considered an ecological damage, but also a threat to food security and, consequently, human health. Studies have shown that marine organisms in particular are exposed to high levels of microplastics (Akçay et al., 2020).

The use of synthetic textile products has become almost irreversible due to their affordability and practicality in meeting the needs of the growing population. But it would be good if washing machine manufacturers would at least do research and produce washing machines that can retain plastic microfibers to prevent synthetic textile fibers washed in washing machines from entering the sewer system. Additionally, control and research may be required regarding the production of synthetic textile products such as fleece, polyester, and fiber and the reduction of fibers that will shed during washing (Yurtsever, 2015).

Tackling this complex problem must include strong environmental education initiatives to raise awareness and understanding of the impacts of microplastic pollution. Additionally, it is critical to develop and implement more effective polymer waste management practices to limit the spread of microplastics in various ecosystems. To complement these efforts, there is a compelling need for ongoing research to identify, develop, and utilize effective and economically sustainable technologies to systematically remove microplastics from our environment. Comprehensive and collaborative

monitoring of these strategies can pave the way for sustainable solutions to mitigate the impact of microplastics on ecosystems and human well-being (Soysal, 2024).

Various actions such as environmentally responsible behavior, sustainable use of natural resources, reuse of waste, recycling of waste, separation and disposal are very important to prevent microplastic pollution. For a sustainable environment, production and consumption must also be sustainable. Conscious consumption and sustainable use of resources focus on achieving a certain quality of life and providing basic needs without endangering the needs of future generations.

ABSTRACT

Palm oil is a vegetable oil used for many food and non-food applications. The global demand for palm oil will continue to rise, owing to the growing population and expanding economy. To meet increasing demand, the area of land dedicated to palm oil production in producer countries in Southeast Asia such as Malaysia and Indonesia has increased steadily. Palm oil establishment in these areas has resulted in widespread deforestation, deterioration of ecological balance, and increased greenhouse gas emissions. To avoid these problems and fulfill the growing global demand for palm oil, voluntary certification under the International Roundtable Palm Oil (RSPO) and Malaysian Sustainable Palm Oil (MSPO) emerges as an efficient solution. These certifications aim to ensure sustainability, optimization of productivity and efficiency while adhering to transparency, ethical, and legal principles, respecting communities, supporting smallholders, and protecting workers while conserving the ecosystem. A related study examines the impact of sustainability-focused certification on product quality characteristics and stakeholder awareness in palm oil production. An assessment was conducted with approximately 104 individuals involved in the palm oil supply chain, either as producers or users. The assessment covered recognition of sustainability concepts, awareness of health benefits associated with palm oil and brand perception about certification in the context of purchasing products containing palm oil. This study has the potential to serve as a model for studies that will contribute to the advancement of conscious consumption and circular production in palm oil sustainability certification parameters. Preliminary results revealed that producers and consumers are aware of sustainability. Moreover, sustainability certification might positively affect brand recognition and purchase tendency for palm oil products. Developing efficient marketing and informative advertising based on scientific facts is crucial to maintaining and expanding awareness of the sustainability concept of palm oil and its products.

INTRODUCTION

Palm oil, widely used in food, cosmetics, and biofuels, has become a critical subject in environmental and health discussions due to its association with deforestation, biodiversity loss, and greenhouse gas emissions (Wiebe et al., 2019). To mitigate these concerns, sustainability certifications such as the Roundtable on Sustainable Palm Oil (RSPO) have been developed, aiming to promote environmentally responsible palm oil production (RSPO, 2021). Upon the demand of consumers for the use of certified palm oil; the Indonesian government introduced the Indonesian Sustainable Palm Oil (ISPO) standards in 2011, and the Malaysian government introduced the Malaysian Sustainable Palm Oil (MSPO) standards in 2015. In this direction, the establishment of well-planned and traceable palm oil production has a great determination on the protection of the environmental ecosystem in safe and healthy production (Ivancic and Koh, 2016). As of December 31, 2019, MSPO has become mandatory for all Malaysian palm oil producers and 639,407.61 hectares were registered as independent smallholders' plantations, 444,872.36 hectares were registered as organized smallholders' plantations,

and 3,600,781.46 hectares were registered as total certified plantations. (MPOCC, 2024a). Making MSPO mandatory ensures that producers adopt a standard; therefore, a rapid increase has been achieved. The main objectives of the MSPO certification include; management commitment and responsibility, health worker safety and employment conditions, compliance with legal requirements, development of new plantations, and transparency (MPOCC, 2024b).

However, the success of these initiatives largely depends on consumer awareness and understanding of the sustainability issues surrounding palm oil (Taufique and Vaithianathan, 2018). Research has shown that socio-demographic factors like education and income significantly influence consumer behavior towards sustainable products (Diamantopoulos et al., 2003; Zhao et al., 2014). Moreover, gender differences have also been observed, with women generally displaying higher environmental awareness than men (Hunter et al., 2004; Zelezny et al., 2000).

Consumers' understanding of sustainability certifications plays a vital role in shaping purchasing behavior. While some studies indicate that sustainability labels influence purchasing decisions, knowledge gaps regarding these certifications persist, limiting their effectiveness. (Grankvist et al., 2004; Hartmann and Apaolaza-Ibáñez, 2012). Younger and middle-aged adults, typically more engaged in sustainability issues, are key drivers of demand for eco-friendly products.

This study seeks to assess consumer awareness and perceptions of palm oil, focusing on the acceptability of palm oil, knowledge of its uses, and the role of sustainability certifications in shaping purchasing decisions. By surveying a diverse sample, the study provides insights into consumer behavior and the factors influencing sustainable purchasing trends.

MATERIAL AND METHODS

This study employed a cross-sectional survey design to collect data on consumer awareness, perceptions, and behaviors related to palm oil and sustainability certification awareness. The survey was distributed online and person to person, simultaneously to a diverse sample of 104 participants across various demographics. The questionnaire included sections on general awareness of palm oil (e.g., familiarity with palm oil used in products), understanding of sustainable palm oil (e.g., knowledge of RSPO certification), and purchasing behavior (e.g., the influence of sustainability claims on buying decisions). Participants were also asked to rate the quality of palm oil-containing products and to identify differences between palm oil and other related oils. All responses were examined and presented as percentages on graphs.

RESULTS AND DISCUSSION

The results of the survey are shown in graphs in Figures. According to the findings given in Figure 1, the survey's participant profile, predominantly female (68.26%) and concentrated in the 25-44 age range, reflects a well-educated and relatively affluent group, with 52.88% holding a master's degree or higher and 40.38% reporting high income. This demographic, often linked to greater environmental awareness and sustainable consumption behaviors, likely contributed to the high levels of awareness and preference for sustainable palm oil observed in the survey, indicating a group well-positioned to make informed, eco-conscious purchasing decisions.

Figure 1. General information about the survey participants

The demographic profile of the survey participants, including their higher education levels, income, and gender distribution, aligns with findings from prior studies that associate these factors with increased environmental awareness and sustainable consumption behaviors. For instance some previous studies highlight that higher education and income are strong predictors of environmental concern and the likelihood of purchasing sustainable products (Diamantopoulos et al., 2003; Zhao et al., 2014). Additionally, in some previous research, it was reported that women tend to show greater environmental awareness, which could explain the higher proportion of female respondents in the survey (Hunter et al., 2004; Zelezny et al., 2000). The predominance of young to middle-aged adults, who are typically more engaged in sustainability issues, further supports the survey's findings of heightened awareness and preference for sustainable palm oil among this demographic (Liere and Dunlap, 1980).

Figure 2. Palm oil acceptability of the customers

The results on palm oil acceptability among customers reveal a complex perception of this ingredient, which is influenced by various factors such as health concerns, awareness of its uses, and sustainability issues (Figure 2). While a significant portion of respondents (57.69%) do not believe palm oil is harmful to health, there is still a notable minority (30.76%) who perceive it as harmful, reflecting ongoing public debates and mixed information about palm oil's health impacts. Awareness of palm oil's uses is high, with 86.53% of respondents familiar with its applications, indicating that most consumers are well-informed about the prevalence of palm oil in products. However, there is ambiguity regarding the differences between palm oil and other oils, such as "hurma" oil, with respondents almost evenly split on this question, suggesting some confusion or lack of detailed knowledge about different types of oils. This response actually conflicts with the previous findings about how consumers are aware of palm oil, and its uses since "hurma oil" and "palm oil" technically address the same oil. Accordingly, it has been observed that a significant portion of consumers think that they have detailed information about palm oil and its uses, but even this simple difference in expression misleads consumers. This suggests that some marketing-oriented initiatives, such as advertising campaigns, significantly impact consumer perceptions.

These perceptions are crucial because they directly affect consumer behavior. For instance, while many consumers know palm oil and its uses, their health concerns and understanding of its sustainability aspects play a significant role in their purchasing decisions. The survey also shows that environmental sustainability (35.29%) and healthy living (32.35%) are key factors influencing purchasing decisions for products containing palm oil, reflecting a growing consumer trend toward products that align with personal health and environmental values. This aligns with previous studies, highlighting health and sustainability's increasing importance in consumer decision-making processes (Hartmann and Apaolaza-Ibáñez, 2012). Overall, the results suggest that while many consumers generally accept palm oil, its

acceptability is contingent upon ongoing concerns and knowledge gaps related to health and sustainability, which can significantly influence consumer preferences and behavior.

Although environmental issues positively affect the consumption of products containing palm oil, it has been seen that it is necessary to evaluate the price factor, which has a share in the consumption phenomenon, together with the product quality. When examined in this direction, the findings indicate a balance between the price and quality of palm oil products. The cost reduction in the prices of palm oil products has not been reflected in their quality at the same rate, and it has been determined that the effect of quality is moderate. The reason for this finding can be shown as the compatibility of palm oil processing methods with sustainability principles (Panapanaan et al., 2009; Gassler and Spiller, 2018).

Figure 3. Sustainability awareness and sustainability certification on palm oil

-The results on sustainability awareness and palm oil sustainability certification indicate a relatively high level of consumer engagement with sustainability issues, though there are notable gaps in understanding (Figure 3). A significant majority of respondents (74.03%) reported knowing what sustainable palm oil means, and 50% were aware of the specific sustainability advantages associated with palm oil. This level of awareness reflects a growing consumer consciousness around sustainability, particularly in relation to palm oil, which has been widely discussed in environmental and ethical contexts due to its impact on deforestation and biodiversity.

However, despite this awareness, there is still a considerable portion of the population that is either unaware or unsure about the specifics of sustainability certifications. For instance, 25.96% of

respondents admitted they do not know what the certifications on product packaging imply, and 24.03% are unaware of the sustainability advantages of palm oil. This suggests that while consumers are increasingly aware of sustainability as a concept, their understanding of the detailed implications of certifications and specific sustainability benefits is incomplete.

The influence of sustainability certifications on purchasing behavior is also evident, with 61.53% of respondents indicating that such certifications positively influence their buying decisions. This aligns with findings from previous research, which demonstrates that sustainability labels and certifications can significantly affect consumer behavior, especially among those already inclined towards environmentally friendly practices (Taufique and Vaithianathan, 2018). Nonetheless, the knowledge gaps identified suggest that for certifications to be fully effective in driving consumer behavior, further efforts are needed to educate consumers on what these certifications represent and how they contribute to sustainable practices. Overall, the results highlight the critical role of informed consumer education in enhancing the impact of sustainability certifications on purchasing decisions.

CONCLUSIONS

The results highlighted the significant role of sustainability certifications in shaping consumer awareness and purchasing behaviors related to palm oil products. The findings indicate that while there is a high level of general awareness about sustainability, gaps remain in understanding specific certifications and their implications. Consumers, particularly those with higher education levels and incomes, prefer products aligned with environmental and health values. However, misconceptions and incomplete knowledge about palm oil and related products persist, suggesting more targeted educational efforts are needed. Future research should focus on exploring the long-term impact of sustainability education on consumer behavior and how marketing strategies can more effectively communicate the benefits of sustainable palm oil. Additionally, examining the role of pricing and quality perception in sustainable product choices could provide deeper insights into consumer decision-making processes.

ABSTRACT

Today, studies carried out for the purpose of noise control and increasing sound comfort bring the importance of acoustic insulation to the forefront more and more each passing day. In this context, porous materials used to reduce or absorb sound energy in various engineering applications offer efficient solutions. In addition, the development of layered manufacturing (3D printing) technologies in recent years has made it possible to design materials with controllable acoustic properties and customized internal structures. In this study, the sound absorption performances of samples produced with 3D printing technology using PLA (Polylactic Acid) material with different volumetric porosity ratios were comparatively examined. Sound was given to the input end of the experimental setup at fixed frequencies and sound pressure levels were measured in dB at the output end. The effect of the change in porosity ratio on sound absorption was evaluated.

Keywords: Acoustic performance, Sound insulation, Porous material, 3D printing, PLA

INTRODUCTION

With increasing urbanization, industrialization, and technological advancements, environmental noise pollution has become a significant problem. According to the World Health Organization (WHO), long-term exposure to loud noise can lead to many health problems, such as hearing loss, sleep disorders, stress, lack of concentration, and various heart diseases (WHO, 2018). This highlights the need to ensure acoustic comfort in many areas, particularly residences, workplaces, transportation systems, and industrial facilities. Therefore, efforts to control sound insulation and sound are gaining increasing importance every day.

In this context, porous materials are widely used for sound absorption and damping, based on the principle that sound waves disperse within the material's internal structures and lose their energy. The acoustic performance of such materials depends on many parameters, such as pore geometry, porosity, and density (Islam et al., 2023). In particular, volumetric porosity directly affects the sound absorption capacity of a material, as it determines the amount of voids within the material's internal structure. In recent years, the development of additive manufacturing (3D printing) technologies has made it possible to design much more complex and customized internal structures compared to traditional production methods. This allows the acoustic performance of porous structures to be examined in a controlled manner, and materials with desired properties can be produced. In particular, the use of biodegradable and environmentally friendly thermoplastics such as polylactic acid (PLA) provides sustainable solutions both environmentally and economically. Some studies on the subject have investigated the acoustic performance of porous structures with different geometries produced using composite materials

such as PLA and various natural fibers (corkwood, hemp, coffee waste, etc.) using 3D printing technology (Kang et al., 2025; Lyu et al., 2025; Rezaieyan et al., 2024). Studies have shown that materials exhibit better acoustic insulation properties as the porosity ratio increases.

In pipe acoustics, the wave equation is obtained using the one-dimensional wave equation:

$$\frac{\partial^2 p(x, t)}{\partial x^2} - \frac{1}{c^2} \frac{\partial^2 p(x, t)}{\partial t^2} = 0 \quad (1)$$

where $p(x, t)$ is the acoustic pressure, c is the speed of sound, x is the position along the pipe axis, and t is time.

The behavior of acoustic waves within a pipe varies depending on the boundary conditions. In a pipe with both ends open, the fundamental resonant frequencies are expressed by wavelengths determined by the pipe length and are generally defined by the following equation:

$$f_n = \frac{nc}{2L}, (n = 1, 2, 3, \dots) \quad (2)$$

where c is the speed of sound, L is the pipe length, and n is the mode number. In pipes with one end closed, resonance occurs only at odd-numbered harmonics, and the fundamental frequency and upper harmonics are:

$$f_n = \frac{(2n - 1)c}{4L}, (n = 1, 2, 3, \dots) \quad (3)$$

These equations determine the frequencies at which sound waves within the pipe exhibit significant amplitude increases. In acoustic material testing, these governing equations are used as a reference for experimental observations and play an important role in evaluating the sound absorption or damping performance of different materials placed within the pipe.

In this study, PLA samples with different porosity levels were produced using 3D printing technology, and their sound absorption performance was experimentally investigated. In the developed experimental setup, a sound signal generated at specific frequencies was applied to the inlet end of the pipe, and the sound pressure levels at the outlet end were measured in dB. The decibel difference between the inlet and outlet was analyzed to evaluate the effect of changes in porosity on acoustic performance. The results provide guidance for the design of customizable acoustic materials using additive manufacturing.

MATERIAL AND METHODS

The test samples used in this study were designed as cylindrical shapes with varying volumetric porosity levels. The samples had an outer diameter of 45.2 mm and a thickness of 25 mm. Technical drawings of the samples are shown in Figure 1. Porosity was controlled by reducing the fill ratio of the sample's internal volume. They were produced in seven different groups with volumetric porosity ratios of 10%, 20%, 30%, 40%, 50%, 60%, and 70%, respectively. The designed samples and their nomenclature are given in Figure 1.

A FDM (Fused Deposition Modeling)-based 3D printer was used for sample production. The material used for sample production was commercially available biodegradable PLA filament. PLA is a frequently preferred thermoplastic in 3D printing applications due to its environmentally friendly structure, low melting temperature (~180–220 °C), and high print quality. PLA filament with a diameter of 1.75 mm was used in this study. Some printing and printer parameters used in sample production are listed in Table 1.

Table 1. Some printing and printer parameters.

Parameter	Value
Nozzle diameter	0.4 mm
Printing temperature	220 °C
Table temperature	50 °C
Printing speed	60 mm/s
Layer height	0.2 mm
Infill density	%30

The experimental setup and its schematic representation designed to evaluate the sound absorption performance of the samples are given in Figure 3. The samples were placed in a tight fit inside a cylindrical tube. Measurements were made by placing all samples inside the tube individually and then sequentially (from 10% to 70% (P10-P70) and from 70% to 10% (P70-P10)). During the experiment, a loudspeaker was fixed to one end of the tube, and sound was introduced into the tube at fixed frequencies (100 Hz, 200 Hz, 300 Hz, 400 Hz, 500 Hz, 1000 Hz, 2000 Hz, 3000 Hz, 4000 Hz, 5000 Hz, respectively). A dB meter was placed at the other end to compare the sound attenuation performance of samples with different porosity levels. Each measurement was repeated three times, and the average values were taken. For each measurement, sound pressure levels were measured both inside the empty pipe and after the sample was placed inside. The difference between these values was used to calculate the sound loss in

Figure 3. Experimental setup and schematic representation

RESULTS AND DISCUSSION

In this study, the sound absorption performance of PLA samples with different volumetric porosity ratios was evaluated using a pipe-type test setup. Measurements were made at a total of 10 different frequencies between 100 Hz and 5000 Hz. This wide frequency range is important for observing the acoustic behavior of porous materials at different frequencies. The output SPL values of the samples based on their porosity ratios are given in Table 2. The dB losses calculated based on the initial SPL are presented in Table 3, and their graphs are shown in Figure 4.

When the values in the tables and graphs are examined, it is generally seen that the sound pressure levels measured at the output end decreased as the porosity ratio decrease demonstrating that samples with lower porosity ratios exhibited higher sound absorption performance. The highest dB difference was measured at 2000 Hz for the P10 sample, 21.6 dB. However, the dB difference was not the same at all frequencies. For example, at 500 Hz, a 9.6 dB decrease was observed in the P10 sample, while a 2 dB decrease was observed in the P70 sample. At 100 Hz, a 1.3 dB decrease was observed in the P10 sample, while a 2.2 dB decrease was observed in the P70 sample. This demonstrates that material-sound interaction is frequency-dependent and that different porosity ratios should be optimized for different frequency bands. Furthermore, the increase in dB losses is generally more consistent with increasing frequency. This supports the possibility of porous structures being used as effective absorbers, particularly for mid- to high-frequency sounds. In this context, it was concluded that special-purpose acoustic panels can be produced by designing porosity appropriate to the targeted frequency range.

Analysis of the measurement results revealed that sound absorption was limited at low frequencies (100–200 Hz) at all porosity ratios. This may be attributed to the longer wavelengths of low-frequency sounds, which, in turn, interact less effectively compared to the material thickness. Experimental measurements have shown that higher sound pressure levels are achieved at the exit end of a pipe compared to an empty pipe at certain frequencies. While this might initially appear to increase the sound level, contrary to expectations, it can be explained physically by considering the effects of resonance, reflection, and impedance within acoustic systems. When a sample is placed inside a pipe, the internal acoustic environment of the pipe changes, creating resonant conditions at certain frequencies. In this case, sound waves accumulate within the pipe, creating a higher pressure level at the exit end. This effect is particularly pronounced in short pipes and at certain resonant frequencies. Furthermore, some samples with low porosity exhibit reflective surface properties, reflecting sound energy back, which can cause phase overlap within the system, leading to an increase in the dB value measured at the exit end.

Arranging the samples in different orders also significantly affected the system's acoustic response. The P70–P10 and P10–P70 measurements represent cases where all samples were arranged consecutively within the pipe without leaving any gaps. These configurations demonstrate the sound attenuation performance of multilayer porous material systems. At certain frequencies, these combinations yielded more effective results. For example, at 1000 Hz, a 10.3 dB increase was observed for the P10 sample, a 2.7 dB increase for the P70 sample, and a 7.6 dB decrease for the P70-P10 array. At 400 Hz, the dB difference between the P70- P10 and P10-P70 arrays was greater than that observed in individual measurements. This demonstrates that such combinations can be highly effective in acoustic panel design.

Table 2. Sound pressure levels measured in various frequency bands of samples with different porosity ratios

CONCLUSION

In this study, the sound attenuation performance of samples with different porosity levels produced from PLA material using 3D printing was experimentally investigated. By comparing measurements at different frequencies and the orientation of the arrays, the effects of material structure and placement order on acoustic performance were evaluated. The key findings of the study are summarized below:

- As the porosity level in PLA samples increased, sound transmission through the material became easier and sound absorption decreased.
- Samples with lower porosity showed more effective sound attenuation performance, particularly at mid- and high frequencies.
- The highest attenuation was observed in the frequency range of 2000–3000 Hz. In this range, the P10 sample significantly reduced the output dB level.
- Sample orientation had a significant impact on sound absorption. The high-porosity to low-porosity (P70–P10) arrangement yielded more effective results at mid- and high frequencies.
- PLA structures produced with 3D printing can offer effective and customizable solutions in acoustic applications by optimizing the porosity ratio and array direction

ABSTRACT

Plant by-products like sunflower seed husks and pomegranate peels are valuable sources of bioactive compounds, with significant potential for applications in food, pharmaceutical, and cosmetic industries. This study examines their biochemical profiles and bioactivities to promote sustainable resource utilization. Proximate analysis revealed distinct compositions: sunflower seed husks, with notably low moisture content, contrast sharply with the high-moisture pomegranate peels (over 80% water). Sunflower seed husks contain a higher lipid percentage, while pomegranate peels have minimal lipids. Both by-products exhibit comparable protein levels and total soluble sugars, highlighting their nutritional value. Antioxidant activity, assessed via DPPH scavenging, was significantly stronger in sunflower seed husks (approximately five times higher than pomegranate peels). However, pomegranate peels offered a substantially higher extraction yield, nearly four times that of sunflower seed husks. HPLC analysis identified diverse phenolic profiles: pomegranate peels were rich in catechin, ellagic acid, and rutin, while sunflower seed husks contained elevated levels of resorcinol and sinapic acid. Both demonstrated antimicrobial activity against *Staphylococcus aureus*, with sunflower seed husks showing roughly double the inhibition of pomegranate peels. These findings underscore the unique bioactive potential of each by-product, suggesting their valorization could drive innovation in functional products, reduce waste, and support circular economy goals. Further exploration of their industrial applications is highly promising.

Keywords: *Biological activities, Nutritional composition, Phenolics, Waste valorization.*

INTRODUCTION

The agro-industrial processing of sunflower (*Helianthus annuus* L.) and pomegranate (*Punica granatum* L.) generates substantial amounts of by-products, notably sunflower husks and pomegranate peels, which are often discarded or used as low-value animal feed (Gulya, 2004; Hasnaoui et al., 2014). This represents not only an environmental burden but also a lost opportunity to recover valuable compounds that could be exploited for food, pharmaceutical, and cosmetic applications. In the context of increasing global interest in sustainable resource utilization, the valorization of such by-products has become an important research priority (Mejri et al., 2025).

Plant by-products, such as sunflower husks and pomegranate peels, are considered promising reservoirs of bioactive molecules, particularly phenolic compounds, which are known for their antioxidant, antimicrobial, and anti-inflammatory properties. However, while pomegranate

peels have received some attention due to their high polyphenol content, studies remain fragmented, and sunflower husks in particular have been largely overlooked despite representing 21–30% of the total seed weight (Gulya, 2004). Recent investigations have further demonstrated the wellness-promoting potential of other underutilized plant matrices: Mejri et al. (2025) optimized the extraction of phenolic-rich fractions from date seed husks, spikelets, and perianths, reporting significant antioxidant and antimicrobial properties, while Ben Mansour et al. (2023, 2025) highlighted squash by-products, especially peels, as valuable sources of phenolics with strong bioactivities and developed encapsulation strategies to enhance their stability and applicability.

Among the most attractive bioactives, phenolic antioxidants stand out due to their role in mitigating oxidative stress, which is linked to the onset of chronic diseases such as cardiovascular disorders, diabetes, and cancer (Mansour et al., 2023). Antioxidants from plant sources also contribute to food preservation by delaying lipid oxidation, thereby extending shelf-life and improving product stability (Falleh et al., 2020). In parallel, antimicrobial properties of phenolic-rich extracts have gained increasing attention as natural alternatives to synthetic preservatives, especially against foodborne pathogens such as *Staphylococcus aureus* (Falleh et al., 2020; Ben Jemaa et al., 2022). Such dual antioxidant–antimicrobial functionality underscores the relevance of valorizing underutilized by-products like sunflower husks and pomegranate peels.

Despite their potential, systematic studies comparing the biochemical composition and bioactivities of sunflower husks and pomegranate peels are rare. Most available reports have focused on individual fractions, such as pomegranate peel tannins or sunflower oilseed husks, without addressing the broader valorization of husks and peels as bioactive-rich materials. This lack of comparative data limits our understanding of their respective advantages and possible complementary roles in functional product development. Addressing this gap is critical to advancing waste-to-resource strategies and supporting circular economy models.

In this study, we investigated the nutritional composition, phenolic profile, antioxidant activity, and antimicrobial potential of sunflower husks and pomegranate peels. High-performance liquid chromatography (HPLC) was employed to identify individual phenolic compounds, while radical scavenging and bacterial growth inhibition assays were used to evaluate bioactivity. By characterizing and comparing these two agro-industrial by-products, our work aims to highlight their potential as natural sources of bioactive compounds and to contribute to the growing body of research on sustainable by-product valorization.

State of the Art

The valorization of agro-industrial by-products has gained strong momentum in the last decades, reflecting global sustainability agendas and the increasing demand for clean-label, natural alternatives in the food, cosmetic, and pharmaceutical industries, with materials such as sunflower husks (hulls), pomegranate peels, grape pomace, olive residues, and coffee husks now considered valuable bioresources for functional ingredients rather than waste. This paradigm shift is underpinned by advances in green extraction technologies, encapsulation strategies, and an expanding body of evidence on health-promoting bioactivities. Modern green extraction methods have transformed the recovery of bioactive compounds, as conventional solvent extractions are increasingly replaced by environmentally friendly techniques that maximize yields and minimize ecological impact. Ultrasound-assisted extraction, microwave-assisted extraction, pressurized liquid extraction, supercritical CO₂, and deep eutectic solvents have all been employed to recover polyphenols, flavonoids, and dietary fibers, demonstrating clear advantages over conventional techniques in both efficiency and sustainability (Mejri et al., 2025). Ultrasound treatment accelerates solvent penetration into plant matrices, microwaves enhance mass transfer by disrupting cellular walls, and supercritical CO₂ provides residue-free,
